(4910) LIGNITE. Fossil wood carbonised to a certain degree, but retaining distinctly its woody texture, is thus disignated. A greater degree of change constitutes Cannel and Common Coal, in which the original structure of the constituent plants can only with difficulty be traced; a less change belongs to peat. Dr. M'Culloch observes:—"In its chemical properties Lignite holds a station intermediate between peat and coal; while among the varieties a gradation in this respect may be traced; the brown and more organised kinds approaching very near to peat, while the more compact kinds, such as jet, approximate to coal." ('On Rocks,' p. 636.) His synopsis of Lignite runs thus:—

A Jet. Hard, compact, with pitchy lustre.

B. Surturbrand. Less compact and more brittle than jet.

C. Moor Coal of some authors, Friable.

D. Bovey Coal. Fibrous, the vegetable texture very apparent, colour brown or brownish-black.

E. Cologne earth, earthy and pulverulent mass. The thickness said to be 50 feet.

F. Basaltic Coal. Of variable structure; some parts like wood, others like coal.

Lignite often occurs in beds of considerable thickness and extent, and supplies to particular districts a bad substitute for coal. It is often accompanied by iron pyrites (Alum Bay), lies in alternating series with arenaceous and argillaceous beds, and is sometimes covered by fresh-water limestone (Rapinach), and presents many analogies with coal, among the older rocks of the secondary series.—*Eng. Cyc. Vol.* III. *page.* 430. Lignite, or brown coal, has been found in several localities. On the banks of a small tributary of the Tenasserim, in about ten miles of latitude north of Tavoy, trunks of trees changed to lignite may be seen in the stiff clay, and near them the trunks of other trees completely silicified, and turned to stone. There is a great variety in this wood coal, both in its appearance and chemical analysis. Dr. Goodall, to whom Mr. Mason subjected specimens for analysis, wrote: "100 parts contain, 52 carbon, 29 bitumen, 19 ashes. The specimen was not good. It is good coal?" When Mr. Blundell saw several baskets of the coal that he had had brought in, he said it looked exactly like the first that was brought him from the Mergui coal field. This must be the coal referred to by the Coal Committee in their report for 1841, in which they say: "More recently, excellent specimens of coal have been presented to the Committee by Mr. Blundell, the Commissioner of these Provinces, as found somewhere on Tavoy river." No coal has been found on Tavoy river, and as this was the time when Mr. Blundell obtained the specimens of this lignite from the Tenasserim, there is doubtless an error in the reference to the locality. The Committee call it "Cannel coal," which only proves that lignite is sometimes "a perfect mineral coal;" that this coal is lignite, no one will question who has visited the

locality. The committee also reported on a specimen of coal from Maulmain as "Cannel coal," but Mr. O'Riley who visited the locality whence it was said to have been brought, says that if found in that neighbourhood, it must be lignite. Dr. Morton recently furnished specimens of lignite collected by the commander of the surveying vessel on the coast, below Amherst. As the shore there for many miles is covered with laterite, it is probably found in that rock. Lignite occurs in laterite on the other coast. Mr. O'Riley found lignite near the head waters of the Ataran. He says: "Approaching the head waters of the Ataran River, where the strata are considerably elevated, with the dipat an angle of 38° two separate lines of lignite occur in a coarse sandstone conglomerate with shale and a semi-indurated blue clay containing limestone pebbles. This lignite is highly pyritous, its decomposition affording a copious deposit of sulphate of iron which covers the exposed surface with a dirty-colored efflorescence. Some of the species taken from the deposit retain their original characteristics, do not fracture, and may be sawn through in sections across the grain, the same as wood imperfectly carbonized. Other deposits of wood less charged than the foregoing are found in the banks of the rivers Dahgyaine and Gyaine, some 20 to 30 miles to the north east of Maulmain, covered with the same blue clay as that already noticed, but none possess any useful quality as a combustible material."—*Masson.* Lignite occurs in great abundance around the coasts of the Indian Peninsula, in the recent strata.

(4911) LIGNUM ALOES, the eagle wood and Calambak of commerce, yielding an aromatic perfume, is furnished by the *Aquilaria malaccensis*, and *agallocha*, in Silhet, an ornamental evergreen shrub. A very high artificial value is placed on the better qualities of this product by the natives of the East: the best quality being worth about £14 the picul of 133 lbs. This fragrant wood is probably the lign aloes of the Bible. Incense to the value of nearly one million and a quarter francs was exported from Alexandria in 1837. Calambak or eagle wood, the true lignum aloes so highly esteemed in the East as a perfume or incense, is said to be produced by the *Aloexylum agallochum*, Lour. This remarkable wood contains a large quantity of an odoriferous oleo-resin; when heated it undergoes a sort of imperfect fusion, and exhales a fragrant and very agreeable odor. Its price in Sumatra is about £80 per cwt. Inferior specimens are obtained at Malacca. Eagle wood is also obtained from several other trees. The true eagle wood is however very scarce—*Simmonds, p.* 459. See AGAR, AGAL AQUILARIA, EAGLE WOOD.

(4912) LIGNUM-VITÆ or GUAIACUM, is a very hard and heavy wood. It is shipped from Cuba, Jamaica, St Domingo, and New Providence, in logs from 2½ to 36 in diameter, and is one of the heaviest of the woods. Col. Lloyd says, that it grows in the Isthmus of Darien to the size of 5 or 6 feet and is there called Guallacan, and that it is one of the most abundant woods of the country. When first cut, it is soft and easily worked, but it becomes much harder on exposure to the air. The wood is cross-grained, covered with a smooth yellow sap like box, almost as hard as the wood, which is of a dull brownish green and contains a large quantity of the gum guaiacum, which is extracted for the purposes of medicine. Lignum-vitæ is much used in machinery &c. for rollers, presses, mills, pestles and mortars, sheaves for ship blocks, skittleballs, and a great variety of other works requiring hardness and strength. It was employed by the Spaniards for making gun-carriages and wheels. The fibrous structure of this wood is very remarkable: the fibres cross each other sometimes as obliquely as at an angle of 30 degrees with the axis, as if one group of the annual layers wound to the right, the next to the left, and so on, but without much apparent exactitude. The wood can hardly be split, it is therefore divided with the saw; and when thin pieces, such as old sheaves, are broken asunder, they exhibit a fracture more like that of a mineral than an ordinary wood. The chips, and even the corners of solid blocks, may be lighted in the candle and will burn freely from the quantity of gum they contain, which is most abundant in the heart-wood. The Bahama lignum-vitæ has a very large proportion of sap-wood, pieces of 8 or 10 inches diameter have heart wood that scarcely exceeds 1 or 2 inches diameter. One variety of cocoa-wood and also the almond-wood are somewhat similar to lignum-vitæ.—*Tredgold.*

(4913) LIGUSTICUM AJOWAN. AJWAYAN. Is a species of lovage, cultivated about Ajmeer (and all over India), the seeds are highly carminative; promote the secretions; good in dyspepsia: much used in all mesalihs; eight seers for one rupee.—*Genl. Med. Top. p.* 124. Dr. Wight gives Ligusticum Ajowan, 566; and Ligusticum diffusum, 569.

(4914) LIGUSTRUM, a genus of Plants belonging to the natural order *Jasminaceæ*. It has a fleshy fruit, the berry containing two membranous 1-seeded nuts. The calyx is short, tubular, and 4-toothed; the limb of the corolla ½-parted and spreading; stamens two, with short filaments. The species are shrubs or low trees, natives of Europe and Asia.—*Eng. Cyc.* This genus has bitter and astringent leaves, and coloured berries, used in dyeing wines. The bluish colour they yield is very much admired.—*O'Shaughnessy, page* 435. Dr. Wight gives Ligustrum intermedia, 1245; macrophylla, 1245; ramiflora, 1245.

(4915) LIGUSTRUM JAPONICUM, is a native of Japan, with oblong ovate grooved

leaves, and white flowers growing to the height of 6 or 8 feet.—*Eng. Cyc.*

(4916) LIGUSTRUM LUCIDUM, is the Wax-Tree, a Japanese plant.

(4917) LIGUSTRUM SINENSE, has lanceolate tomentose leaves, white flowers, and very small brown berries. It is a native of China, near Canton.—*Eng. Cyc.*

(4918) LIGUSTRUM SPICATUM, has elliptic acute leaves, hairy beneath, as well as the branchlets. Flowers crowded, almost sessile, spicate, disposed in a thyrse, having the axis very hairy, and minute bracteas. It is an evergreen shrub, native of Nepaul, on mountains, growing from 6 to 8 feet in height. All the species of Privet are of easy culture, and will grow in any kind of soil. Cuttings root without difficulty. *L. lucidum* requires some protection in the winter. (Don, *Dichlamydeous Plants;* Babington, *Manual of British Botany;* Fraas, *Synopsis Floræ Classicæ*; Loudon, *Encyc. of Trees and Shrubs.*)—*Eng. Cyc.*

(4919) LILIACEÆ, *Lilyworts*, an important natural order of Endogenous Plants, containing many of the most beautiful of that class of the vegetable kingdom. A large proportion, especially of those of cold countries, consists of bulbous plants, producing annually a stem which perishes after having produced its leaves and flowers; others have an annual duration with perennial fleshy roots; and a few acquire, in warm countries, a stem of very considerable size, as the Dragon-Tree (*Dracæna Draco,*) of which there is an ancient specimen in Teneriffe with a stem many feet in diameter. The flowers of Liliaceous Plants are generally large and showy, especially in those with annual stems, as the Lily itself, the Fritillary, Hyacinth, Star of Bethlehem, &c.; but when they acquire an arborescent stem the size of the flowers contracts, so that the largest trees among them have the smallest flowers. Their leaves are always quite simple and undivided, and usually have the veins of the leaves running straight from the base to the apex; but in some Dracænas they diverge from the midrib to the margin, as in the Plantain. Among other Endogens they are readily known by having a flower of 6 coloured pieces, 6 stamens with the anthers opening inwards, and a superior 3-celled ovary changing to a 3-celled fruit. This order is divided into several sections, of which Dr. Lindley gives the following account in his vegetable Kingdom.—*Eng. Cyc. Vol* III. *p.* 431.

Tulipeæ are the *Liliæ* of Jussieu, and they may be justly regarded as the type of the order of Lilies. Bulbs: annual stems little or not at all branched; flowers usually large and gaily coloured, without membranous spathes, but axillary to leaves but little changed, the calyx and corolla and their parts scarcely united, although often arranged in a tube; anthers swinging lightly by the fine-drawn point of a stiff filament; and finally a dry seed-vessel—separate the group from all that follow. They are amongst the gayest of our garden flowers, as Tulips, Fritillaries, and Dog's-Tooth Violets testify. One of them, the *Lilium chalcidonicum*, a plant that covers the plains of Syria with its scarlet flowers, is most memorable from having been selected by our Saviour as the subject of allusion in his Sermon on the Mount. The *Hemerocalleæ*, or Day-Lilies, differ from the last in nothing except their calyx and corolla being so joined to each other as to form a tube of conspicuous length, and in their want of a bulb in many instances. The *Agapanthus* and the fragrant Tuberose are the more remarkable among them; but *Funkia*, *Hemerocallis*, *Blandfordia*, and the Veltheimias and Tritomas, are also species of familiar occurrence, *Phormium*, which yields the celebrated flax of New Zealand, with its hard perennial leaves and panicles of yellow flowers, must be considered to connect the present division with that of Aloes. There is so little to separate *Aloineæ*, or Aloes, from the Day-Lilies, that scarcely anything can be named except their succulent foliage, and even that disappears in *Yucca*, which has the hard leaves of *Phormium*, with which however its distinct sepals and petals forbid its being associated. With the *Scilleæ*, or Squills, we reach a division of the order abounding in beautiful species, all of which are bulbous, with annual stems. Their peculiarity consists in the anthers not being so lightly attached to the filaments as in *Tulipeæ*, and in the leaves from whose axils the flowers proceed acquiring a membranous condition. *Conantheræ* are squills with the ovary partially adhering to the calyx and corolla, and springing from tubers, not bulbs. They offer a direct transition to Amaryllids. *Anthericeæ*, or Asphodels, agree with the last in having tubers or fleshy fascicled roots, and not bulbs, but their ovary is free; they are therefore tuberous fibrous-rooted Squills. *Chrysobactron*, a genus gathered by Dr. Joseph Hooker in Auckland and Campbell's Islands, is described as dioecious, but apparently is polygamous. The fruit in these three last orders is a capsule.

Aphyllantheæ are plants with the habit of Rushes, and the bracts so membranous and closely imbricated as to give the appearance of Xyrids when the flowers are past. They seem to form a connection between Lilies and some plants of the Juncal or Xyridal Alliances. The genera have been very insufficiently examined. Xanthorrhœas, called Grass-Trees in Australia, are very different in habit from the remainder: their shrubby stems, which emulate small palm-trees in appearance, bear tufts of long wiry foliage at their extremities, from the midst of which rise very long cylindrical spikes of densely-compacted flowers, resembling Bullrushes. [TYPHA],

Asparageæ are Lillies with a succulent fruit. They consist of plants extremely dissimilar in appearance; the Common Asparagus and the Lily of the Valley being associated under this title. In general their leaves are broad; in the genus *Cordyline* they even acquire the expanded form and diverging veins of the Anomal Alliance; their stems, although among the dwarfest that the Lilies comprehend, are in the Common Asparagus branched and of considerable size, and in the Dragon-Tress they acquire the dimensions and age of large trees. A tendency to the separation of sexes occurs here on the part of the genus *Ruscus*, but it is not carried so far as to constitute a diclinous structure. With respect to *Aspidistreæ*, concerning whose structure we have very insufficient information, they are principally known by a large mushroom-shaped stigma. Their foliage is that of *Zingiberaceæ*. Their flowers are dingy purple or green, with a campanulate perianth, on whose sides the stamens are inserted. In many respects they are very like *Orontiaceæ*, to which perhaps they ought to be referred. In like manner the *Ophiopogoneæ*, or Teat-Worts, have a foliage hardly belonging to Lilies, *Peliosanthes Teta* resembling a Ginger more than a plant of this order. They are remarkable for their seeds bursting through the sides of the ovary at a very early period, growing freely though exposed to air, and finally acquiring the succulent appearance of a tuber. It is very uncertain whether they have any claims to the rank of Lilies. The geographical limits of this order are as wide as its differences of structure. Upon the whole however the species are much more abundant in temperate climates than in the tropics, where they chiefly exist in the arborescent state. Aloes are mostly found in the southern parts of Africa; one species is a native of the West Indies, and two or three more of Arabia and the East. Dracænas, the most gigantic of the order, attain their largest size in the Canaries; a *D. Draco* there is described as being between 70 and 75 feet high, 46½ feet in circumference at the base, and was known to have been a very ancient tree in the year 1804. The northern flora comprehends for the most part plants of the genera *Scilla*, *Hyacinthus*, *Allium*, and *Ornithogalum*. In the East Indies Lilyworts are rare; in Australia they form a distinctly-marked feature of the vegetation; and in New Zealand they are represented by the *Phormium*, or Flax-Bush. A very considerable number are employed for useful purposes. Among them are those whose fibre is strong enough to furnish cordage, such as *P. tenax*, New Zealand Flax. The Onion, Garlic, and Leek, long known as articles of diet, Chives, Shalots, and Rocambole, are species of the genus. Aloes and Squills indicate the value of some *Liliaceæ* in medicine. As purgatives the Aloes are in extensive use. Resinous matters are yielded by some species, whence they have been useful in dysenteries. Of these the most celebrated is Dragon's Blood, a tonic astrigent resin. The roots of *Asparagus racemosus* and *A. adscendens* are both employed medicinally in Northern India. *Polianthes tuberosa*, or the Tuberose, is well known for its delicious fragrance. Other species are found to contain special properties, which render them serviceable to man in various ways. There are 133 genera in this order, and 1200 species. (Lindley, *Vegetable Kingdom.*)—*Eng. Cyc.* Liliaceous Plants, from their generally ornamental nature, have attracted attention from the earliest ages to the present time, and our Saviour selected the flower of one of these (*Lilium chalcedonicum*) as a type of the beautiful productions of nature. The plants are usually herbaceous, though some few are shrubby, and even arboreous; most are distinguished by their narrow parrallel-veined leaves: of these, some are soft, herbaceous, and succulent; others hard and perennial. Of the latter many abound in fibre, which may be, and is, extracted for useful purposes; as Aloe, Sanseviera, Phormium, &c. of which we may give the following notices.

True Aloes Fibre.—True Aloes (*Aloe vulgaris, Barbadensis &c.*) The true genus *Aloe*, or the plants which yield the medicinal drug of that name, abound at the Cape of Good Hope, on the west coast of Africa, and on that of Arabia, with one or two species in India. They might be supposed to yield much fibre from the frequency with which we find the name applied to some of those met with in commerce; but these are in general the produce of a species of Agave commonly called American Aloe (*v.* p. 41, &c). The leaves of the true Aloes are, in all the countries where the species are indigenous, as well as in the West Indies, where one or two of them have been long introduced, cut up and boiled down to yield the *extract* called *Aloes*. In some cases the yellow juice is allowed to exude from the cut leaf to form what is called Socotrine Aloes; but nowhere is the fibre which these leaves undoubtedly contain turned to useful account. It is probably, however, that it might, even when the leaves are cut into small pieces, be separated at little expense, for the use of the paper-maker. That the fibre, as well as the tow, of the true Aloes is of a good and useful quality, is satisfactorily proved by the specimens of both prepared in Madras by Dr. Hunter, as those of the *kala-buntha*, or of the species which is there called *Aloe perfoliata*, and which is, probably, the same plant with red flowers which Dr. Royle named *Aloe indica*, and found in dry situations in North-West India. The fibre is white in colour, fine in quality, with sufficient tenacity for textile fabrics, and readily takes colours, as shown by the orange, red, and crimson-coloured specimens sent by Dr. Hunter. The fibres are about two feet in length, and have considerable strength. A bundle of the fibres

bore 106 lb., when a similar one of Petersburgh hemp broke with the same weight.—*Royle, Illustr. plants.*

Moorva Fibre, Marool of Madras (*Sanseviera zeylanica*). Bowstring Hemp.

Moorga and Moorgavee, Ben. | Marul, Tam. Murva, Sans.

Sanseviera is a genus of Liliaceous plants, of which individuals are very abundant on the coast of Guinea and of other parts of Africa; also around Ceylon, and all along the Bay of Bengal, extending thence to Java and to the coasts of China. The leaves are succulent, and abound in fibre remarkable for fineness and tenacity. Dr. Roxburgh purposed that the fibres might be called *Bowstring hemp* in England, because the natives of the Circars make their best bowstrings of them. *Sanseviera zeylanica* is the best-known species, and has been so called as being common on the Ceylon coast. From it has been distinguished *S. Roxburghiana*, common on the coasts of the Bay of Bengal, apparently on insufficient grounds. It is figured by Dr. Roxburgh himself under its former name in his 'Coromandel Plants,' ii, tab. 184. *S. lanuginosa* is probably a distinct species, the *katukapel* of Rheede ('Hort. Mal.,' vol. xi, tab. 42). which grows on the sands of the Malabar Coast, All are closely allied to each other, and to the African *S. guineensis*. Of this the fibres have been occasionally introduced into the markets of Europe, and by some thought superior to New Zealand Flax. They have been called African Bowstring Hemp. ('Himal. Bot.,' p. 391.) The Indian species of Sanseviera was first described by Sir William Jones, in the 'Asiatic Researches,' vol. iv, p. 271, under its ancient Sanscrit name of *Moorva*, and he says, that—"From the leaves of this plant the ancient Hindoos extracted a very tough elastic thread called Maurvi, of which they made bowstrings; and which, for that reason, was ordained by Menu to form the sacrificial zone of the military class." Dr. Roxburgh describes the plant as common on the jungly salt soils along the coasts, growing under the bushes, and easily propagated on almost every soil, from the slips which issue in great abundance from the roots, requiring little or no care, and not requiring to be renewed often, if at all, as the plant is perennial. The leaves, when thus cultivated, are from three to four feet long. The fibre, which extends their whole length, is separated from the pulpy part of the leaves. The natives place them on a smooth board; then press one end of the leaf down with one of their great toes, and with a thin bit of hard stick held between the two hands, they scrape the leaf from them, and very quickly remove every part of the pulp. This can also be removed by steeping the leaves in water till the pulpy parts rot, &c. Dr. Buchanan found apparently the same plant, but which he calls *Aletris nervosa*, employed for making cordage near Bangalore. Before the leaves are beaten to separate the fibres, they are steeped in water fifteen (others say five) days, in order to rot the useless parts; but with Dr. Roxburgh the fibres became discoloured by this process. Dr. Roxburgh sent drawings of the plant and specimens of the fibre (v. 'Obs.,' p. 18) as early as the year 1790 to the Court of Directors, and again in 1800 by Mr. Hebb: after he had cultivated a begah (*i. e.*, third of an acre of ground) with this plant. As full-grown leaves of three to three and a half feet long yielded about one pound of the clean fibre for every forty pounds of the fresh leaves, Dr. Roxburgh concluded that this plant might be cultivated with advantage. By another calculation he found that one acre would yield 1613 pounds of clean fibre at a gathering, two of which may be reckoned on yearly, in a good soil and a favorable season, after the plants are of a proper age. He also ascertained that a line four feet long, made of *moorva* fibre, bore a weight of 120 lb., when a cord of the same size, made of Russian hemp, bore only 105. The former, moreover, after 116 days' maceration, bore a weight of 30 lbs., when the latter was completely rotten. Dr. Roxburgh further observes: "Should it ever become an object of culture, a less expensive and more expeditious method of clearing the fibres from the pulpy parts of the leaves, than that of the natives above mentioned must be contrived." This seems to have been since done. For the Rev. J. Garrow, as quoted by Mr. Murray, states that, in the year 1831, during his residence in Cuttack, in the province of Orissa, he first by mere accident discovered that the leaf of the *Aloe Angustifolia*, it is not easy to ascertain what plant is meant, but it is probably only a variety of Agave, as no species of Aloe is known to be indigenous on that coast, of Linnæus, contained a quantity of long white fibres. Perceiving that this material possessed great strength, clearness, and tenacity, he caused some quantities of the leaf to be beaten out with mallets, and the fibres to be withdrawn, and in this way collected about three hundred weight of fine grass, the fibres severally running about three feet long. On taking this to Calcutta, Mr. Tapley, chief officer of the Thalia East Indiaman, then lying off that port, had some of it manufactured into ropes. On a fair trial of a three-stranded rope of this material with a similar one of Russian hemp, in raising two and a half hundredweight of spelter from the hold, the grass faithfully brought it up on three successive occasions; whereas, in applying the hempen rope, twice out of three times it gave way, and in the third trial lost one strand. Both Mr. Tapley and Capt. Biden, the commander, highly approved of the article, as did many commanders of ships of other nations

then frequenting the port of Calcutta. "On the writer's return to Cuttack he laid waste the whole of the aloe plant he could discover, without respect to species; and to save time and labour, passed the leaves through a *Pressing Mill* similar to that used for expressing the juice from the sugar-cane. He then caused them to be laid in heaps under water for some days, till the fleshy portion of the leaf was decomposed, by which means the fibres were more easily collected; they were then hackled and baled. In the course of a short time afterwards he discovered a short species of aloe, growing wildly and profusely in all the moist woods of the neighbourhood, which the native called *Moorgubbee*. On experiment, this plant produced a most beautiful fibre, as soft and as fine as human hair, but possessing notwithstanding, extraordinary strength and tenacity. He derived a great quantity of flax from this plant, which, when portioned off in hanks, bore a strict resemblance to raw silk; indeed, side by side, the difference could not be distinguished. It was this article that first induced the writer to turn his attention to the manufacture of cloth. He engaged two native 'Tantees,' or weavers, to construct a narrow loom for this purpose. They at first found some difficulty in the undertaking, but in the course of four or five days they produced as fine a piece of cloth as was ever beheld: one portion of it the writer presented to Sir Charles (afterwards Lord) Metcalf." The fibres of the Sanseviera may, from their fineness, combined with tenacity, be applied to a variety of purposes. Dr. Roxburgh at one time supposed, though erroneously, that they were identical with China grass. They are usually about two feet in length, but may easily obtained longer, if plants are cultivated. The fibres are firm, hair-like, and silky, and resemble those of the pine-apple most closely. The tow is excellent for paper-making. The natives of Bengal twist the fibres into a fine thread, upon which they string ornaments to be hung round the neck; those of the coast employ them for making bowstrings; and the Rajpoot thread is sometimes made of its fibres. They readily take dyes, as was some years ago shown by Miss Davy, and specimens dyed red, orange, maroon, and green, were sent to the great Exhibition by Dr. Hunter. who lodged others in the Government Central Museum Madras. Miss Davy, moreover, had some cloth woven with the fibres, after some difficulty, but the fibre was still too wiry, from imperfect preparation. The weaver, moreover, having neglected to separate the coarse from the fine fibres, gave the cloth an uneven and irregular appearance. But if the necessary care was taken with this, as with all other fibres, there seems no reason to doubt that it might be applied to the fabrication of fine cloths, in the same way as pine apple fibre. The fibre has been proposed for the packing of steam-engines, and its tow used to be, and perhaps still is, converted into very good paper at Trichinopoly. As the Moorva fibre is employed by the natives for their bowstrings, there can be no doubt of its possessing sufficient strength for rope-making. In some recent experiments, this fibre, in its untwisted state, bore 280 lb., when Agave fibre broke with 270 lb. Dr. Wight found some string made of the latter, broke with 362 lbs., while the Sanseviera broke with 316 lb., so that these two may may be considered as nearly equal to each other in strength. Attention was called to the fibre of Moorgavie by Mr. A. Bond, Master-Attendant at Balasore, who sent to the Marine Board of Calcutta some of the fibres prepared from the leaves of plants growing in the jungly salt soils along the coast from Kedgeree southward, informing the Board that he had found the fibre useful on board the Hon. Company's schooner Orissa, as it answered excellently for running gear. On the receipt of the samples, the Board having desired the Master-Attendant at Calcutta to submit them to trial, the latter reported that it was "not equal in strength to the Europe or Manilla hemp, but that it seemed to take hot tar as well as the latter, and would answer generally for the same purposes as those to which the Europe and Manilla cordage is applied." The following were the results obtained:—

Europe hemp, made of sewing twine (untarred)...	broke at	212 lb.
Harris's patent colonial bolt rope (tarred) Probably made of New Zealand Flax, v.p.58.	,,	204 ,,
Manilla hemp (untarred)	,,	188 ,,
Europe bolt rope (tarred).....	,,	168 ,,
Balasore fibre (untarred), at Calcutta, ...	,,	137 ,,
Ditto, spun by Capt. Bond (thumb line), ...	,,	135½ ,,
Europe rope (tarred), ...	,,	88 ,,

In a further report, Capt. Bond stated, that forty maunds of the fresh plant produced one maund of fibre. The expenses of the experiment were high, as the plant had to be brought to him from some distance (four miles) to the place where it was dressed, and the best methods of separating the fibre had not been followed. The natives being averse to a work which their forefathers had never taken in hand. The plants having been steeped for eight days, were beaten out on a stone or plank, and then taken to another tank of water to be washed, and then dried and combed. All these processes necessarily increased the expenses. Mr. Bond further ascertained that the steeping spoiled the colour of the fibre, at the same time that it diminished its strength. With some fresh specimens of the fibre he also sent two pieces of cloth, which had been woven from threads spun by

fishermen, which were irregular in thickness, and so, consequently, was also the cloth. From the abundance of this plant in many situations, from the ease with which it may be cultivated, and the facility with which the fibre may be separated and cleaned, there is no doubt that it could be produced as cheaply as any of the other fibres; and it has been shown that it is capable of being used for a variety of purposes, as for textile fabrics, and for string and cordage, as well as for paper-making. It is abundantly diffused, especially along the coasts, and its fibre was sent to the Exhibition from Assam and Cuttack, as well as from Madras, Coimbatore, and the Malabar coast. Besides the foregoing, many other Liliaceous plants might be adduced, as yielding useful kinds of fibre, and in quantities sufficient to repay the trouble of their extraction. But they are not indigenous or sufficiently abundant in India, though the fibres of some have been separated, and specimen submitted. As, for instance, of the

Yucca, or Adam's Needle Fibre.—Adam's Needle, or *Yucca gloriosa, &c.*, like others, seems sometimes to be called an Aloe. The species of *Yucca* are natives of the southern provinces of the United States, and being there exposed to extremes, are capable of living in the open air, both in Europe and India. They are conspicuous for their noble show of lily-like white flowers, as well as for their long sword-shaped leaves, terminated by a thorny point. They no doubt all abound in fibre, as some of a fine quality and strong in nature, has been sent from Madras, separated from the leaves of the *Yucca angustifolia*. Other species flourish as far north as in the Botanic Garden at Saharunpore. The fibres also take colour, as in the specimens sent from Madras, dyed red, orange, purple, and green. Fibre has also been separated from other species of Yucca, as *Y. aloifolia* and *Y. filamentosa*. These are amongst those which have received the name of silk-grass. Those sent from India are from two to four feet in length, and are rather wiry, or resemble those of the Agave more than they do the fibres of Bromelias.

New Zealand Flax, or *Phormium tenax*,—Belonging to this family of plants, may here be noticed, though it is not so well suited as many others, to the general nature of Indian climates, but it will enable us to make some useful comparisons. It was discovered by the celebrated Cook in New Zealand—as he says "the country produced a grass plant, like flags, of the nature of hemp or flax, but superior in quality to either; of this the natives make clothing, lines, nets, &c." It grows both on the north and the south coast. It was introduced in the year 1798 into the south of Ireland, and has been found to flourish on the west coast of Scotland, though European winters are occasionally too severe for it. The native name of the plant is *kowdi* or *kowrey*, while the fibre is called *muka*. The leaves of the plant are perennial, hard, sword-shaped, from five to seven feet in length, with a flower-stalk rising four or five feet above them, and bearing a profusion of yellow flowers, followed by triangular seed-vessels, filled with flat and thin black shining seeds. According to Salisbury, three-year old plants yield on an average, thirty-six leaves, beside offsets from the roots. Six leaves produced one ounce weight of dry fibres, after being scutched and cleaned; and he calculated that an acre cropped with these plants, three feet apart (but they could not be placed so near without interfering with each other), will yield more than sixteen cwt. "The leaves are cut when full-grown, macerated in water for a few days, and then passed under a weighted roller." The natives of New Zealand cut the leaves when full-grown, and separate the fibres while yet green. Mr. G. Bennett states that a lateral incision is made with a large shell on each side of the leaf, merely to cut through the epidermis, which is first removed, and then, what he calls the internal epidermis, probably a part of the cellular tissue, "which agglutinates the fibres, and, if not removed, deteriorates the flax.' The principal operation is scraping with the shell, and then separating the fibres with the thumb-nails, and then employing combs for a more minute separation. The fibres are subsequently dried in the sun, and are perfectly white; some stout and strong, others fine and silky. It is said that "the plant may be shorn of its leaves in the morning, and before the sun has set be ready for weaving into cloth." The same thing may, no doubt, be done with others of these naturally white endogenous fibres. Considerable quantities were at one time imported, and a factory was established by Capt. Harris for their manufacture, but the supply seems to have been irregular, and now to have fallen off rather than increased. Mr. J. Wood, in the year 1844, in a communication to the Agricultnal Society of India, called attention to the New Zealand Hemp, as a plant which was very hardy and would thrive in any soil or climate, but that it preferred swampy lands. He stated that it was often met with in New Zealand, thriving three or four feet under sea-water, (but it is also found at some distance from the sea shore). He therefore thought the locality of the Soonderbunds, extending from near Calcutta to the sea, to be well adapted for this plant; and which would be profitable in a country where labour was so cheap. But it seems to have been forgotten, in this, as well as in a paper in the first volume of the 'Transactions of the Society,' that a plant which flourishes so far south as New Zealand, and succeeds well both in Scotland and in Ireland, is not likely to do well in so tropical

a situation as that of the Goonderlunds. An interesting set of specimens of New Zealand Flax, showing the native method of preparing the fibre and of dyeing it black, were sent to the Exhibition of 1851, by Tohui, a New Zealand chief; and another, a very valuable and suggestive set of specimens of the fibre and its tow, by Mr. E. W. Trent (v. 'Illust. Col.,' xli, p. 197), which he described as having been separated entirely by machinery invented by himself. If this fibre can be so prepared, then it is evident that others of the same nature may be successfully treated in a similar manner. These fibres are applicable to a variety of purposes, either of a textile nature or for cordage, and will, like the other white fibres we have mentioned, take colour. The strength of the fibres is considerable, for in some experiments by De Candolle, in which, however, that of Agave is understated, there is no doubt that the New Zealand Flax, which bore 23-7, was stronger than either Flax or Hemp, which bore respectively 11¾ and 16¾. It has also the advantage of being lighter, but has the disadvantage of many of the white fibres of breaking at a knot. Mr. J. Murray, in his pamphlet on this plant, printed on paper made from its leaves, states that the ship Atalanta, which plied between Southampton and the Channel Islands, was completely equipped with cordage and rigging made of *Phormium tenax*. He further continues—"I have seen specimens of ropes, twine, yarn, lines, sail-cloth, sacking, bedtick, &c., made of *Phormium tenax*; also fine fabrics of various kinds, affording demonstrable evidence that its fibre is susceptible of being woven into tissues of the most delicate description, or manufactured into materials of the strongest and coarsest kind. The sails, cables, and running rigging of the beautiful model of the frigate presented by his late Majesty William the Fourth to the King of Prussia, were entirely formed of *Phormium tenax*. Capt. Harris's yacht, a perfect gem in naval architecture, was supplied with a mainsail composed of three different varieties of New Zealand flax, and the cordage made of *Musa textilis*," that is, of Manilla hemp,—*Royle Fib. Pl.*

(4920) LILIUM, of this genus, Dr. Wight, in Icones, gives, Lilium Neilgherrense, 2031-32: tubiflorum, 2033-4; Wallichianum, 2035.

(4921) LIMES.

Kerna neboo, Beng.	Limboo, Neemboo, Guz.
Cay-Tanh-yen, Coch.chin.	Jerook, Mal. [& Hind.
Dehi, Cyng.	Jambira. Sans.
Citronier, Fr.	Elimitchum pullum Tam.
Citrone Ger.	Nemma pundoo, Tel.

A species of lemon which grows in abundance in most of the West India Islands, and is also met with in some parts of France, in Spain, Portugal, and throughout India. The lime is smaller than the lemon, its rind is usually thinner, and its colour, when the fruit arrives at a perfect state of maturity, is a fine bright yellow. It is uncommonly juicy, and its flavour is esteemed superior to that of the lemon. Dried limes are used by dyers in some parts of India, to fasten and improve colours.—*McCulloch. Faulkner.*

(4922) LIME, ACID. Citrus bergamia,—acida, small lime. In Tenasserim the small acid lime is seen almost every where in abundance.—*Mason.*

(4923) LIME, Calx recens usta. Oxide of Calcium. Quicklime. Caustic or pure Lime.

Chaux, Fr. | Kalk, Ger.

Lime, in its pure form, is a greyish-white, earthy-looking mass, moderately hard, brittle; Sp. Gr. 2·3 – 3·03; having an acrid alkaline taste; corroding animal substances. When fresh burnt, it absorbs both moisture and Carbonic acid from the air; it will abtstract water from most bodies, and is hence often employed as a drying substance. Fresh burnt and slaked Lime, though easily procured, is seldom pure enough for medical use. White Carrara Marble, Calcareous Spar, Chalk, Shells, all yield good Lime. The heat being sufficiently great, the Carbonic acid is expelled and about 56 per cent. of Lime left in a caustic state, and tolerably pure: but, if shells have been employed, mixed with a little Phosphate of Lime and Oxide of Iron. Water being added, Lime cracks and falls to powder; the rest as in Hydrate of Lime.—*Royle.*

(4924) LIMESTONE. Granular limestone, is the marble of which the images of Gaudama are formed, which are usually called alabaster images. It is a primitive limestone which has not hitherto been found in the provinces; but is abundant near Ava.—*Mason.*

(4925) LIMES, SWEET. Sweet limes.

Shouk-cho, Burm. | Meeta Neemboo, Hind.

Are grown in some parts of Pegu to a very small extent, but as this and two other kinds of wild lime are indigenous to the forests in the northern parts of the province, it is probable that oranges might be cultivated with success about Prome and from thence to Meeaday. The same observation applies to the grape, of which several sorts of wild vine are found in the upper part of the province, so as to render the trial of grape vine very desirable.—*McClelland.* This the sweet variety, grows to the size of a large orange. It is easily propagated by seed. The juice of the fruit is very grateful to persons with fever, although rather tasteless. It will grow also from cuttings. The young shoots make a very good stock for orange grafts.—*Riddell.*

(4926) LIMNANTHES Limnanthaceæ. These flowers are from California, and are of yellow colour, with a border of white and ar

slightly fragrant, they are readily grown from seed as others annuals.—*Riddell.*

(4927) LIMONIA, a genus of Plants belonging to the natural order *Aurantiaceæ*, so called from the original Indian names, Neemoo and Leemoo, of the Lemon. Several of those described under this genus by Dr. Roxburgh have been referred to *Atalantia* and *Glycosmis*. The species still included are rather heterogeneous in nature, and will probably require further separation. As most of the family abound in essential oil, so the leaves of some of the Limonias are fragrant, and the fruit, though small, of *L. acidissima* and *L. crenulata* is very acid. *L. laurcola*, referred to this genus by Dr. Wallich, in his 'Plantæ Asiat. Rar.' t. 245, is remarkable as the only plant of this family found on the tops of cold mountains. The people of the Himalayas, remarking its highly fragrant leaves, fancy that it is by feeding on them that the musk-deer acquires its strong and peculiar flavour.—*Eng. Cyc.* Wight gives Limonia missionis, 175.

(4928) LIMONIA ACIDISSIMA. A shrub with pinnate leaves, and winged petioles; fruit small, size of a pea; an article of commerce, used as a tonic.—*Riddell.*

(4929) LIMONIA ALATA. *Aurantiaceæ.* Ill. 41.

Kat yelloo mitch marum, TAM.

Tree small but the wood is remarkably close grained, hard and heavy. It is a pale yellow or straw coloured, if procurable of adequate size would be very valuable.—*Wight.*

(4930) LIMONIA CARNOSA.

Taw-shouk, BURM.

The small fruit of this, not larger than a nut, is a favorite spice, known in the bazars of Bengal under the name of Keklani. It is only found in the Pegu district.—*McClelland.*

(4931) LIMONIA, FRAGRANT LIMONIA. On all the lands near the mouths of the rivers that are occasionally overflowed by the waters, a very handsome shrub of the orange family, with a fragrant white flower, and a small fruit like a lemon in miniature, is quite common; and ought to have a place in Indian garden plots.—*Mason.*

(4932) LIMONIA PENTAGYNA.

Chitraka, TEL.

A large timber tree, a native of the Circars Beng. &c.—*Rohde. M.S.S.*

(4933) LIMONIA PENTAPHYLLA. *Aurantiaceæ.* NAT. ASH-SHOURA. Lin.

Conchie pullum, TAM. | Gonjee pull, DUK.

The five leaved Limonia bears a smooth roundish red fruit about the size of a marble, eaten but not held in any estimation; easily propagated by seed.—*Ainslie, page 223.*

(4934) LIMULUS, a genus of animals belonging to the order *Crustacea*, and which, on account of its anomalous characters, M. Milne-Edwards placed in a family by itself, which he called *Xiphosura*. He arranged these at the end of his system, next to the suctorial Crustaceans. He observes that the singular animals which compose this small group are so remote from all the other Crustaceans that some naturalists have been inclined to exclude them altogether from that class, and arrange them among the *Arachnidæ*, and that in entirely rejecting this opinion it becomes necessary to isolate them as much as possible, and to form a particular sub-class, which is connected with that of the *Branchiopoda* and that of the *Trilobites*, but is distinguished from those Crustaceans and all the other animals of the same class by the character of its organisation. The natural position then of these Xiphosures should, in the opinion of M. Milne-Edwards, have been the Brachiopods, but he has preferred the place which he has assigned to them, in order that he might not break the connection which unites all the Maxillated Crustaceans. The *Limuli* undergo in their youth considerable changes of form. At first their is no sword-like or styliform tail, which in the adult *Limulus* equals, at least, the rest of the body in length; their abdominal buckler is rounded posteriorly, and the last pairs of false feet are not developed. M. Milne-Edwards observed this in the embryos on the point of exclusion from the egg, at which period the abdomen supports only three pairs of appendages. The species of *Limulus* inhabit the sea, and sometimes come upon the sandy beeches. They are found in the Indian and Japanese seas, and in the Atlantic, on the coast of north America; but they do not appear to have a higher range than 44° lat., and seem confined to the northern hemisphere. Their food consists of animal substances: and when stranded, they often bury themselves in the sand as a protection against the heat of the sun, which is soon fatal to them.

I. *Section.*—Species whose second and third pairs of jaw-feet (two first pairs of Latreille) are monodactyle in the male, and in which the moveable spines of the lateral border of the abdomen are of of two sorts, namely, very long and very short.

(4935) LIMULUS LONGISPINA. M. Milne-Edwards notices this as a species closely approximating to *L. Moluccanus*, but having the teeth or posterior angles of the abdominal buckler large and more regularly triangular; the external border of these teeth being nearly as long as the internal border, and their base much less wide than the space left between them and occupied by the caudal stylet. Upper surface of the abdomen covered with small spines; the tooth of its latero-anterior border large, and situated very near that which separates that border from the latero-posterior border; moveable spines of the six pairs in the males and of the first three

pairs in the female very long; last three pairs very short, but sharp in the female. Caudal stylet triangular and spiny on its borders. Frontal border of the male strongly notched and sinuous, so as to appear trilobate. It is found on the coasts of Japan, and probably of China. This is the Kabuto-Gani (Helmet-Crab) of the Japanese; Un-Kiie, or Umi-do Game, of the Chinese. *Section* II.—Species in which the third pair of jaw-feet are cheliform in both sexes, and in which the moveable spines of the latero-posterior border of the abdomen diminish gradually in length in both male and female. Second pair of jaw-feet monodactylous in the male. Caudal stylet triangular and spiny on its upper border.

(4936) LIMULUS MOLUCCANUS, the Molucca or Common King Crab. The cephalo-thoracic buckler is regularly rounded anteriorly in both sexes, and above showing three rows of small spiniform points, situated one on the median crest, the others on the crests which separate the occipital region from the lateral regions; the posterior and lateral borders finely dentilated. The abdominal buckler smooth above, and terminated by two very short teeth, the internal borders of which is very long, and the external border (comprehended between the point and the insertion of the last spine) very short; tooth of the latero-anterior border moderate, and situated towards the middle of that border; moveable spines of the latero-posterior border moderate, and all nearly of the same length in the male; the first three rather long in the female; but the last three extremely short, and much wider than they are long. Caudal stylet triangular, spiny on its upper border, and slightly concave on its inferior surface. Last pair of jaw-feet furnished towards the end with four elongated appendages, which are lamellated, flattened, and sublanceolate. (Milne-Edwards.) This is the *Cancer moluccanus* of Clusius; *C. perversus* of Rumphius; *Limulus Polyphemus* of Fabricius *L. gigas* of Muller; and *L. Moluccanus* of Latreille. M. Milne-Edwards is of opinion that Leach's *L. Latreilli* probably belongs to this species, as well as *L. tridentatus* of the same author, *L. Moluccanus* is apparently the *Cancer* figured by Bontius in the fifth book of his 'Natural and Medical History of the East Indies,' p. 83, in which he notices its sword-like appendages, and states that if any incautious fisherman is wounded by it the pain is like that caused by a scorpion, adding, that its flesh is not so delicate as that of the other Crabs. The chapter is headed by the following verses, which refer to the painful wound inflicted by the tail.

"Quisquis caudati sensisti tela Paguri,
Disce meo exemplo morsus vitare dolosos,
Dentis Icquino quos aula volubilis infert,
A tergo, et pejus retinet fors cauda venenum."

(4937) LIMULUS ROTUNDICAUDA. Cephalo-thoracic buckler wider than in the preceding species, less convex, and deprived of the series of small spines between the great teeth of its upper surface, but with a great number of these spiniform points scattered on the occipital region; terminal teeth of the abdomen short, and having their internal border about twice as long as the external border; the moveable spines nearly as in the preceding. Caudal stylet obscurely triangular, with rounded borders. (Milne-Edwards.) It is found in the Moluccas. It is the *Cancer marinus perversus* of Seba.

(4938) LIMULUS VIRESCENS. M. Milne-Edwards states that this species, the female only of which is known to him, bears a strong resemblance to *M. Moluccanus*, but is distinguished from it by the conformation of the posterior feet, the penultimate joint of which is extremely short, and surrounded at its base with seven spines, which, instead of being flat, very much elongated, and rather wide, are rounded, conic, and very much pointed. The first four pairs of feet were broken in the only individual which M. Milne-Edwards had examined, so that he could not verify the character indicated by M. Latreille, the namer and describer of the species, drawn from the monodactylous conformation of the second pair (the first pair of Latreille). It is also worthy of note, M. Milne-Edwards adds, that the cephalo-thoracic buckler is less convex than in the preceding species. The same author observes that the *Limulus* preserved in the Paris Museum under the name of *Polyphemus heterodactylus*, Lam., and ticketed by Latreille, seems to him to be the male of the preceding species: but the absence of the posterior feet prohibits positive certainty on this point.

(4939) LINARIA CYMBALARIA, Ivy-leaved Snap-dragon.

Karamba, Sans.

Given in India with sugar for the cure of diabetes. Lindley observes that Hamilton's remarks to this effect are probably applicable to the *Lin-ramosisima* of Wallich, a nearly allied species.—*O'Shaughnessy, p.* 477.

(4940) LINARIA RAMOSSISSIMA. In the same valley, the little yellow-flowered *Linaria ramosissima*, may be seen crawling over every ruined wall, as we see the walls of our old English castles clothed with its congener *L. Cymbalaria.*—*Hooker. Him. Jour. Vol.* I, *p.* 42.

(4941) LINARIA, Toad Flax. These are common plants, and may be easily raised from seed; colours, mostly, purple-blue and yellow. —*Riddell.*

(4942) LINDEN, Tribe: family *Tiliaceæ*. The *Tiliaceæ*, or Linden tribe, are so named from the well known European tree—a favorite in parks and public walks, and the source

of an extensive commerce, inasmuch as the mat which are imported in such enormous quanities, are formed of the bark of this tree. But in the same family with the Linden tree, botanists place also the genus *Corchorus*, species of which yield the now well-known Jute of India, as well as the genera *Grewia* and *Triumfetta*, both of which contain species remarkable for the tenacity of their bark. The Tiliaceæ are also remarkable for mucilaginous properties. The leaves of many are edible, and the fruit of some afford pleasantly tasted acid berries. If we inquire into the uses of these plants, we shall find, that as Lime leaves used to be, and still are, employed in some parts of Europe, both in a green and dry state, as fodder for cattle, so in the Himalayas, cattle are fed with leaves of *Grewia didyma*, and some are stacked for winter use, for cattle, sheep, and goats; as Dr. Royle when travelling there observed. As the inner bark of the Linden yields bast for mats, so is the inner bark of *Grewia oppositifolia*, called *bihul*, employed in the same mountains for making ropes. The Linden tree is not found in India; but there are many which belong to the same family of plants found there, some of which probably yield similar products, possibly one or two of those to which I now wish to draw attention. "Among the raw products sent from the province of Arracan, there were six kinds of Bast (which there seems to be called *Shaw*), with specimens of rope made with them. They were named—1, Theng-ban shaw; 2, Pa-tha-you shaw; 3, Shaw-phyoo; 4, Ngan-tsoung shaw; 5, Shaw-nee; 6, Eee-gywot shaw. Some of these, from their strength, flexibility, and softness, were well calculated to answer the purposes of the Bast in ordinary use, and specimens were sent to Dr. Lindley, to have their useful properties ascertained in the Horticultural Society's Garden at Chiswick. Both the Superintendents, Messrs. Thompson and Gordon, reported very favourably. The kinds sent to him were No. 2, Pastha-you shaw; 3, Shaw-phyoo; and one marked *Sanseviera zeylanica*, was probably a specimen from Cuttack. *Report upon new kinds of Bast-matting from India.* Hort. Soc. Gardens, Chiswick, January 11, 1854. "Sir,—The three pieces of Indian Bast sent appear all the same, at least I cannot detect any difference in their qualities or appearance; and I think, when it is made into mats, will prove an excellent substitute for Russian mats. It is very strong, is in broad strands, very pliable and tough when wetted, easily divided into small portions for the purpose of tying, &c., and is entirely free from knotty places; and when worked into mats in the Russian way, will be an excellent winter covering for pits and frames. The material, also, seems more firm and tough, and, I have no doubt, will last at least twice as long (in wear) as the best Russian mats; and, if sold at a less price will in time supersede them. "The price of Russian mats is now from £7 10s. to £8 per 100, wholesale; and from 2s. to 2s. 6d. each, retail. "A full-sized Russian mat weighs about 5 lb. when new and quite dry, is 7 feet long and 4 feet broad, and is made with the rougher and worst strands worked crossways, and the thinner and longer strands longways in the mats. "In making mats, it should be observed never to have any of them under the regular size, for small mats (either shorter or narrower) greatly detract from the value of full-sized ones when mixed with them. These basts were all sent in the state of bast, and twisted into rope, from Akyab in Arracan. The price of all stated to be one rupee a maund, or about 3s. a cwt. A knowledge of the good qualities of these Indian Basts might lead to their employment in India, and to their export to less distant countries than England. And it is possible that merchants in Arracan might wish to make mats in imitation of the Russian. The Arracan basts were as follows:

1. *Theng-ban shaw.*—Coarse-looking, and of a reddish-brown colour, but divisible into a number of very thin layers, with a good deal of flexibility, and some toughness. A portion twisted into rope.

2. *Pa-tha-you shaw.*—Strips seven feet in length, and fine in texture, light-coloured, formed of several easily divisible layers; the outer layers rather dense and compact, and the inner cancellar. A Musæ species (?).

3. *Shaw-phyoo.*—Long, thin, smooth layers, light-coloured, tough, and flexible; easily divisible into still finer layers.

4. *Ngan-tsoung shaw.*—Fibres and rope sent, but mislaid.

5. *Shaw-nee.*—Of a reddish-brown colour, rough and coarse, but twisted into rope.

6. *Eee-gywot shaw.*—Strips five to six feet in length, composed of several layers; of which one side is smooth and compact, but the layers on the other side thin but, cancellars, all having a considerable degree of toughness. Mr. Ripley, in 'Journ. Agri-Hortic. Soc.,' viii, p. 147, describes three barks under the names *Shaw-ne*, *Shawsphrus*, and *Batharan-shaw*. These may be Nos. 5, 3, and 2. But the spelling differs much. He also mentions several useful Rattans at Akyab. There are no doubt a great variety of other basts, which might easily be procured from trees in Assam, Arracan, and all along the Malayan Peninsula, as well as on the Malabar Coast. In an account by Mr. Fenwick of the vegetable products of the Tenasserim he mentions a bast rope of considerable strength, and also that plantains and pine-apples are very abundant there. All the above places are on the sea-coast, or accessible by river. But Akyab, where so many are already produced, seems the most favourable situation for their export to Europe, if it should be found desirable. It is probable

that several might be much improved by a little steeping in water, as practised with the Russian bast. Some of those sent to the Exhibition of 1851, and of which the plants are unknown, may here be mentioned.

Patoo or *Asta* is a bast from Beerbhoom, is like the Putwa from Bhagulpore, and will be noticed with it.

Chehoor, a pale, brownish-coloured cordage from Beerbhoom, coarse, and of moderate strength.

Bark string, made by Hill tribes of Rajmahl, of useful size and strength.

Bark rope with the coarse but strong fibre, of which it is made: also from Rajmahl. Several Bark cloths from the Islands, &c., are mentioned with the Paper Mulberry, formerly *Morus* now *Broussonetia papyrifera*. There is a remarkable cord without name, which seems to be formed of a salvage of fibre, with a yellowish bark folded or laid round it, and of these, two threads so made up are twisted into a cord. A bark like some sent as that of *Odina Wodier*, is full of fibrous material. One of the best of the basts, and seemingly as like one of those from Arracan, was sent from Assam; the strips are from six to seven and eight feet in length, consisting of several layers, easily separable, tough, flexible, and strong. They have the number on them of the box in which it was conveyed, and in which were contained Pine-apple fibre; but their appearance is totally different. Several of the basts of different plants which are used by the natives, and of which the names have been ascertained, will be found mentioned under the heads of *Hibiscus arboreus* or *tiliaceus*, *Sterculia villosa* and *guttata*, *Bauhinia racemosa* and *scandens*, *Celtis orientalis*, *Antiaris Saccadora*. Capt. Thompson reports upon a bast rope made by the Munneepoorees, and on another from Singapore. ('Journ Agri-Hortic. Soc.,' viii, p. 45.) At the Madras Exhibition of 1857, Mr. McIvor exhibited a useful bast prepared from the Acacia robusta growing at Ootacamund, and Mr. Jaffrey of Madras produced one of great strength from the Eriodendron anfractuosum. The inner bark of m ny trees is employed in other parts of India for the same purposes, though it is not easy to identify the plants, from only local names being usually given by travellers. Thus, in the following account given by Capt. Biddulph in a letter to the Agri-Horticultural Society of India, in the year 1843, he states that, near Darjeeling, "the Lepchas make rope from the fibre of the *Kullyhain*, and stout bowstrings and sewing thread from the fibre of the *Ruffickee* tree." "Nothing can be more simple," Capt. Biddulph states, "than their mode of manufacture: the bark is torn off the *Kullyhain* when from five to fifteen years' growth; the inner bark of fibre is then detached, as shown in the specimen, washed for a few minutes in water, and when dry, pared or pulled into narrow strips, and twisted by the hand into rope of any thickness. The bark of the *Ruffickee* is taken off the plant when five or six feet high, and treated in the same manner as the former, except that the outer bark only requires to be scraped off with a knife. All the Lepcha fishing nets are made from the *Ruffickee*, and are remarkably light and strong." Among the Mallow tribe (or *Malvaceæ*), and some allied families, there are several other instances of the same kind. —*Royle Fib. Pl. pages* 233 *and* 236.

(4943) LIME OR LINDEN TREE (*Tilia europæa*). The Lime tree abounds in the forests of Europe, but especially in those of Russia; and is esteemed for its sweet-scented flowers. The wood of the tree is white and light, and employed for making furniture, for turning, and for carved works. The bark of these trees when steeped in water soon separates into thin layers, which are employed for making a coarse kind of rope, for making matted shoes much worn by the Russian peasantry, and also for making the mats which are so largely exported from Russia, and which are so extensively used in England for packing furniture, as well as for gardening purposes, and for covering the floor. A Linden shoot growing in moist situations, is stated by Mr. Tooke as not fit for peeling, for the purpose of being platted into shoes, in less time than three years. To every pair of shoes, from two to four young Linden stems are requisite; and though these grow faster as they are cut, yet the consumption is enormous, and the destruction of the Linden tree is in consequence immense. For the better, larger kind of mats, trees of from eight to sixteen years are cut down when full of sap, and the bark is immediately separated both from the tree and the branches. It is first cut longitudinally, then raised with an instrument made of bone, and then torn off with the hand. When the bark has been removed, it is stretched on the ground to dry, two or three strips being laid one over the other, and kept straight by being tied down to long poles. They are employed for making ropes in some parts of England, and for well-ropes in France. When required for use, they are steeped in water, and the cortical layers readily separate from each other. The best of these layers are those which are in the interior, while the coarser layers are on the outside. The manufacture of mats is nearly confined to Russia and to some parts of Sweden. Trees of from six inches to one foot in diameter are selected in the woods, and in the beginning of summer the bark is stripped from the trees in lengths of from six feet to eight feet. These are afterwards steeped in water, till the bark separates freely into layers; it is then taken out and separated into ribands or strands, which are hung up in the shade—

generally in the wood where the trees grew from which they were taken; and in the course of the summer they are manufactured into mats. The fishermen of Sweden make fishing net out of the fibres of the inner bark. The trees from which the bark is taken are cut down in the summer, and, properly cut, are burnt in heaps into charcoal. The sap is drawn off, and, when evaporated, yields sugar. The honey of the flowers is much sought after by bees. The Lime tree is principally produced in the government of Vialka, Kostroma, and those immediately contiguous and in the months of May and June—the period when the bark is most easily detached from the stem—the villages in the governments in question are almost deserted, the whole population being then in the woods employed in stripping the trees. The academician Koppen, who has carefully investigated this curious subject, estimates the average annual production of mats in European Russia, as follows:

Government of Vialka	6,000,000	pieces.
„ Kostroma	4,000,000	„
„ Kasan	1,000,000	„
„ Nijni Novgorod ...	1,000,000	„
„ Vologda, Tamboff, Simbirsk, and Penza	2,000,000	„
Total	14,000,000	„

Koppen further estimates that about a fourth part of this vast quantity, or 3½ millions, are exported, the rest being consumed at home. Archangel is the principal port for the shipment of mats, and it appears that on an average of the years 1851 and 1852, the export of mats from that port amounted to 615,360 pieces a year. Large quantities are also shipped from Petersburgh, Riga, and other ports. (M'Culloch's 'Com. Dict.') The extent of the Imports of Russia Mats into Great Britain may be judged of by the following statement furnished to Dr. Royle by Messrs. Wrench:

1832 . .	840,000	1847 . .	520,359
1840 . .	817,772	1848 . .	397,553
1841 . .	598,485	1849 . .	576,565
1842 . .	532,401	1850 . .	359,223
1843 . .	861,565	1851 . .	734,659
1844 . .	449,817	1852 . .	333,008
1845 . .	634,041	1853 . .	657,040
1846 . .	898,619		

The price in Jan., 1834, was £4 10*s.* per 100, the duty included; in 1848, 95s. to 100*s.*; and in 1849, under 80*s.* In 1850, 90*s.*; 1851, 87*s.* 6*d.*; 1852, 85*s.* to 100*s.*; and in 1853, 120*s.* per 100.—*Royle Fl. Pl. p.* 233.

(4944) LINEN.

Lynwaat, Dut.	Panno de linho, Port.
Toile, Fr.	Polotno, Rus.
Linnen, Ger.	Tela de lino, Sp.
Tela, It.	

A species of cloth woven from the fibres of

the flax plant; though the term is now understood to comprehend all kinds of hempen cloth. The chief seats of manufacture are, Dundee in Scotland, Leeds in England, and Belfast in Ireland.—*Faulkner.*

(4945) LINSEED, Flax Seed.

Buzruk, Arab.	Tukhm-i kutan, Pers.
Lynzaad, Dut.	Siemie, lniane, Pol.
Horrfroe, Dan.	Linhaca, Port.
Lin, Graine de Lin, Fr.	Semja lenjanie, Rus.
Leinsaat, Ger.	Uma, Atasi, Sans.
Suf, Tisi, Ulsee, Guz. Hind.	Linaza, Sp.
Linseme, It	Alleverei, Sirru sanulverei, Tam.
Lini semen, Lat.	Alivi Tuma, Tel.
Bidgirammee, Mal.	

The produce of the flax plant consists of small, bright, grayish-brown, slippery, elongated bodies, containing a mealy, oleaginous albumen, which yields by expression oil in such great abundance, that the seeds form for this purpose, as well as for reproduction, an important article of trade. It is grown in small quantities in the United Kingdom, but Russia, Prussia, Italy, and India, are the great producing countries; in N. America, Sweden, Denmark, Turkey, and Egypt, it is also grown in small quantities. Linseed is largely exported from Bombay to England and France.—*Faulkner.* The seed of the flax plant, in India, its principal product, is principally used in the manufacture of Linseed oil. The first export from Calcutta was made by Mr. Hodgkinson in 1832, and amounted to only ten bushels, but the increase has been rapidly progressive.

1832,	ten bushels.	
1833,	2,163	maunds.
1834,	2,826	„
1837,	32,327	„
7839,	167,601	„
1850,	765,496	„

In the year 1850-51, the amount of Linseed imported from the Concan into Bombay alone was 59,076 cwt, and in the year 1851 the total imports into England of this product, was 93,814 cwt, and in 1852-53, 114,309 cwt: the one-sixth part of the total amount imported into England in that year. The value of the Bombay exports in 1850-51 was Rs. 170,112, and in 1852-53, Rs. 342,926. See Flax.

(4946) LINSEED OIL. Linum Usitatissimum.

Alliverie yennai, Tam.	Ulsee ke Beenj, Hind.
Aveesee noona, Tel.	

Linseed Oil, is contained in the kernel of the seeds of the flax plant, Linum usitatissimum, and may be either cold drawn, or, as is usual, obtained after the seeds have been subjected to a heat of 200°. The oil obtained by the former process is paler, with less colour and taste, than where heat has been employed. The seeds of different countries yield different proportions of

oil, as the following yields from a bushel of seed wil show:—

	yield of oil. lbs.
East Indian Seed, ...	14¾ to 15.
Egyptian, ...	15
Sicilian, ...	14

When cold drawn, it is greenish-yellow, and more viscid than when hot drawn. It is one of the cheapest fixed oils; and is used in the manufacture of paints, varnishes, and printing inks. It is what is called a drying oil. Linseed oil is imported into Bombay from England. That made in the country is considered much inferior to the English oil.—*Faulkner*. The seed from which this oil is expressed, has long been cultivated to a limited extent in Nagpore, Bellary and other parts of the Madras Presidency. There is an impression that the oil obtained from the Indian plant is inferior to that imported from England, but it will be found on experiment, that this arises from the former having been imperfectly freed from mucilage, which prevents its drying. The seed is now an article of export to the amount in 1852-53, of cwt. 1,106. At the Madras Exhibition of 1855, the Rajahmundry Local Committee, Lieutenant Hawkes, and the Madras Tariff exhibited excellent samples of this oil. It is said to be procurable in Bellary at Rs. 3-8-0 per maund. In the year 1852-53, English Linseed oil to the amount of galls 4-552 and valued at Rs. 8,763 was imported into Madras, whilst at the same time cwt. 1,045 of the seed were exported from hence mostly to England, it appears that it can be made on the spot for much less than the average value of the English oil. This fact, it is hoped, needs only to be pointed out, to be taken advantage of It would, however, be necessary to guard against the adulteration of this oil, with any of the other greasy oils which would of course infallibly destroy its drying properties.—*M. E. J. R.*

(4947) LINSEED OIL CAKE. The substance which remains after the oil is expressed from Linseed, contains the albuminous part of the seed, and is used for fattening cattle.—*Faulkner*.

(4948) LINUM, a genus of Plants which gives its name to the small family of *Linaceæ*, and is characterised by having 5 distinct sepals, 5 petals, 5 stamens, and from 3 to 5 styles, which are either distinct from the base, or united as far as the middle, or even the apex. Capsule globular, divided into 10 cells, each containing a single seed. Herbs or small shrubs; leaves entire, without stipules; flowers having the petals falling off shortly after flowering. The species are chiefly found in Europe and the north of Africa, but a few likewise in other parts of the world. Few of the species of *Linum* are of any importance, except that which has been an object of culture from the earliest times of which we have any record, that is *L. usitatissimum*, the Flax Plant, which is valuable as well for its seed, as for the ligneous fibre of its cortical layer, which forms the tow spun into yarn and woven into linen cloth. It is distinguished by its glabrous capsules within the sepals; ovate pointed ciliated lanceolate leaves, and solitary stem. The flower is blue; stem from one to one and a half feet high; sepals 3-nerved. It is a native of Great Britain. It has been sometimes said that cotton is the substance from which cloth was made in Egypt in ancient times. Cotton was no doubt known to the Hindoos at very early periods, and may have formed an article of commerce to Egypt from India, but that it was not much used is proved by none of the mummy cloth, which has been examined by the best microscopes, being found to be composed of cotton. The seed is valuable for the condensed mucilage contained in its seed-coats, while the almond contains a fixed oil, valuable for burning, and in the arts as a drying oil; the oil-cake is used for fattening cattle. Linseed is extensively imported from Russia, Italy, and Egypt, for crushing, but of late years it has been imported in large quantities from India for the same purpose, this is found to yield a larger proportion of oil than Russian linseed, and the commerce will no doubt continue to increase. Seed is also imported from Holland, America, and other places for the purpose of sowing, as it is found to yield a finer and more abundant crop than the British seed. It is curious that the Hindoos make no use of the ligneous fibre; but the plants, though they there produce fine seed rich in oil, are very dwarfish, and may not therefore be found profitable culture for a people who have cotton in such abundance, and who wove it into cloth in ages when even linen was unknown in Europe.—*Eng. Cyc.*

(4949) LINUM ANGUSTIFOLIUM is found in sandy and chalky places. It has downy capsules within the sepals, elliptical, pointed, ciliated; leaves linear-lanceolate; stems numerous. Flowers of a pale blue; stem one or two feet high.—*Eng. Cyc.*

(4950) LINUM AUSTRIACUM. Some of these flowers are pretty, and may be placed in a border, the flax is well known.—*Riddell.*

(4951) LINUM PERENNE, has obovate-obtuse sepals obscurely 4-nerved, glabrous, leaves linear-lanceolate; stems numerous; fruit stalks erect. Flowers blue; stem one to two feet long, erect, or decumbent. It is found in chalky places in Great Britain.—*Eng. Cyc.*

(4952) LINUM USITATISSIMUM.

Atees, Tisi, Mushina, Hind. and Beng.

Linseed oil is one of the chief ingredients in oil varnishes and in printer's ink; by boiling with litharge its drying properties are much improved. It does not seem improbable that the spurious white "atees" roots of the bazar are occasionally obtained from this article, or from

the *Goolashoopre*, or Linum trigynium, indigenous in the Lower Provinces.—*O'Shaughnessy, p.* 213. At the Madras Exhibition of 1855, several specimens of true Flax from the Linum Usitatissimum were exhibited from Tanjore, Ganjam and the Nizam's Territories, but none of them were clean or of good quality all having been stained by rotting. This is to be regretted as the fibre was of good length and is said to be procurable in large quantities in Goomsoor and the Nizam's territories, if previous notice be given to the cultivators.—*M. E. J. R.*

(4953) LIQUIDAMBAR, a genus of Plants belonging to the natural order *Balsamifluæ* of Blume, which has been altered to *Balsamaceæ* by Dr. Lindley. The name is derived from 'liquidum,' fluid, and 'ambar,' the Arabic name of amber. The genus is closely allied to the Willow and Plane tribes, but distinguished from both by its 2-lobed 2-celled many-seeded capsules, and their albuminous embryo. The species are only three in number, all forming fine trees, and occurring in Java, the Levant, and North America.—*Eng. Cyc.*

(4954) LIQUIDAMBAR. The Liquid-amber of commerce is a product of three species of plants belonging to the natural order of Balsamifluæ of Blume which has been altered to Balsamaceæ by Dr. Lindley. The name of this substance is derived from *Liquidum*, fluid, and *Ambar* the Arabic name of Amber. The three species all form fine trees, and occur in the Levant, Mexico, North America, Java and Tenasserim. Liquidambar altingia is a superb forest tree, occurs on the mountains of Java, at elevations of 2000 or 3000 feet above the level of the sea, also on the coast of the Tenasserim provinces, where it is indigenous, and in some places quite abundant, (Malay, Rasamalay, Burmese nan-tu-yoke). Indeed a considerable stream in the province of Mergui derives its name from this tree in consequence of its growing so thick on its banks. The bark of L. altingia has a hot and bitterish taste, and yields a fragrant balsam or liquid storax although there is no proof that the liquid storax, known in Europe is obtained from it, and it does not grow near the localities where liquid storax has so long been obtained. Liquidambar styraciflua a large, fine tree, is the species found in Mexico, and the United States, in the latter of which it is called sweet gum, and the fragrant liquid exudes, though not very copiously, from incisions in the stem. This is called Liquidambar, oil of Ambar, and Copalm Balsam, and in this form has a pleasant balsamic odour and an aromatic bitter taste. This becoming dry, forms what is called soft or white Liquidambar, which resembles very thick turpentine, has a feebler odour than the liquid balsam, and contains less volatile oil, but more benzoic acid. Liquidambar orientalis is a native of Cyprus and parts of the East Indies. Dr. Pococke, as quoted by Dr. Lindley, states that it is called Xylon Effendi (the Wood of our Lord), in Cyprus, where it produces an excellent white turpentine, especially by incisions in the bark. It is also said to be produced on the islands of Cabross, at the upper end of the red Sea, near Cades, which is three days' journey from Suez. The product of the L. Altingia is said to be mixed with the substance obtained by boiling the branches of Styrax officinale, or acting upon them with oil, spirit or naphtha. The subject is interesting as connected with ancient commerce, inasmuch as old writers mention a liquid with the solid storax, the mia-saileh and Mia yabseh of the Arabs. In all its states Liquid-amber is used to mix with Balsam of Peru.—*Eng. Cyc.* —*Mason.*

(4955) LIQUIDAMBAR ALTINGIA,
Rasamala, Malay.

of Blume, is a native of the forests of Java, at elevations of 2,000 to 3,000 feet above the level of the sea. It forms a gigantic tree, with bark having a hot and bitterish taste, yielding a fragrant balsam, or liquid storax, the Rasamala of the Malayan Archipelago, though there is no proof that the liquid storax known in Europe is obtained from it, and it does not grow near the localities whence liquid storax has so long been obtained. It is therefore probable that some portion is obtained by boiling the branches of *Styrax officinale*, or acting upon them with oil, spirit, or naphtha. The subject is interesting as connected with ancient commerce, inasmuch as old writers mention a liquid with the solid storax. By the Arabs the former is described under the name Mia-Saileh, liquid storax; and the latter, Mia-Yabseh, solid storax. Both are described by Serapion under the head Miha; by Avicenna under the several heads of Lubnee, Astaruk, and Miha. The name Mia-Saileh, with the affix 'rus' (juice), would appear to be the origin of the Malayan Rasamola, and thus one which has been variously corrupted.—*Eng. Cyc.* Mr. Mason writes on this tree as follows: Liquid amber. [Extracted from an article communicated by that author, in the Journal of the Asiatic Society for June 1848.] "Did you ever see in this country the tree which produces the balsam of Tolu?" a gentleman once asked me. "No," I replied, "I never did." "I have one in my compound," he continued; but unfortunately his compound was two hundred miles distant. Years passed away, and I found myself beneath this tree in flower, and soon discovered that it was not *Myrospermum toluiferum*, but *Liquidamber altingia*; and that it produced not balsam of Tolu, but liquid storax. The tree is indigenous on the Coast, and in some sections is quite abundant. A considerable stream in the province of Mergui derives its name from this tree, in consequence of its growing so thick on its banks. It seems to have escaped the notice of Dr. Helfer,

for, if I recollect right, it is not once alluded to in any of his reports, nor has it ever been brought to notice by any one; if we except a Catholic Clergyman, a resident of Rangoon, who has introduced it in a little Burmese medical treatise, that was lithographed a few years ago by Col. Burney, who took a lithographic press with him into Burmah. This gentleman, however, seems to have mistaken the tree, for he describes it as the one that produces the balsam of Peru, *Myrospermum perniferum*, and which belongs to a different natural family. The medicinal properties of their exudations too, are materially different. Liquid storax, the production of this tree, is described by Lindley, merely as "a stimulating expectorant substance—influencing the mucus membranes, especially that which lines the air passages." The writer of the Burmese medical treatise recommends the exudation of the tree for the usual purposes to which the balsam of Peru is applied, under the illusion that it is the same substance. —*Mason.*

(4956) LIQUIDAMBAR CERASIFOLIA OF WALLICH (Sedgwickia cerasifolia of Griffiths) grows in Assam, but it is not known if it yields any balsam.

(4957) LIQUIDAMBAR ORIENTALIS, is a small tree, a native of Cyprus and other parts of the East Indies; was introduced into the Jardin-des Plantes, Paris, from Smyrna, and is said to occur along the Red Sea. Dr. Pococke, as quoted by Dr. Lindley, states that it is called Xylon Effendi (the Wood of our Lord), in Cyprus, where it produces an excellent white turpentine, especially by incisions made in the bark. It is this substance perhaps which is alluded to in many works by the name Rosa malla or mallos, described as a balsamic fluid produced upon the island of Cabross, at the upper end of the Red Sea near Cadess, which is three days' journey from Suez. But there are no recent accounts of this substance, which is thought by some authors to be procured from the following species.—*Eng. Cyc.*

(4958) LIQUIDAMBAR STYRACIFLUA, is the species found in Mexico and the United States, in the latter of which it is called Sweet Gum, and forms a large and fine tree, bearing some resemblance to the lesser maple (*Acer campestre*): the wood is of a hard texture and fine grain, and makes handsome furniture, but the tree is more noted for the fragrant liquid resin which exudes from incisions in the stem, though not very copiously. This is called Liquidambar, Oil of Liquidambar, and Copalm Balsam, which has a pleasant balsamic odour, and an aromatic bitter taste. This becoming dry and opaque, forms what is called Soft or White Liquidambar, which resembles very thick turpentine, has a feebler odour than the liquid balsam, and contains less volatile oil, but more benzoic acid.—*Eng. Cyc.*

(4959) LIQUORICE. The plant which yields the liquorice root of commerce is *Glycirrhiza glabra* or *Liquiritia officinalis*. It is a native of Italy and the southern parts of Europe, but has been occasionally cultivated with success in Britain, especially at Pontefract, in Yorkshire, and at Mitcham, in Surrey. The plant is a perennial, with pale blue flowers. It grows well in a deep, light, sandy loam, and is readily increased by slips from the roots with eyes. The root, which is the only valuable part, is long, slender, fibrous, of a yellow color, and when grown in England is fit for use at the end of three years. The sweet, sub-acid, mucilaginous juice is much esteemed as a pectoral. It owes its sweetness to a peculiar principle called glycrin or glycirrhiza, which appears also to be present in the roots and leaves of other papilionaceous plants, as *G. echinata* and *glandulifera*, *Trifolium alpinum*, and the wild liquorice of the West Indies, *Abrus precatorius*, a pretty climber. The greatest portion of our supplies of the extract, which amount to 7,000 or 8,000 cwts. a year, are obtained from Spain and Sicily. The juice, obtained by crushing the roots in a mill, and subjecting them to the press, is slowly boiled, till it becomes of a proper consistency, when it is formed into rolls of a considerable thickness, which are usually covered with bay leaves. It is afterwards usually re-dissolved, purified, and, when formed into small quills, is known as refined liquorice. In 1839, 1,166 tons of liquorice paste were exported from Naples, valued at £45 per ton. Mr. Poole, in his Statistics of Commerce, states that the consumption of liquorice root and paste in this country averages 500 tons per annum. 110 cwt. of the juice and 100 cwt. of the root are annually brought into Hull from the continent.—*Simmonds.*

(4960) LIQUORICE. GLYCYRRHIZA GLABRA. Dried liquorice is found among native drugs, of Tenasserim, but Mr. Mason has never seen the plant growing.—*Mason.*

(4961) LIQUORICE JUICE, SPANISH JUICE.

Arak Soos, ARAB.	Sugo di regolizia, IT.
Jettimad-ka-rus, GUZ. HIND.	Regaliz en bollos opastillas, SP.

Is the inspissated juice of the fresh roots of the liquorice tree. It should be quite black, brittle, and break with a smooth glossy fracture; have a sweet taste, and be almost entirely soluble in water. The best description is the Spanish Liquorice. An inferior kind, in rolls about the thickness of the little finger, is imported into Bombay from the Persian Gulf.—*Faulkner.*

(4962) LIQUORICE LOZENGES, EXTRACT OF LIQUORICE, or of goonch, gum arabic, each six ounces, pure sugar one pound. Dissolve in boiling water, and concentrate to a proper consistence. *Use.*—Demulcent in irritating coughs.—*Beng. Phar. p.* 435.

(4963) LIQUORICE ROOT.

Ussulsoos, Arab.	Uratmanis, Mal.
Wellmie, Olinde, Cing.	Bikh-meeth, Pers.
Bois de reglisse, Fr.	Pao doci, Port.
Sussholz, Ger.	Madhuka, Yashtimadhuka, Sans.
Jettimud, Guz. Hind.	Regaliz Orozuz, Sp.
Legorizia, It.	Addimodaum, Tam.
Oyotmaus, Jav.	

The roots of a perennial plant (*Glycyrrhiza glabra*), a native of the South of Europe, and Persia, but cultivated in some parts of England. They are very long, about an inch thick, flexible, fibrous, of a brown colour, and when fresh, juicy; taste sweet. They are apt to spoil, and it is necessary to pack them in sand, when not required for immediate use. They are an article of the *Materia Medica*, particularly in coughs, colds, &c., and are also in demand by brewers and druggists. Liquorice root is imported into Bombay from the Persian Gulf.—*Faulkner.*

(4964) LIQUORICE PLANT OF INDIA. Abrus Precatorius.

(4965) LIQUORICE OF TENASSERIM. Acacia. Wild Liquorice of Tenasserim. There is an indigenous plant in the forests, the bark of whose roots have the taste of liquorice, but it does not belong to the same genus, though often supposed to be the same tree. I have not seen the flower, but the leaf and fruit would indicate it to be a species of Acacia.—*Mason.*

(4966) LIRIODENDRON. Magnoliaceæ. The tulip tree. This tree is highly ornamental growing to a large size and well adapted for a plantation or lining an avenue, the flowers are large and of a yellow and red color which appear in the rains, it is easily raised from seed. The bark is a strong tonic and is said to be equal to the Peruvian. The wood is fine grained and smooth, used by Coach makers and carpenters. —*Riddell.*

(4967) LISIANTHUS. Gentianeæ. Lisianthus Russellianus. This is a handsome plant, with purple flowers, the other species are white and yellow, the seed should be sown in a light vegetable mould, in pots, and transplanted when about three inches high, the flowers are large and handsome and continue perfect for many days.—*Riddell.*

(4968) LITCHI, or LEECHEE, a fruit commonly sold in the markets of China, and occasionally brought to England. It is the produce of the *Euphoria* (*Nephelium*) *Litchi* of botanists, a tree belonging to the natural order *Sapindaceæ*. The eatable part is a pulpy flesh, which covers a stone inclosed in a hard dry tesselated prickly pericarp. The Rambutan and another fruit, called the Long yen, or Longan, are yielded by species of the same genus. The Chinese cultivate many varieties of each.—*Eng. Cyc.* The lichi, originally from China, is a favourite fruit in Bengal, but did not succeed on the Tenasserim Coast until recently.—*Mason.* See Leechee.

(4969) LITHARGE.

Gelit, Dut.	Lithargyrium, Lat.
Litharge, Fr.	Murdarsang, Pers.
Glotte Glattee, Ger.	Glet, Rus.
Murdarsang, Boodar. Hind, Guz.	Almartaga, Sp.
Litargirio. It.	Marudarsinghie, Tam.

A semi-vitrified oxide of lead, in the form of small shining heavy scales, or more or less agglutinated masses. It is usually produced in the purification of silver from lead, and the refining of gold and silver by means of this metal. According to the degree of fire and state of oxidation, it has a pale or a deep colour. The one is called litharge of silver, and the other litharge of gold. Litharge is used for various purposes in the arts, by potters, glassmakers, painters, &c., it is also employed in medicine. Crude litharge is procurable in most Indian bazars.—*Faulkner.*

(4970) LITHOSPERMUM OFFICINALE. The seeds are long, very white, and like small stones or pearls, on which account they have been popularly used as a remedy for stone. They are known in India by the name of Lubisfirmun. (*Royle.*)—*O'Shaughnessy, p.* 497. The roots of some species of Lithospermum afford a lac for dyeing and painting.—*Cyc. of India.*

(4971) LITMUS.

Tournesol, Fr.	Lackmus, Ger.

A violet-blue dye, prepared chiefly in Holland from a lichen (*Lecanora tartarea*), which grows in the Canary and Cape de Verde Islands. It is met with in small cubical cakes, of a dusky blue colour, light, and easily pulverized. It is employed to stain marble; also as a chemical test of acidity, being reddened by acids, while the blue is restored by alkalis; for this purpose it is employed either in the form of a tincture, or of unsized paper coloured with it.—*Waterston.*—*Faulkner.*

(4972) LIVISTONIA, a genus of palms, natives of Eastern Asia and Australia of noble aspect and elegant foliage. The L. Jenkinsiana Griff., furnishes the "Toko-pat" of the Assamese, an indispensable article in every native gentlemans house; The leaves are in universal use throughout Assam for covering the tops of the peculiar umbrella-hats (*Jhapees*) of the Assamese, the tree does not occur in a truly wild state, and in some parts they are rare, and then of great value.—*Seeman.* There is large stately palm very abundant in the Karen jungles, the leaves of which the Karens use for thatch. In some sections of the country the Karens thatch their houses with large palmated leaves of a tall wild palm, probably a specie of livistonia: sometimes the leaves of a species of rattan are used; but the Burmese and Europeans almost univer-

sally thatch their houses with the leaves of the Nipa.—*Mason.*

(4973) LLAMA, (*Auchenia* of Illiger; *Lama* of Cuvier and others,) the generic name for that form of the *Camelidæ* which is confined to the New World. Dentition:—

$$\text{Incisors, } \frac{2}{6}; \text{ Canines, } \frac{1-1}{1-1}; \text{ Molars, } \frac{5-5}{4-4} = 30.$$

The difference between the dentition of the two sub-families of *Camelidæ*, *Camelus* and *Auchenia*, appears to consist mainly in the absence of the two small pointed teeth, which are found in the interval or 'bar' between the canines and the molars in the Camels, from the jaws of the Llamas. Thus the Llamas have four false molars, as they may be termed, less than the Camels. In other respects the dentition of the one is, as nearly as may be, the dentition of the other. The difference was considered by F. Cuvier to be of such small importance that he has not considered it necessary to give a figure of the dentition of *Auchenia*. We need not here repeat those uses to which these animals have been applied by man. Cords and scales, as well as stuffs for ponchos, &c., are fabricated from the wool, and the establishments for their manufacture in England employ thousands of artisans. In Mexico the bones are converted into instruments for weaving the wool. Nor is even the dung neglected, for it is used as fuel. These animals seem to have been to the aborigines what the reindeer (with the exception of the milk) is to the Laplander. Surrounded by herds of such animals which required almost no care, and by the spontaneous productions of the soil, the Indian had no incentive to improvement. Humboldt has an eloquent passage on this subject. "When we attentively examine this wild part of America, we seem to be carried back to the first ages when the earth was peopled step by step; we appear to assist at the birth of human societies. In the Old World, we behold the pastoral life prepare a people of huntsmen for the agricultural life. In the New World, we look in vain for these progressive developments of civilisation, these moments of repose, these resting-places in the life of the people. Those species of ruminating animals which constitute the riches of the people of the Old World are wanting in the New. The bison and musk-ox have not yet been reduced to the domestic state; the enormous multiplication of the Llama and the Guanaco have not produced in the natives the habits of the pastoral life." These multitudes are already lessened, and the form itself will probably ere long be extinct. Civilisation has brought with it the animals of the Old Continent. The horse and the mule have mostly entirely superseded the Llamas as beasts of burden, and the sheep and the goat, in a great measure, as contributors to the food and raiment of man.—*Eng. Cyc.*

(4974) LOADSTONE, MAGNET. Native Landstone. Oxydulous Iron.

Magneet, DUT.	Ahansubah, PERS.
Aimant, FR.	Magnit, RUS.
Magnet, GER.	Muzere meknates, ka-
Chumuk-Puttur, GUZ.	untum, SANS. TEL.
HIND.	Iman, SP.
Calamita, IT.	Kaundum, TAM.
Magnes, LAT.	

A combination of the protoxide and peroxide of iron. It is found in considerable quantities in Germany, Sweden, Norway, Spain, Italy, India, China, and other places.—*Faulkner.*

(4975) LOASA, LOASACEÆ. This is an interesting genus of plants, some of the species possessing the properties of nettles, the flowers are red, white and yellow, they are grown from seed, and any common soil suits them.—*Riddell.*

(4976) LOBAN, STYRAX BENZOIN: GUM BENJAMIN. Imported Via Pali: used as a stimulant, and eaten in pawn leaves; the "attars" sublime the benzoin acid very purely, and administer it as an aphrodisiac: one seer costs from two rupees to two and a half. The gum resin of the Boswellia thurifera is also considered as "luban" by the community.—*Gent. Med. Top. p.* 144.

(4977) LOBELIA. LOBELIACEÆ. This is an interesting genus of plants, easily cultivated in Southern Asia by seed, the blossoms are extremely beautiful from their variety of colours, they require a light rich soil, with a moderate quantity of water.—*Riddell.* Dr. Wight in Icones gives Lobelia aromatica, 1172; excelsa, 1172-3-4; gives *nicotianæfolia*, 1172; trichandra, 1171; trigona, 1170.

(4978) LOBELIA CARDINALIS. An annual creeping glabrous plant, a native of China. Flowers of a pink colour. In gardens it spreads over the soil, rooting at every branch, and is well adapted for borders to parterres.—*Riddell.*

(4979) LOBELIA ERINUS, and varieties.—Pretty little procumbent plants, generally having blue flowers, succeed well in the flower beds, raised from seeds. Will not live through the hot weather.—*Jaffrey.*

(4980) LOBELIA INFLATA, INDIAN TOBACCO. A native of the United States; an acrid narcotic, and violent emetic; in small doses diaphoretic and expectorant. A popular remedy in the United States, where from incautious use it has often proved fatal. Its chief employment is in asthma, and in the form of enema in strangulated hernia.—*OShaughnessy, page* 423.

(4981) LOBELIA NICOTIANIFOLIA.—Erect, leaves sub-sessile, lanceolar, acute, entire, raceme terminal. A stout tall species, occurring in the vicinity of Bangalore.—*O'Shaughnessy, page* 424.

(4982) LOBELIA RADICANS. Acciden-

tally introduced from China into the Calcutta Garden, where it flowers during the rains; small, much branched, spreading over the ground, and sending forth roots from each branchlet. Dr. O'Shaughnessy instituted numerous experiments with this species, but found it to be altogether inert.—*O'Shaughnessy, page* 425.

(4983) LOBELIA TRIGONA: A small annual ramous plant which delights in wet pasture ground, and flowers during the wet and cold seasons.—*O'Shaughnessy, page* 426.

(4984) LOCK.

Sloten. Dut.	Serrature, It
Serrures, Fr.	Kufl, Pers.
Schlosser, Ger.	Fechaduras, Port.
Tala, Kufl, Kulf, Guz. Hind.	Samki, Rus.
	Cerraduras, Cerrajos, Sp.

Well known instruments, of which there are a great variety. In England they are principally manufactured at Wolverhampton in Staffordshire, Birmingham, and London. In India, locks of an inferior description are made at Surat, chiefly in imitation of English ones.—*Faulkner.*

(4985) LOCUSTS, the principal genera contained in the family *Locustidæ* are the following:—*Locusta* (Leach), in which the hinder legs are about equal to the whole body in length, and the antennæ filiform or terminated in a club. Upwards of twenty species of this genus are enumerated by Mr. Stephens in his 'Catalogue of British Insects,' and it is to this group that the *Gryllus migratorius* of Linnæus belongs, a large species which has occasionally been found in Britain, and which in some parts of Europe sometimes multiplies to such a degree as to devastate large districts. Africa at all times appears to have been peculiarly subject to the ravages of these insects. Of their extraordinary devastations in this portion of the globe we have records from the earliest authors, and the works of the most recent travellers confirm them. Mr. Barrow in his 'Travels' states, that "in the southern parts of Africa an area of nearly two thousand square miles might be said literally to be covered with them. When driven into the sea by a north-west wind they formed upon the shore for fifty miles a bank three or four feet high, and when the wind was south-east the stench was so powerful as to be smelt at the distance of 150 miles." In Messrs. Kirby and Spence's 'Introduction to Entomology' numerous accounts of a similar nature will be found. In some parts of Africa they are cooked and eaten by the natives. The natives of Senegal are said to dry them, and, having reduced them to powder, use them as flour.—*Eng. Cyc.*

(4986) LODOICEA. DOUBLE COCOA-NUT. The Double Cocoa-nut of the Seychelles or Mahe islands, is the fruit of the Lodoicea Palm. When preserved whole, and perforated in one or two places, the nut serves to carry water, and some of them hold six or eight pints; and by slicing them in different directions, they are formed into plates, dishes, drinking cups &c. known in the Islands as Vaisselle de l' isle Praslen. The crown of the trunk is eaten like the American cabbage palm. The down attached to the young leaves serves for filling mattresses and pillows; the ribs of the canes and fibres of the petiole are fabricated into baskets and brooms, and the young canes are plaited to form hats. The Lodoicea attains a height of eighty or ninety feet. It might be introduced into India with advantage. Germinating nuts were sold in London in 1854 for £10 a piece.—*Seeman.*

(4987) LOGWOOD.

Bois de Campeche, Fr.	Campeggio, It.
Blauholz, Ger.	Palo de Campeche, Sp.

A dyewood, hard, heavy, of a deep orange colour, a sweetish astringent taste, and peculiar odour. Logwood is extensively employed for compound colours, but its chief use is for blacks, and certain shades of gray; an extract from it is also used in medicine.—*Faulkner.* The logwood of commerce is the red heart wood, or duramen, of a fine lofty growing tree (*Hæmatoxylon campechianum*), growing in Campeachy and the bay of Honduras, which is also now common in the woods of Jamaica and St. Domingo, and has been introduced into India. It is principally imported as a dye wood, cut into short lengths. We chip, grind, and pack it into casks and bags, ready for the dyers, hatters, and printers' use, who esteem it as affording the most durable deep red and black dyes. It is sometimes used in medicine as an astringent. That grown in Jamaica is least valued; that of Honduras, Tobiasco, and St. Domingo, fetches a somewhat higher price; but that imported from Campeachy direct, is the most esteemed. The annual imports into Liverpool are about 1,300 tons from Honduras, 1000 from Tobiasco, and 1,800 from Compeachy.—*Simmonds.* Logwood, is scarcely used for turning, and is a dark purple-red dyewood, that is consumed in large quantities: *Tredgold.* In Tenasserim, the log-wood tree is cultivated in a few gardens, and appears to flourish as well as an indigenous plant.—*Mason.*

(4988) LOMARIA SCANDENS. Scandent Lomaria. The low lands near the mouths of rivers and nullahs, in Tenasserim, are often fantastically dressed with a species of lomaria which creeps up to the tops of the tallest trees.—*Mason.*

(4989) LONCHURA, a genus of *Fringillidæ*, separated from *Fringilla* (Temm.) by Lieut.-Colonel Sykes. The bill is strong, short, broad; mandibles entire, the upper one extending in an angle on the forehead, and with it forming the arc of a circle. Wings moderate, subacuminate; first quill very short and subspurious; the second,

third, and fourth nearly equal and longest. Tail graduated; lanceolate; middle tail-feathers a little exceeding the others in length. Feet moderate, rather slender. Colonel Sykes observes that the peculiar spear-head form of the tail, and the ridge of the upper mandible and the forehead, forming a segment of the same circle, together with the habits of *Lonchura nisoria*, *L. Cheet*, and *L. leuconota*, afford sufficient characteristics for their separation. Colonel Sykes adds that the Gros-Bec Longicone of the Pl. Col. 96 *Emberiza quadricolor*, Lath.), belongs to the same group. The three species are found in the Deccan. The first two are recorded as found only in the Ghauts.—*Eng. Cyc.*

(4990) LONCHURA CHEET, (Sykes) is described as of a pale cinnamon-brown; the body below and the rump white; quills and tail-feathers deep brown. Irides deep red-brown. Female with the colours less intense. Length of the body $3\frac{3}{4}$ inches: of the tail 2 inches. Colonel Sykes states that these birds live in small families, and that he frequently found them in possession of the deserted nests of the *Plocens Philippensis*; their own nest, which he exhibited on a subsequent occasion, is a perfect hollow ball, made of a delicate Agrostis, with a lateral hole for the entrance of the birds. It was found in the fork of a branch of the *Mimosa Arabica*, and contained ten oblong minute white eggs, not much larger than peas, being $\frac{13}{20}$ths of an inch long by $\frac{9}{20}$ths in diameter. The cry of the bird is 'cheet, cheet, cheet,' uttered simultaneously by flocks in flight. ('Zool. Proc.')—*Eng. Cyc.*

(4991) LONICERA LESCHENAULTII. CAPRIFOLIACEÆ.

Moullee-quedi, TAM.

A twining villous shrub native of the Neilgherries, is found in many gardens of the Deccan where it grows in great luxuriance, it is easily propagated by cuttings or layers.—*Jaffrey.* Wight gives Lonicera (X.) ligustrina, 1025.

(4992) LONG PEPPER.

Dar-Filfil. ARAB.	Piper Longum, LAT.
Tipili, CYNG.	Tabee, MAL.
Poivre long FR.	Filfill-i-daraz, PERS.
Lange Pfeffer, GER.	Pippali Krishna, SANS.
Pepeelee, GUZ. HIND.	Pimenta larga, SP.
Pepe lungo, IT.	Tipili, TAM.
Chabi jawa, JAV.	Pipuloo TEL.

This species of pepper is the produce of a perennial plant (*Piper longum*), a native of Bengal, Siam &c. The fruit is hottest in its immature state, and is therefore gathered whilst green, and dried in the sun. It is met with in entire spikes about an inch long, possessing a darkish brown, or gray colour. It has a weak aromatic odour, an intensely fiery, and pungent taste, and its properties correspond closely with those of black pepper.—*Faulkner.*

(4993) LOONAR LAKE, in the circar of Meinker Soubah of Berar, about 45 miles N. W. of Hingolie, in Lat. 20° N. is at the bottom of a crater like depression, about 510 feet below the level of the surrounding country, and is 3 miles in circumference with a depth varying from 5 feet to 14, according to the season of the year. The lake presents a still sheet of water, emitting an intolerable stench of Sulphuretted Hydrogen, which, especially during the heat of the day, rises in millions of bubbles to the surface. Near the centre are two saline springs, containing muriate of soda, the water of which coming in contact with earthy carbonates in solution, a deposit takes place of carbonate of Soda or Natron Salt, in greater or less purity. The deposit is raised by diving, the purest being found close to the springs and the following are the names of the principal varieties. 1, Dulla, carbonate of Soda containing 83·8 per cent of Soda. 2. Nimuck Dulla, Nearly pure salt, containing 92·8 per cent of chloride of Sodium. Dulla, and Nimuck Dulla are used for dyeing silks, fixing colours, as medicine, and in the manufacture of bangles, of which there are two manufactories near the lake, where 600 or 700 are made by each man daily. 3. Khuppul, contains 72 per cent of carbonate of Soda, is used in fixing the red dyes of cloths. 4. Pappree contains 72 per cent of carbonate of Soda, is used in making bangles: in baking the cake called papur and in medicine as an antacid. 5 and 6. Bhooskee are neutral carbonates of Soda containing 29 and 27 per cent: is left as a deposit on the margin of the lake, and used in the manufacture of soap. The salt is raised by the divers, who rise with it in their hands: it is much prized and finds a ready sale in the bazar of Candesh, Nagpore and Poonah. The average quantity is 213 candies per annum valued at Rs. 608. —*Dr. G. Smith. Dr. J. E. Mayer.*

(4994) LOORY, but correctly Nuri in Malay, and Nor in Javanese, is the generic name for 'parrot." The sub-family of parrots, to which naturalists have given the name of Lorius, is not found in any island of the Archipelago west of New Guinea, nor at all in the Philippines. The loories of naturalists are, in fact, confined to New Guinea and its adjacent islands.—*Crawfurd Dict. page 222.*

(4995) LOPEZIA. ONAGRACEÆ, Lopezia Cordata.—This is a genus of pretty plants, annuals and biennials, their colours are purple and red, raised from seed, and grown in any good soil.—*Riddell.*

(4996) LOPHOSPERMUM. SCROPHULARINÆ. Lophospermum Scandens.—Beautiful climbing plants with large purple or rose coloured bell shaped flowers, this plant is of fast growth, and well adapted for covering trellis work, easily grown from seed at the commencement of the

rains, and lasts throughout the year, the soil should be rich and light.—*Riddell.* Mr. Jaffrey adds *Lophospermum Scandens* and *L. Hendersonii* are herbaceous climbing plants with pink bell flowers, raised from seeds and cuttings, require a sandy soil or they will not flower freely. Natives of Mexico.—*Jaffrey.*

(4997) LOQUAT. ERIOBOTRYA JAPONICA. Pomaceæ.

Young-ma, CHIN.

This tree is now introduced all over the Deccan, and bears fruit twice in the year. It is highly esteemed both for desert and preserves. It is a native of Japan, but grows in great perfection in New South Wales. The finest fruit is produced at the second crop, at the end of the cold season, and requires protection day and night; from birds in the former, and flying foxes in the latter. The fruit is a yellow color, with thin skin, a sweet acid pulp, one or two seeds in the centre—sometimes more. The seeds grow easily. Proper attention does not seem to have been given to this fruit, as it appears to be capable of great improvement.—*Riddell.* In Ajmere, it is cultivated in gardens but does not thrive well.—*Gen. Med. Top. p.* 195. It is very common in China and is often mentioned by Fortune, for instance, at one place, he found, (*Eriobotrya japonica*), the loquat or young-mai, (*Myrica Sp.*), peaches, plums, and oranges.—*Fortune's Tea. Districts, p.* 30; and there were other fruits—such as the loquat (*Eriobotrya japonica*), the Chinese gooseberry (*Averrhoa Carambola*), the wangpee (*Cookia punctata*), and the longan and leechee.—*Tea Districts, page* 7.

(4998) LORANTHACEÆ. 1419 Dr. Wight gives, in Icones, Loranthus amplexifolius, 30: capitellatus, 304; elasticus, 343,1063; (St.) euphorbiæ, 1063; lageniferus, 306; longiflorus, 302; loniceroides. 303; memecylifolius, 142; Neilgherrensis, 1020; tomentosus, 305,378; Wallichianus, 143.

(4999) LORANTHUS. Many of the Tenasserim trees are covered with different species of the parasitical genus loranthus, so abundant in most tropical climates; and the numerous small red flowers of one or two species in four forests are quite ornamental.—*Mason.*

(5000) LORANTHUS FALCATUS.

Wotu, CAN.

Wotu is the Canarese name of a shrub, the bark of which Dr. Buchanan tells us the Natives of Mysore sometimes use in place of Betel nut in conjunction with chunam, it tinges the saliva and mouth red.—*Ains. Mat. Med. p.* 269.

(5001) LOTA, a small metal pot, made of brass or copper or iron tinned.

(5002) LOTUL. OSTRIS WIGHTIANA.

(5003) LOTUS *of the Ancients.* The plant or plants referred to by classical authors under the name of *Lotus* is a subject which has engaged the attention of numerous commentators as well as of botanists. To the difficulty of ascertaining the identity of a plant but imperfectly described has in this case been added that of the same name having been applied to several very distinct plants. Fee, the latest author ('Flore de Virgile'), enumerates no less than eleven to which the name *Lotus* was applied; it is unnecessary here to enumerate more than the most remarkable. Of these some are herbaceous, others perennial. Among the former are the *L. sativa* and *L. sylvestris* of Dioscorides; the first, he states, is also called *L. trifolium*; it is supposed by some botanists to be *Melilotus officinalis*, and by others to be *M. cærulea*. Dr. Sibthorp has fixed upon *M. Messanensis* as the plant. The *L. sylvestris* of Dioscorides, also called L. *Libyan*, a native of Libya, and about two feet high, with leaves like those of *L. trifolium*, and fruit like that of Fenugreek, is thought to be the *Trigonella elatior* of Sibthorp, which he found in Asia Minor and in Cyprus. Both kinds are described by the Arabs under the name of Handachocha, or Hundkookee, with Garch and Thusf as other Arabic names. From the great number of similar plants of the tribe of *Loteæ*, which are employed by Asiatics as articles of diet or as medicines it is impossible, without specimens, to identify either of the above, but they are probably allied to the *Melilotus*.—*Eng. Cyc.*

(5004) LOTUS ÆGYPTICA, or the Egyptian Lotus, is no doubt one of the *Nymphæaceæ*, being described as springing up in Egypt in fields inundated by the river, with a stem like that of the Κύαμος, or Egyptian Bean (*Nelumbium speciosum*), and a white liliaceous flower, which rises out of the water at sunrise and sinks down again at its setting; a capsule like that of poppy, in which are contained seeds which the Egyptians roast and make into bread; with a root which is likewise eaten, both in a dressed and undressed state. The plant is no doubt the *Nymphæa Lotus* of botanists; but as in the most ancient monuments a blue-coloured lotus is likewise represented, there is no doubt that the Egyptians were also acquainted with the *Nymphæa cærulea*. At the present day the seeds of several Nymphæas roasted in sand are eaten by the natives of India, as are likewise the stalks and the rootstocks, which is said to have been the case with the Egyptian species. As the flowers of the *Nymphæaceæ* are so highly esteemed by the Hindoos, and notices respecting them constantly occur in their poetry and mythology it is possible that an Eastern legend may have given origin to the transformation of the nymph Lotis flying from Priapus into the 'aquatice lotos.' (Ovid, 'Metamorph.' ix. 341.) The Egyptian *Lotus* however is not so celebrated as another less-

known tree, to which exaggerated description has assigned a fruit of the most delicious kind, upon which the Lotophagi lived, and which, when strangers had once tasted, they ceased to wish to return to their native country. This is specially described as a tree, but there is no doubt that several have been confounded under this name. One is described both by Dioscorides and Pliny as a native of Italy of great size, forming excellent wood, with fruit about the size of pepper and resembling that of the cherry. This description applies very closely to the *Celtis australis*, or European Lote or Nettle-tree, which is one of the largest timber-trees of the south of Europe, with wood of considerable hardness and toughness. It produces berries about the size of small cherries, and with long stalks like them, eaten both by birds and children. This however comes far short of the character of the *Lotus* of the Lotophagi, of which the best description, according to Sprengel, is that of Polybius, who states that it was a moderate-sized thorny tree, with leaves like those of *Rhamnus*, but broader; that the fruit at first was like the white berries of myrtle, but became as large as an olive, of a reddish colour, and containing a small nut; taste sweetish, resembling that of figs or dates; and that a wine was prepared from it. That this tree was a native of Africa we know from the Lotophagi, who employed the fruit as their chief food, being a people of the African coast near the Syrtes. (Herod., iv. 177.) Arabian authors, in their translation of the works of the Greeks, give the synonyms in both languages, and we have, in the chapter of Serapion, retranslated into Latin, 'De Loto Arbore,' the name Sidr or Sidar, given as the Arabic name of the tree, and Nabach, Nibuk, or Nabk as that of its fruit. This name has been long known as that of a species of *Zizyphus*, and has been applied by botanists to one species, *Z. Napeca*. Dr. Shaw, in his 'Travels in Barbary,' figures a species of *Zizyphus*, which he calls 'Seedra Arabum, quæ et Lotus Veterum.' It is a prickly branching shrub, with fruit of the size of a wild plum, and of a sweetish taste and saffron colour. He found it sold in the markets, cattle fed with it, and a liquor drawn from it. Desfontaines also found this *Z. Lotus* on the same coast, and has fully described it. Mungo Park found a species of *Zizyphus* in the interior of Africa, which forms a large tree with yellow farinaceous berries of a delicious taste. The natives, he says, convert them into a sort of bread, by exposing them some days to the sun, and afterwards pounding them gently in a mortar until the farinaceous part is separated from the stone. This meal is then mixed with a little water and formed into cakes, which when dried in the sun resemble the sweetest gingerbread. It may be added, that the fruit of several species of *Zizyphus* is eaten in India. One kind, commonly known by the name Ber, forms a moderate-sized tree in a cultivated state, wi oval fruit of a yellowish or reddish colour, a about the size or somewhat smaller than a co mon plum, which is much esteemed. The ta is mild and sweet, with a slight degree of acidi probably coming nearer in the taste of dates th any other fruit. In Persian works Berce a Harree are given as its Hindustanee, Kinar a Khiel as its Persian, and Sidr as its Arabic nam with Nebbe for the fruit. The fruit of the wi kind is dried and powdered, as was done wi the *Lotus* of the Lotophagi. This powder, Arabic, is called Savikoon-Nebbek; in Persia Arud-i-Kinar; and in Hindoo, Ber-Choonee.—*Eng. Cyc.*

(5005) LOUGH DIVER, a name for *Merg albellus*.

(5006) LOVE-APPLE, OR TOMATO. T produce of South America and of a genus of t same family as potatoes. There are two sorts, si gle and double: they may be sown immediat the rains commence, in beds; afterwards tra planted in rows, two feet apart, and trailed up sticks of a strong description. If the soil good, they will grow to seven or eight feet height. The double, which are the finest, if so in June, ripen in October. The lower branch should be pruned, and a succession of crops m be kept up until April. The small single toma with a slight protection from the dry winds, w continue until the rains.—*Jaffrey*.

(5007) LOVE LIES BLEEDING.—Amara thus.

(5008) CROSSBILL. There are many w consider the Parrot Crossbill (*Loxia pityopsitt cus*) to be merely a larger and more robust vari ty of the Common Crossbill (*L. curvirostr* By the same rule, the Himalayan Crossbill (*himalayana*) should be regarded as a smaller a considerably less robust variety of the same sp cies; in which case, the amount of variati would indeed be extraordinary, and we shou expect to find every intermediate gradation. T Crossbills, in a general way and with unimpo tant exceptions, may be said to inhabit wherev there are pine-forests; however rare, comparativ ly, in those of the Himalaya: and they are bir of remarkably vagrant habits, which therefo should not be particularly subject to climatal local influences, whatever these may be, to indu permanent variation, as manifested by a series distinct races.

(5009) LUCERN. MEDICAGO SATIVA. S GRASSES.

(5010) LUCULIA, a genus of Plants belon ing to the natural order *Cinchonaceæ*, tribe *Ci choneæ*, and sub-tribe *Eucinchoneæ*: thus ind cating the close affinity of this genus to that the trees yielding Peruvian Bark, or true Ci chonas, in which indeed the only known speci *L. gratissima* was placed by Dr. Wallich a figured in his 'Tent Fl. Nepal,' t. 21. It

found in great abundance on Nag-Urjoon and some of the other smaller hills in the valley of Nepaul; also at Bechiaco and Koolakam. It delights in exposed rather naked situations, blossoming, according to the situations where it is found, nearly the whole year round. It is also found on the Pandoon Hills in Silhet, flowering in the month of September. As seen by Dr. Wallich it attains a height of 16 feet, but he was informed of its growing to a larger size. It has been introduced into and has flowered in Great Britain; but from the nature of the climate where it is indigenous, it is only suited to the greenhouses of England. Its locality and affinity are interesting, particularly when coupled with the prevalence in the same mountains of two other genera, *Hymenodictyon* and *Hymenopogon*, belonging to the same sub-tribe *Eucinchonea*, and therefore equally allied to the true Cinchonas; all indicating the part of the Indian territory where these valuable plants might most certainly be grown, and yield a profitable article of commerce. "It is impossible to conceive anything more beautiful than this tree when covered with its numerous rounded panicles of pink-coloured very fragrant large blossoms." (Wallich.) —*Eng. Cyc.*

(5011) LUCULIA GRATISSIMA, one of England's common hot-house ornaments, grew in profusion on the dry micaceous rocks at the Tambur River in East Nepaul: its gorgeous heads of blossoms scenting the air, and *Thunbergia*, Convolvulus and other climbers, being in graceful festoons on the boughs.—*Hooker, Him. Jour. Vol. I. p.* 193.

(5012) LUCULIA PINCEANA, makes a gorgeous show in the Khasia Hills in October. —*Hooker, Him. Jour. Vol.* II. *p.* 286.

(5013) LUDWIGIA PARVIFLORA. In stagnate water, in Tenasserim, a species of ludwigia which bears a pretty flower, is quite common.—*Mason.*

(5014) LUFFA, a genus of plants belonging to the natural order *Cucurbitaceæ*. The male flowers are panicled and yellow; the tube of the calyx hemispherical, segments longer than the tube; petals distinct, dropping off by the base stamens 5, distinct; anthers very wavy. The female flowers are solitary; the tube of the calyx oblong, clavate, segments shorter than the tube; stamens abortive; stigmas reniform; gourd ovate, 3-celled, fibrous, internally operculate.—*Eng. Cyc.*

(5015) LUFFA. ACUTANGULA ANGULAR FRUITED LUFFA.

Chanlaturai. HIND. *Genl. Med. Top. p.* 209.

The leaves of *L. acutangula* are a favourite potherb of the natives of India and are esteemed very wholesome. This luffa gourd has ten sharp ridges by which it may be easily recognized, and Roxburgh says that with a little butter, pepper and salt, "it is little inferior to green peas."—*Mason.*

(5016) LUFFA AMARA. Syn. CUCUMIS INDICUS.

Kerula, HIND.

Is found in hedges and dry uncultivated places in the East Indies. It has several stems, slender, running to a great extent, but with few branches, pretty smooth, 5-sided; tendrils 3-cleft; leaves slightly 5-7-lobed, rough; stipules axillary, solitary, cordate, with glandular marks on one side. Male flowers pretty large, yellow, on long erect axillary racemes; the pedicels with a glandular bract near the base, and articulated a little above it. Female flowers rather larger axillary, solitary, pedunculated; fruit oblong, 3 or 4 inches long, and 1 inch in diameter, tapering equally towards each end, 10-angled: when ripe dry, gray, filled with dry fibres; the operculum deciduous: seeds blackish gray, with elevated minute black dots; every part is extremely bitter. The fruit is violently cathartic and emetic; the juice of the roasted young fruit is applied to the temples to cure headache by the natives of India; the ripe seeds are used either in infusion or substance by them to vomit and purge.—*Eng. Cyc.*

(5017) LUFFA BINDAAL, is a native of Hindustan. It is a climbing dioecious plant; the leaves are toothed and 5-angled. Male flowers in racemes. Female flowers solitary; fruit round, echinate, with long, straight, ciliate bristles. It is considered in northern India a powerful drastic in cases of dropsy.—(*Roxb. Fl. Ind.* iii. p. 717.)—*O'Shaughnessy, p.* 546.

(5018) LUFFA FŒTIDA.

(5019) LUFFA PENTANDRA.

Gheeaturai HIND.

Five stamined much cultivated in the rains.—*Genl. Med. Top. p.* 209. Pentandrous Luffa, is a long gourd with a striped skin, considered by the natives a delicious vegetable.

(5020) LUFFA PENTANDRA, ACUTANGULA CLAVATA, and *racemosa*, the two first called *Ghia* and *Kalee-tori*, are cultivated or found wild in all parts of India.—*O'Sh. p.* 346.

(5021) LUFFA TENERA, receives also from Royle the name of *Kalitori.—O'Shaughnessy, p.* 346.

(5022) LUPINUS. LEGUMINOSÆ. Lupinus bicolor.—These flowers blossom during the latter end of the cold season, and should never be sown until the rains are over. Some of the species are very delicate, but the small blue, white lupin, rose lupin, and Egyptian, flower freely. Some of the species are very common in Egypt, and grown for food, the seed being ground into flour. Is propagated by seed, and should be sown in pots; and if in beds, about one foot apart.

(5023) LUTRA, a genus of *Mammalia* belonging to the family *Mustelidæ*. The species are known by the common name of Otters. They form a natural group of Carnivorous Animals whose habits are acquatic and whose food is fish. The common term Otter is applied to two forms and nearly allied: the first, including the River-Otter *Lutra*, of Stoor; the second, the Sea-Otter, *Enhydra* of Fleming.

Enhydra.—Dr. Fleming gives the following generic character of the Sea-Otter under the above name:—Six incisors above, and four below. Tail much shorter than the body. No anal scent-bags. In Cook's 'Voyage' it is stated that a young Sea Otter was brought on board with six lower incisors. Steller and succeeding systematists give four as the number in the lower jaw. Sir John Richardson suggests that two of the lower ones may drop out before the animal becomes adult. The fur is thick, woolly, and very soft, with the addition of a few silky hairs of a lustrous black; most of the upper parts are of a deep velvety maroon-brown, and the anterior parts silvery-gray. Body elongated; tail short and stout; hinder feet very short.

Enhydra marina is the Sea-Beaver of Kraschenikoff the Sea-Otter of Cook, Pennant, Mears, Menzies, and Godman: the Kalan of the Kamtchatkadales; *Mustela Lutris* of Linnæus; *Lutra marina* of Steller, Erxleben, and Harlan; Loutre du Kamtchatka of the French. Captain Cook in his last voyage (chapter on King George's Sound Nootka), says: "It might have been sufficient to have mentioned that this animal (the Sea-Otter) abounds here, as it is fully described in different books, taken from the accounts of the Russian adventurers in their expeditions eastward from Kamtchatka, if there had not been a small difference in one that we saw. We for some time entertained doubts whether the many skins which the natives brought really belonged to this animal; as our only reason for being of that opinion was founded on the size, colour, and fineness of the fur; till a short while before our departure, when a whole one, that had been just killed, was purchased from some strangers who came to barter; and of this Mr. Weber made a drawing. It was rather young, weighing only 25 lbs.; of a shining or glossy black colour, but many of the hairs being tipt with white give it a grayish cast at first sight. The face, throat, and breast were of a yellowish-white or very light brown colour, which in many of the skins extended the whole length of the belly. It had six cutting teeth in each jaw; two of those of the lower jaw being very minute, and placed without, at the base of the two middle ones. In these circumstances it seems to disagree with those found by the Russians, and also in not having the outer toes of the hind feet skirted by a membrane. There seemed also to be a greater variety in the colour of the skins than is mentioned by the describers of the Russian Sea-Otters. These changes of colour certainly take place at the different gradations of life. The very young ones had brown hair, which was coarse, with very little fur underneath; but those of the size of the entire animal which came into our possession, and just described, has a considerable quantity of that substance; and both in that colour and state the Sea-Otters seem to remain till they have attained their full growth. After that they lose the black colour, and assume a deep brown or sooty colour; but have then a greater quantity of very fine fur, and scarcely any long hairs. Others, which are suspected to be still older, were of a chestnut brown; and a few skins were seen that had even acquired a perfectly yellow colour. The fur of these animals, as mentioned in the Russian accounts, is certainly softer and finer than that of any others we know of; and therefore the discovery of this part of the continent of North America, where so valuable an article of commerce may be met with cannot be matter of indifference." The Sea-Otter haunts sea-washed rocks, lives mostly in the water, and approximates to the seals more than to the otters in its habits. The food is fish. The female brings forth on land, and notwithstanding the general marine habits of the animal it has been occasionally seen very far from the shore. It is found in the North Pacific, from Kamtchatka to the yellow Sea on the Asiatic side, and from Alaska to California on the American coast. (Richardson.) The fur was eagerly sought after, and is still prized, but not so highly as formerly. Coxe quotes Pallas for the fact that the old and middle-aged sea-otter skins were sold at Kiachta by the Russians to the Chinese at from 80 to 105 roubles a skin, or from 16*l*. to 20*l*. each. Sir John Richardson obsrves that the trade was for a considerable period in the hands of the Russians, who, soon after the discovery of the north-west coast of America by Behrin and Tschirikow, sent mercantile expeditions there. The passage above quoted from Captain Cook's 'Third Voyage' drew the attention of the English, and both private merchants and the India Company sent vessels to collect skins on the American coast and transport them to Canton. Pennant's hint at the profitable trade which might be carried on with China by a colony, were it possible to penetrate to that part of America by means of rivers and lakes, seems not to have been lost. Sir Alexander Mackenzie having traversed the continent of America and reached the Pacific, his partners in trade established fur ports in new Caledonia and a direct commerce with China; but, as Sir John Richardson remarks in conclusion, the influx of furs into that market soon reduced their price.

(5024) LUSTRICOLA. [PTILONIDÆ.]

(5025) LUTRARIA. [PTILONIDÆ.]

(5026) LUZULA, a genus of Plants belonging to the natural order *Juncaceæ*. It has a 1-celled 3-valved capsule, without dissepiments, with three seeds at the base of the cell. Several species of this genus have been described.

(5027) LUZULA CAMPESTRIS, has a panicle of 3 or 4 ovate, dense, sessile, or stalked clusters; filaments much shorter than the anthers; seeds nearly globular, with a basil appendage. The root of this species has a popular reputation as a diuretic, and is used in China and the north of Europe.—*Eng. Cyc.*

(5028) LYCHAIS CORSICA. There are three sorts—scarlet, white and fulgens. The first is an extremely showy flower, and ornamental either in a border or pot. It seldom exceeds eighteen inches in height, and after flowering, if cut down, will shoot out and blossom again. The seed should be sown either in or after the rains,—moderate care is all that is necessary.—*Riddell.*

(5029) LYCHNIS (from λύχνος, a lamp), a genus of Plants belonging to the natural order *Caryophyllaceæ*, and to the sub-order *Sileneæ*. It has a 5-toothed naked calyx; 5 petals, clawed; 10 stamens; 5 styles; the capsules 1 celled, or half 5-celled, opening at the top with 5 or 10 teeth. The species are smooth, hairy, or woolly herbs, with terminal corymbs of flowers, rarely solitary.—*Eng. Cyc.*

(5030) LYCHNIS CHALCEDONICA, the Scarlet Lychnis, is a smoothish clammy plant, with corymbose flowers in bundles; the calyx cylindrical, clavate, ribbed; the calyx 2-lobed, the carpophore long; the leaves lanceolate, slightly cordate at the base, and clasping the stem. This plant, which produces scarlet, rose-coloured, or white flowers, and is a great favourite in gardens, is a native of Siberia and Japan. Several varieties of this plant have been named.—*Eng. Cyc.*

(5031) LYCHNIS GRANDIFLORA is a glabrous plant, the flowers solitary or ternate, terminal and axilliary; the calyx terete, clavate, ribbed; the petals lacerated; carpophore elongated: the leaves ovate, almost sessile. It has large beautiful scarlet flowers, and is a native of China and Japan.—*Eng. Cyc.*

(5032) LYCIUM, a genus of Plants belonging to the natural order *Solanaceæ*. It has an urceolate calyx regularly 5-toothed, or irregularly 3-5-cleft; permanent corolla funnel-shaped or tubular; limb 5- or 10-cleft, or toothed, imbricate in æstivation, sometimes plicate; stamens 5, usually exserted; filaments bearded and widened at the base; stigma peltately depressed, or capitate, bisulcate; berry roundish, 2-celled, propped by the permanent calyx; placentas adnate; seeds numerous, reniform. The species are trees or shrubs usually spinose. Corollas white, yellow, rose-coloured, purple, blue or scarlet. Dr. Wight, in *Icones*, gives Lycium Afrum, 1402; Europeum, 1403; Indicum, 1403 Ruthenicum, 1403. There are about 30 species of this genus described, many of which are to be found in gardens. They are commonly known by the name of Box-Thorn. Many ancient authors, and among others Dioscorides describe under the above name a substance as used in medicine which is stated to be of two kinds; one obtained from Lycia and Cappadocia, and the other from India. The former is said to be the produce of a thorny shrub called *Pyxacantha*. The latter is stated to be more valuable and efficacious as a medicine, and to be produced also by a thorny shrub which is called *Lonchitis*. Most modern authors have stated these plants and the substance they produce to be totally unknown; others consider species of *Rhamnus*, or the common Box, to be alluded to. Prosper Alpinus thought *Berberis Cretica* to be one of the plants; while Garcias ab Orto thought Catechu to be the substance, and *Acacia Catechu* the plant yielding it. It is possible that some species of *Rhamnus*, as *R. infectorius*, of which both the root, wood, and berries possess medicinal properties, and which are in the present day used for dyeing yellow, may have formed one of the kinds of Lycium, as it is common in the countries where the first kind is said to have been produced, and some species of *Rhamnus* were by the older botanists called *Lycium*. Though there is uncertainty about the Lycium of Asia Minor, that of India seemed to have been quite unknown until the publication of a paper 'On the Lycium of Dioscorides,' by Dr. Royle, in the 'Linnæan Society's Transactions' for 1833, where it is stated that there is no proof that Catechu was the Ἄνκιον, Ινδικόν, (*Lycium Indicum*) of the ancients; in fact is incompatible with the evidence adduced on the subject from Oriental writers. The Greek authors on medicine having been translated into Arabic, and from this language into Persian, and these, with additions, forming the works now in use in India, we may expect to find in them some trace of Lycium; and in fact in that called Makhzun-al-Udwieh, Loofyon is mentioned as the plant which yields Huziz, and in Persian it is called Feel-Zuhreh. Loofyon is evidently written for Lookyon, through an error of the transcriber in a diacritical point, in the same way that Filafoos (Philip of Macedon) has been changed in some of these work into Filakoos. This is further evident indeed from referring to the Latin translations of Serapion and Avicenna, where Haded and Feel Zuhuruj are translated *Lycium* and *Lycium Indicum*. In the Persian work, Hoozuz or Hooziz (the same word as Hadad) is described as being of two kinds: one from India, of which the Hindoo name is Rasot; and the other from Arabia. The Persian name Feel-Zuhreh is translated in our best dictionaries 'box thorn,' that is, *Pyxacantha*. The best kind of

Rusot is said, in the Makhzun-ul-Udwieh, to be brought from Nuggur Kote in the neighbourhood of Lahore, and that it is an extract made from a decoction of the fresh wood of Dar-Huld. On inquiring in the shops of the druggists in the bazars of India, Dr. R. learned that both the wood Dar Huld and the extract Rusot were imported into plains of India from the Himalayas. On travelling in these mountains, and on wishing to be shown the plant which produced the wood called Dar-Hnld as well as that from which the Rusot was procured, species of Barberry were immediately pointed out, and it was stated that both the wood and the extract were procured indifferently from *Berberis Asiatica*, *B. aristata*, *B. Lycium*, and *B. pinnata*. On cutting into the wood of each, and having some converted into extract, he found both to correspond in every respect with what he had bought in the plains under the name of Dar-Huld and Russot. The extract Russot is procurable in the bazars of India, being much employed by the native practitioners of medicine in India, as an external application rubbed over the swollen eye-lid either simply or in combination with opium and alum and a little water or oil, both in incipient and chronic inflammation of the eye. The wood of Barberry being employed both in Europe and India as a yellow dye, it has been suggested by Mr. E. Solly, in a paper read before the Royal Asiatic Society, that the root, wood, or extract might be imported from India for the use of the manufacturers of Europe. This notice may appear disproportioned to the importance of the subject, but it is interesting as showing the knowledge which the Greeks had of the products of India, at the same time that it proves the great extent to which the influence of their own works has spread.—*Eng. Cyc.*

(5033) LYCOPERSICUM. The Tomato or Love apple. The tomato or love-apple, a delicious vegetable abounds in Ava and is cultivated to a limited extent in many gardens. The produce of South America a genus of the same family as potatoes. There are two sorts, single and double; may be sown immediately the rains commence, in beds; afterwards transplanted in rows, two feet apart, and trailed upon sticks of a strong description. If the soil is good they will grow to seven or eight feet in height. The double, which are the finest, if sown in June, ripen in October. The lower branches should be pruned, and a succession of crops may be kept up until April. The small single tomato, with a slight protection from the dry winds, will continue until the rains.—*Riddell.* See Love-apple.

(5034) LYCOPODIUM. An inflammable powder used in fire works, obtained from a common moss-like plant of the same name.—*Wedderston.* Lycopodium a genus of Plants belonging to the natural order *Lycopodiaceæ*. It has 1-seeded 2 valved capsules, containing powder, or 3-valved contain.

(5035) LYCOPODIUM. Club moss. The green woods of the Tenasserim southern provinces are often carpeted with the club moss, or ground pine, of which we have one or two handsome species.—*Mason.* Mr. Fortune writes of a species as follows:—When I was travelling on the hills of Hong-Kong, a few days after my first arrival in China, I met with a most curious dwarf Lycopodium, which I dug up and carried down to Messrs. Dent's garden, where my other plants were at the time. "Hai-yah," said the old compradore, when he saw it, and was quite in raptures of delight. All the other coolies and servants gathered round the basket to admire this curious little plant I had not seen them evince so much gratification since I shewed them the "old man Cactus" (*Cereus Senilis*) which I took out from England, and presented to a Chinese nurseryman at Canton. On asking them why they prized the Lycopodium so much, they replied, in Canton English "*Oh he too muchia handsome; he grow only a leete and a leete every year; and suppose he be one hundred year onla he only so high*" holding up their hands an inch or two higher than the plant. This little plant is really very pretty, and often naturally takes the very form of a dwarf tree in miniature which is doubtless the reason of its being such a favourite with the Chinese.—*Fortune's Wanderings, page* 95.

(5036) LYCOPODIUM CLAVATUM, of the British moors; grows at Chakoong in the Lachen Lachoong valley, Sikkim, and amongst mosses, the superb Himalayan *Lyellia* crispa, with the English *Funaria hygrometrica.—Hooker. Him. Jour. Vol.* II, *page* 19.

(5037) LYELLIA CRISPA, grows at Chakoong in Sikkim, in the Lachen Lachoong valley, it is one of the most remarkable mosses in the Himalaya mountains, and derives additional interest from having been named after the late Charles. Lyell, Esquire of Kinnordy, the father of the most eminent geologist of the present day.—*Hooker, Him. Jour. Vol.* II. *p.* 19.

(5038) LYGODIUM SCANDENS. Ophioglossum. One of the most elegant climbers on the Tenasserim Coast is a terrestrial species of fern, easily recognized by its habit of running over other plants, and by the fringed margin of its leaflets, from which it is sometimes called "fringed fern." An allied species is found in the United States.—*Mason. Tavoy.*

(5039) LYMNÆA HOOKERI. The waters of the Lachen in Tibet contained many shells of a species of Lymnæa. This is the most alpine living shell in the world, many specimens being from nearly 17,000 feet elevation; it is the *Lymnæa Hookeri*, Reeve ("Proceedings of the Zoo-

logical Society." No. 204).—*Hooker, Him. Jour. Vol.* II. *page* 156.

(5040) LYTHRAM HUNTERI. Hunter's Loosestrife, is a native of the East Indies. The leaves are opposite, the calyx tabular and 6-lobed, the stamens 12, and the style subulate. The petals, 6 in number, are of a very beautiful red-colour, and are used for dyeing in India. The hardy perennial species of *Lythrum* are handsome garden-flowers; they grow in any common soil, and are easily propagated by dividing at the root. The seeds of the annual kinds require to be sown in moist situations in the spring. (Don, *Dichlamydeous Plants*; Babington, *Manual of British Botany*.)

(5041) LYTHRUM, (from λύθρον, 'black blood,' from the purple colour of the flowers), a genus of Plants belonging to the natural order *Lythroceæ*. It has a tubular cylindrical calyx, with from 8 to 12 teeth; from 4 to 6 of the teeth are broader than the rest and erect, the alternate ones being subulate and opposite to the petals. It has from 4 to 6 petals and very short style. The capsules are 2-celled and many-seeded.

(5042) LYTHRUM. LYTHRACEÆ. This is a common plant, native of Great Britain, it thrives in any common soil, and easily cultivated from seed.—*Riddell.*

M.

(5043) MACACUS, a barbarous word founded on the term Macaco (written by the French Macaque), which, according to Cuvier and the author of 'Natural History of Monkeys, Lemurs and Opossums,' appears for the first time in Marcgrave's 'Natural History of Brazil,' as the native appellation of a kind of monkey found in Congo and along the coasts of the Gulf of Guinea. Dr. J. E. Gray arranges the genus as the last of his sub-family *Cercopithecina* (family *Hominidæ*). M. Lesson, who makes the characters of the genus consist in a facial angle of from 40 to 45 degrees; in a very strong development of the supraciliary and occipital crests; the presence of pouches and callosities, and a tail more or less long, gives as its dental formula that which is common to so many of the *Simiadæ*, namely:—

$$\text{Incisors, } \frac{4}{4}; \text{ canines, } \frac{1-1}{1-1}; \text{ molars, } \frac{5-5}{5-5} = 32;$$

and he arranges under it the following species:—*Silenus, Sinicus, S. carbonarius, S. radiatus, S. cynomolgus, S. Rhesus, S. nemestrinus*, and *S. speciosus*. Sir William Jardine adopts the genus with the following species:—*Macacus Silenus, M. Sinicus, M. radiatus, M. cynomolgus, M. Rhesus, M. nemestrinus*, and *M. niger*. Reverting to the arrangement of the author of the 'Natural History of Monkeys,' &c., we find the Papios divided into two small groups, distinguished by the greater or less length of the tail on the one hand and its tuberculous form or total absence on the other; of the latter the well-known Magot, or Barbary Ape, is an example, and the Wanderoo (*Macacus Silenus* of authors, *Papio Silenus* of the author of the 'Nat. Hist. of Monkeys') is an illustration of the former. The Wanderoo has its hair deep black throughout, with the exception of the long beard or mane, which descends on each side of the face in the form of a ruff, extending downwards over the chest, and varying from an ash-gray to a pure white. The upper part of the face between the eyes naked and flesh-coloured: the muzzle perfectly black. Cheek-pouches large, callosities of considerable size, and flesh-coloured. Tail about half as long as the body, and when perfect, which in captivity is not often the case, terminating in a brush of tufted hairs. (Bennett.) It is the Lion-Tailed Baboon of Pennant. It is an inhabitant of the peninsula of India, Ceylon [Knox] M. Duvaucel saw the animal in the Menagerie at Barrackpore.—*Eng. Cyc. Vol.* III. *page* 567. The following species of *Macacus* are given in the 'British Museum Catalogue:'—

M. radiatus, the Zati, or Capped Macaque.
M. Sinicus, the Munga, or Bonnet-Macaque.
M. nemestrinus, the Bruh.
M. cynomolgus, the Macaque.
M. Rhesus, the Rhesus.
M. Oinops, the Oinops.
M. speciosus.
M. Juncus, the Magot.
M. niger.

In the same Catalogue the Wanderoo is referred to *Silenus veter*. In his 'British Fossil Mammals,' Professor Owen describes a species of *Macacus* under the title of *M. eocenus*; teeth of these extinct species having been found in the Tertiary clay at Kyson, near Woodbridge, Suffolk. The following is given by M. F. Cuvier as the dental development of the Macaques and Cynocephales, and is taken from the Chinese Bonnet-Monkey (Macaque Bonnet Chinois).

(5044) MACACUS PELOPS, HODGSON. On arriving at Lamteng, in Sikkim, Dr. Hooker saw a troop of large monkeys gambolling in a wood of *Abies Brunoniana*: this surprised him, as he

was not prepared to find so tropical an animal associated with a vegetation typical of a boreal climate. This *Macacus Pelops*? Hodgson, is a very different species from the tropical kind seen in Nepal.—*Hooker, Him. Jour. Vol.* II. *p.* 37.

(5045) MACCARONI.

Save, Guz. Hind. | Semeean, Tam.

A wheaten paste, formed into long, slender, hollow tubes, and used in soups, &c. Maccaroni is the same substance as vermicelli, the only difference consisting in the latter being made into thinner and smaller tubes. The Indian variety is a commoner kind than either of the above, and is not in the tubular form : it is properly served up in a boiled state, mixed with milk and sugar.—*Faulkner.*

(5046) MACE.

Talzuffar, Arab.
Bunga-pala, Bali.
Wassawassie. Cyng.
Foely. Foelie, Muscaatblooin, Dut.
Fleur de muscade Fr.
Macis, Ger.
Jaiwantry. Jaiputree, Guz. Hind.

Jatipatri Sans.
Macio, Sp.
Jadiputrie, Tam
Japatri, Tel.

A thin flat branching membranous substance enveloping the nutmeg, of a lively reddish-yellow colour, a pleasant aromatic smell, and a warm bitterish pungent taste. It is the arillus of the nutmeg and is chiefly used for culinary purposes and in pickling ; it is also a favourite medicine of the Hindu physicians, who prescribed it in the slow stages of fever, &c. It is imported into India from Singapore, Batavia, and the Banda Islands. That procurable in Bombay is imported exclusively from the former place.—*Faulkner.* *Mace* is a valuable article, but wild mace is occasionally used for adulterating the true mace — *M. E. J. R. Mace* forms around the shell of the nutmeg a fleshy, branching, and when recent, bright, scarlet covering but in the process of drying it changes to yellow, orange yellow, or what is considered best, golden yellow, and becomes transparent and horny. It is prepared by drying in the sun for some days. The aril is sometimes flattened out, and dried in a single layer, but frequently it is pressed together, in which case it forms two layers. The Dutch sprinkle mace with salt water prior to packing it in sacks. As there are two kinds of nutmegs, so are there two kinds of mace, the produce of the same plants ; thus, there is true or cultivated mace, and false or wild mace. The London dealers distinguish three sorts of true mace : —

"1. *Penang Mace.*—This fetches the highest price. It is flaky and spread. The annual quantity produced in Penang is about 130 piculs (of 133⅓ lbs. each.)

"2. *Dutch or Batavian Mace.*—This is a fleshy sort. It scarcely fetches so high a price as the Penang sort.

"3. *Singapore Mace.*—This is a somewhat inferior kind.

Wild or false mace is of a dark red colour, and deficient in flavour and aroma. Viewed under the microscope, mace presents a structure very distinct from that of the nutmeg itself. Of twelve samples of mace examined by Dr. Hassall, all were genuine but much difference was observed in the quality of several of the samples. The duty on genuine mace is nearly the same as that on nutmegs, namely 2s. 6d. per pound, and five per cent. It is now 1s. per lb. Wholesale price, 2s. to 2s. 6d. ex-duty. Entered for home consumption in 1852, 21,485 lbs : in 1853, 23,558 lbs.—*Food and its adulteration, p.* 412.

(5047) MACE, FALSE.

Ramputree. Guz. Hind.

The mace of the male or false nutmeg is distinguished from the true mace by being formed of three or four regular bands united at the summit. The chemical properties of this article are analogous to that of the true mace, but the oil is so inferior in proportion, that the male mace is but of little commercial value. Owing to its comparative cheapness, false mace is used in India only among the lower orders of the natives. It is procurable in most bazars.—*Faulkner.*

(5048) MACE OIL.

Jaiwantry, or Jaiputrie-kateil, Hind. | Jaiputrie tailum, Tam. Wassa Wasitalf, Cyng.

This fixed oil is obtained by expression ; it is of a butyraceous consistence, brown colour, and highly fragrant. It is very stimulant, and is much employed as a liniment and embrocation in rheumatism.—*Faulkner.*

(5049) MACAW TREE, Acrocomia sclerocarpa, Mart. The great Macaw tree of the West Indies, belongs to a genus of palms some of which are important in commerce. The value of the Macaw Tree is chiefly owing to its fruit, which yields an oil. In the process of extraction, the fruit is slightly roasted and ground to a paste, first in a mill and then on a levigating stone. This paste, having been heated, and mixed with 3/10ths of its weight of boiling water, is put in a bag, and pressed between two heated plates of iron, it yields about 7/10ths or 8/10ths of oil. The oil, if discoloured, can be purified, when melted, by filtration. It is then of the consistence of butter, of a golden yellow hue, has an odour like violets and a sweetish taste. If well preserved it will keep several years, if spoiled, it loses its golden hue and delightful aroma. It is frequently sold in the shops as "*palm oil*" and at present enters largely into the composition of toilet soaps. It might be usefully introduced into the East Indies.—*Seeman.*

these spread the roots about two inches thick for drying in the sun. Carry the platforms to a convenient place, not far from the house, and place them side by side, in rows east and west, and with their ends north and south, leaving room to walk between the rows. Elevate the south ends of the platforms about eighteen inches, and the north ends about six inches from the ground, putting poles or sticks to support them —this will greatly facilitate drying. After the second or third day's drying, the madder must be protected from the dews at night, and from rain, by placing the platforms one upon another to a convenient height, and covering the uppermost one with board. Spread them out again in the morning, or as soon as danger is over. Five or six days of ordinarily fine weather will dry the madder sufficiently, when it may be put away till it is convenient to kiln-dry and grind it.

Kiln-drying.—The size and mode of constructing the kiln may be varied to suit circumstances. The following is a very cheap plan, and sufficient to dry one ton of roots at a time. Place four strong posts in the ground, twelve feet apart one way, and eighteen the other: the front two fourteen feet high, and the other eighteen: put girts across the bottom, middle, and top, and nail boards perpendicularly on the outside as for a common barn. The boards must be well seasoned, and all cracks or holes should be plastered or otherwise stopped up. Make a shed-roof of common boards. In the inside put upright standards about five feet apart with cross-pieces to support the scaffolding. The first cross-pieces to be four feet from the floor; the next two feet higher, and so on to the top. On these cross-pieces lay small poles, about six feet long and two inches thick, four or five inches apart. On these scaffolds the madder is to be spread nine inches thick. A floor is laid at the bottom to keep all dry and clean. When the kiln is filled, take six or eight small kettles or handfurnaces, and place them four or five feet apart on the floor (first securing it from fire with bricks or stones), and make fires in them with charcoal, being careful not to make any of the fires so large as to scorch the madder over them. A person must be in constant attendance to watch and replenish the fires. The heat will ascend through the whole, and in ten or twelve hours it will all be sufficiently dried, which is known by its becoming brittle like pipe stems.

Breaking and grinding.—Immediately after being dried, the madder must be taken to the barn and threshed with flails, or broken by machinery (a mill might easily be constructed for this purpose), so that it will feed in a common grist-mill. If it is not broken and ground immediately, it will gather dampness so as to prevent its grinding freely. Any common grist-mill can grind madder properly. When ground finely it is fit for use, and may be packed in barrels like flour for market.

Amount and value of product, &c.—Mr. Swift measured off a part of his ground, and carefully weighed the product when dried, which he found to be over two thousand pounds per acre, notwithstanding the seasons were mostly dry and unfavourable. With his present knowledge of the business, he is confident that he can obtain at least three thousand pounds per acre, which is said to be more than is often obtained in Germany. The whole amount of labor he estimates at from eighty to one hundred days' work per acre. The value of the crop, at the usual wholesale price (about fifteen cents per pound), from three to four hundred dollars. In foreign countries it is customary to make several qualities of the madder, which is done by sorting the roots; but as only one quality is required for the western market, Mr. Swift makes but one, and that is found superior to most of the imported, and finds a ready sale. Madder is produced in Middle Egypt to some extent, for the consumption of the country, principally for dyeing the *tarbouche* or skull caps which are universally worn. Its culture was introduced in 1825. In 1833 300 acres in Upper Egypt, and 500 in the Delta and the Kelyout, were devoted to madder roots. New S. Wales is eminently suited to the culture of this valuable root, and as the profits upon its cultivation are very large, it is strongly recommended to the attention of agriculturists there. The article produces to France an annual sum of one million sterling; the price of the finest quality in the English market being £60 per ton. Its yield varies from £40 to to £50 per acre, and the expenses upon its proper culture should not exceed one half that amount. The colonists would find it to their interest to turn their attention to such articles as this, for which there is an extensive demand at home, instead of confining themselves exclusively to the commoner and bulkier products, which they export at a much less profit, and which when once the market is fully supplied, may fall to a price at which they cannot afford to sell. The following is a calculation of the expenses generally supposed to attend a crop according to the mode of cultivation practised in Vaucluse:—

				£	s.	d.
Rent per hectare (2½ English acres), 3 years, at 165 francs,.....				19	17	6
Manure, 440 francs,.....	£17	12	6			
Carriage of ditto, 132 francs,.....	3	5	10			
				22	18	4
				£42	15	10

These expenses may almost be dispensed with in our colonies, as the soil at Vaucluse has long been exhausted.

(5050) MACLURA. A genus of plants belonging to the natural order Moraceæ. The fruit of Maclura aromatica, the Osage orange, is as large as the fist, orange coloured, and filled with a yellow fœtid slime, with which the native tribes smear their faces when going to war. The wood of *M. tinctoria* is the dye-wood called Fustic; it contains morine, a peculiar colouring substance; its fruit is pleasant, and used in North American medicine for the same purposes as the black mulberry in Europe. According to Martius, both the other species of the genus yield fustic in Brazil. (Lindley, *Vegetable Kingdom*).—*Eng. Cyc.*

(5051) MACLURA TINCTORIA. Urticaceæ.—This tree grows to the height of thirty or forty feet, from the wood Fustic, a yellow dye is obtained.—*Jaffrey.*

(5052) MACROCLADUS, Karen cabbage palm. A wild palm is found in many parts of the Tenasserim Provinces, which the Karens often cut down for the unexpanded bunches of young leaves found in its summit, and which has the taste of cabbage. The tree does not however, belong to the same genus as the cabbage tree of America, but from the imperfect specimens of its fructification that I have seen, appears nearly related to Griffith's genus.—*Mason.*

(5053) MACROPODIDÆ, a tribe of Brachyurous Decapodous *Crustacea* being the first of the family of *Oxyrhynchi* (Milne-Edwards), and nearly corresponding with the genus *Macropus* of Latreille, remarkable for the enormous length of their feet, which has obtained for them the name of Sea-Spiders and Spider-Crabs. This tribe is sometimes called *Leptopodiadæ*, after the genus *Leptopodia.*

Composcia (Leach; Latreille).—Carapace convex and nearly pyriform, but truncated anteriorly; rostrum rudimentary and scarcely reaching beyond the internal canthus of the orbits. Eyes supported upon peduncles, which are rather long, recurved anteriorly, and very large at their base; they are capable of being reflected backwards, but they are not retractile, for there is no post-foraminary orbital cavity for lodging them, their extremity being only protected by a spine of the lateral part of the carapace. The internal antennæ are reflected a little obliquely forwards; the fossets which lodge them have this particularity, namely, that they are not separated, as they are ordinarily, by a longitudinal portion, and form only a quadrilateral cavity. The first joint of the external antennæ is long and delicate, and is continued nearly as far as the rostrum, carrying at its extremity a moveable stem, which is consequently completely exposed. The epistome is nearly square, and the external jaw-feet are very much elongated, and only close the mouth imperfectly. The feet are slender and very long; in the female the first pair are the shortest, and are not stouter than the succeeding ones; those of the third, the fourth, and the fifth pair are a little longer, and are also terminated by a cylindrical nail slightly curved downwards. Form of the feet of the male, and disposition of the abdomen in this genus, not known. (Milne-Edwards.) The species are found in the seas of Asia. *C. retusa* may be taken as an example.

Egeria.—This genus is Asiatic in its geographical distribution, and M. Milne-Edwards divides it into two sections: the first with the third joint of the external jaw-feet deeply notched at its anterior and external angle (*E. arachnoides* and *E. Herbstii*), and the second with third joint of the external jaw-feet not notched at its anterior and external angle (*E. Indica*). *Doclea*—(Leach).—Carapace nearly globular, hairy, and more or less beset with spines; front raised. M. Milne-Edwards, who gives the specific character here stated, observes that the *Doclææ* bear the greatest anology to the *Egereæ*, and establish the passage between those *Macropodidæ* and *Libiniæ* which belong to the tribe of *Maiiadæ*. The species are found in the Indian Seas. *D. Rissonii*, whose locality is unknown, is given as an example.—*Eng. Cyc.*.

(5054) MACROURA, or MACRURA, the scientific name for that section of Crustaceans which have the abdomen, usually called the tail, long, in contradistinction from that section (*Brachyura*) which have the tail short. The Common Lobster is an example of a Macrurous Crustacean, and the Common Crab of a Brachyurous Crustacean, [Crustacea.]—*Eng. Cyc.*

(5055) MADDER.

This substance, which is so extensively used in dyeing red, is the product of the long slender root of the *Rubia tinctorum*, a plant of which there are several varieties. For England, the principal supplies of this important article of commerce are obtained from Holland, Belgium, France, Turkey, Spain, and the Balearic Isles, the Italian States, India, and Ceylon. The plant is generally raised from seed, and requires three years to come to maturity. It is, however, often pulled in eighteen months without injury to the quality; the quantity only is smaller. A rich soil is necessary for its successful cultivation, and when the soil is impregnated with alkaline matter, the root acquires a red color; in other cases it is yellow. The latter is preferred in England, from the long habit of using Dutch madder, which is of this color, but in France the red sells at two francs per cwt. higher, being used for the Turkey-red dye. Madder does not deteriorate by

keeping, provided it be kept dry. It contains three volatile coloring matters, madder purple, orange, and red. The latter is in the form of crystals, having a fine orange red color, and called Alizaine. This is the substance which yields the Turkey-red dye. The cheap root is employed in the East Indies as a substitute for madder, and so is the root of *Morinda citrifolia*, under the name of Sooranjee. Turkey madder roots realise about 30s. per cwt. About 1,100 tons are annually shipped from Naples, worth about £30 per ton. Madder has become an article of great request, on account of the fine scarlet colour produced from its roots, and is so essential to dyers and calico printers that without it they cannot carry on their manufactures. It is cultivated extensively in Holland, from whence it is imported in large quanties into both England and France, though it is cultivated to some extent in both countries. It has also been raised as a soiling crop, but the coloring matter is of so penetrating and subtile a character, that the flesh, milk, and even the bones of animals fed upon it are said to be tinged to a considerable degree with it. The soils best adapted, and which should be selected for its cultivation, are dry, fertile, and deep sandy loams ; the roots are long and fibrous, and descend to a depth of from two to three feet. It may be propagated by seed which, by some, is thought the best method, but the more usual mode is by the division of, and transplanting, the roots. The ground should be thoroughly and deeply pulverised, clean, and well-manured for the preceding crop, that the manure may be thoroughly rotted and incorporated with the soil : in April or May the suckers will be fit for taking from the older plantations — those of two or three years producing the best. The sets should have roots four or five inches long. Mark out rows two feet apart, with a line, and set the plant with a dibble, one foot apart in the rows. The roots should be dipped in a puddle of fine rich earth and water, beaten to the consistence of cream, previous to planting ; let the crown of the plant be clearly over ground, and secure the earth well around the root, to keep out drought. The plantation requires nothing more but to be kept perfectly clean and well-hoed during the summer months ; and after the top decays in the autumn, to be earthed up by the plough for the winter, each year, till the plants are three years old, when they are of the proper size and age for lifting, which must be done by trenching the land two feet deep—several hands accompanying the digger to pick out the roots, which must be thoroughly cleaned and dried on a kiln till they are so brittle as to break across, when they are fit to be packed in bags, and sold to the dye-stuff manufactures who grind and reduce them to powder for use. The produce is variable ; usually from eight to twenty cwt. per acre, but as much as 3,000 to 6,000 lbs. is frequently obtained. The forage amounts to about 15,000 lbs. the first year, and 7,500 lbs. the second year. In a new and good soil manure may be dispensed with for the first crop. Some cultivators interline and grow other crops between the rows, but the best cultivators state that such a practice is objectionable. The breadth of land under this crop in England is much reduced, in consequence of the reduction in price from the competition of the Dutch growers. Madder is extensively grown on the central table land of Affghanistan, forming one of the leading products of Beloochistan ; and, according to Mr. Pottinger, it sells in the Kelat bazar at about 10 lbs. for 2s. The cultivation there pursued is as follows : —The ground is repeatedly ploughed, and laid out finally in small trenches, in which the seed is sown, covered slightly with earth, and then the whole is flooded. Whilst thus irrigated, the trenches are filled with a mixture of rich manure and earth. The plants appear in about ten days, and attain a height of three or four feet during the first summer. They are cut down in September and used as a fodder for cattle. Subsequently, and until spring arrives, the ground is manured and repeatedly flooded. During the second year's growth, the plants which are intended to produce seed are set apart, but the stems of the remainder are cut every four or six weeks, in order to increase the size and goodness of the roots. Madder is said to repay a nett profit of 200 dollars to the acre, when properly managed. It produced on the farm of a gentleman, who has devoted some attention to this product in Ohio, at the rate of 2,000 lbs. per acre, and it may be made to produce 3,000 lbs., which is a greater yield than the average crops of Germany and Holland. Nine acres were planted by another person in the United States, in 1839, which he harvested in 1842. The labor required is said to be from 80 to 100 days work per acre. In the third year the stems are pruned as in the two preceding, and in September the roots are dug up. The roots are fusiform and thin, without any ramifications, and usually from three to five feet long. As soon as raised, they are immediately cut into small pieces and dried, and are then merchantable. Mr. Joseph Swift, an enterprising American farmer, of Erie county, Ohio, who occupies about 400 acres of choice land, mostly alluvial, in the valley of the Vermilion river, seven miles from Lake Erie, has detailed his practice in the "New Genesee Farmer" (an agricultural periodical), for March, 1843. His directions must be understood as intended for those who wish to cultivate only a few acres, and cannot afford much outlay of capital. Those who desire to engage in the business on an extensive scale, would need to adopt a somewhat different practice : —

Soil and preparation.—"The soil should be a deep, rich, sandy loam, free from weeds, roots, stones, &c., containing a good portion of vegetable earth. Alluvial "bottom" land is the most suitable, but it must not be wet. If old upland is used, it should receive a heavy coating of vegetable earth, from decayed wood and leaves. The land should be ploughed very deep in the fall, and early in the spring apply about one hundred loads of well rotted manure per acre, spread evenly, and ploughed in deeply; then harrow till quite fine and free from lumps. Next plough the land into beds four feet wide, leaving alleys between three feet wide, then harrow the beds with a fine light harrow, or rake them by hand, so as to leave them smooth and even with the alleys; they are then ready for planting.

Preparing sets and planting.—Madder sets or seed roots are best selected when the crop is dug in the fall. The horizontal uppermost roots (with eyes) are the kind to be used; these should be separated from the bottom roots, and buried in sand in a cellar or pit. If not done in the fall, the sets may be dug early in the spring, before they begin to sprout. They should be cut or broken into pieces, containing from two to five eyes each; *i. e.*, three or four inches long. The time for planting is as early in the spring as the ground can be got in good order, and severe frosts are over, which in the climate of America is usually about the middle of April. With the beds prepared as directed, stretch a line lengthwise the bed, and with the corner of a hole make a drill two inches deep along each edge and down the middle, so as to give three rows to each bed, about two feet apart. Into these drills drop the sets, ten inches apart, covering them two inches deep. Eight or ten bushels of sets are requisite for an acre.

After culture.—As soon as the madder plants can be seen, the ground should be carefully hoed, so as to destroy the weeds and not injure the plants; and the hoeing and weeding must be repeated as often as weeds make their appearance. If any of the sets have failed to grow, the vacancies should be filled by taking up parts of the strongest roots and transplanting them; this is best done in June. As soon as the madder plants are ten or twelve inches high, the tops are to be bent down on the surface of the ground, and all except the tip end covered with earth, shovelled from the middle of the alleys. Bend the shoots outward and inward in every direction, so as in time to fill all the vacant space on the beds, and about one foot on each side. After the first time covering, repeat the weeding when necessary, and run a single horse plough through the alleys several times to keep the earth clean and mellow. As soon as the plants again become ten or twelve inches high, bend down and cover them as before, repeating the operation as often as necessary, which is commonly three times the first season. The last time may be as late as September, or later if no frosts occur. By covering the tops in this manner, they change to roots, and the design is to fill the ground as full of roots as possible. When the vacant spaces are all full, there is but little chance for weeds to grow; but all that appear must be pulled out.

The second year.—Keep the beds free from weeds: plough the alleys and cover the tops as before directed, two or three times during the season. The alleys will now form deep and narrow ditches, and if it becomes difficult to obtain good earth for covering the tops, that operation may be omitted after the second time this season. Care should be taken, when covering the tops, to keep the edges of the beds as high as the middle; otherwise the water from heavy showers will run off, and the crop suffer from drought.

The third year.—Very little labor or attention is required. They will now cover the whole ground. If any weeds are seen, they must be pulled out; otherwise their roots will cause trouble when harvesting the madder. The crop is sometimes dug the third year; and if the soil and cultivation have been good, and the seasons warm and favorable, the madder will be of a good quality; but generally it is much better in quality, and more in quantity, when left until the fourth year.

Digging and harvesting.—This should be done between the 20th of August and the 20th of September. Take a sharp shovel or shovels, and cut off and remove the tops with half an inch of the surface of the earth; then take a plough of the largest size, with a sharp coulter and a double team, and plough a furrow outward, beam deep, around the edge of the bed; stir the earth with forks, and carefully pick out all the roots, removing the earth from the bottom of the furrow; then plough another furrow beam-deep as before, and pick over and remove the earth in the same manner; thus proceeding until the whole is completed.

Washing and drying.—As soon as possible after digging, take the roots to some running stream to be washed. If there is no running stream convenient, it can be done at a pump. Take large round sieves, two-and-a-half or three feet in diameter, with the wire about as fine as wheat sieves; or if these cannot be had, get from a hardware store sufficient screen wire of the right fineness, and make frames or boxes, two and-a-half feet long and the width of the wire, on the bottom of which nail the wire. In these sieves or boxes, put half a bushel of root at a time, and stir them about in the water, pulling the branches apart so as to wash them clean; then, having a platform at hand, lay them on to dry. (To make the platform, take two or three common boards, so as to be about four feet in width, and nail deals across the under side). On

these spread the roots about two inches thick for drying in the sun. Carry the platforms to a convenient place, not far from the house, and place them side by side, in rows east and west, and with their ends north and south, leaving room to walk between the rows. Elevate the south ends of the platforms about eighteen inches, and the north ends about six inches from the ground, putting poles or sticks to support them —this will greatly facilitate drying. After the second or third day's drying, the madder must be protected from the dews at night, and from rain, by placing the platforms one upon another to a convenient height, and covering the uppermost one with board. Spread them out again in the morning, or as soon as danger is over. Five or six days of ordinarily fine weather will dry the madder sufficiently, when it may be put away till it is convenient to kiln-dry and grind it.

Kiln-drying.—The size and mode of constructing the kiln may be varied to suit circumstances. The following is a very cheap plan, and sufficient to dry one ton of roots at a time. Place four strong posts in the ground, twelve feet apart one way, and eighteen the other: the front two fourteen feet high, and the other eighteen: put girts across the bottom, middle, and top, and nail boards perpendicularly on the outside as for a common barn. The boards must be well seasoned, and all cracks or holes should be plastered or otherwise stopped up. Make a shed-roof of common boards. In the inside put upright standards about five feet apart with cross-pieces to support the scaffolding. The first cross-pieces to be four feet from the floor; the next two feet higher, and so on to the top. On these cross-pieces lay small poles, about six feet long and two inches thick, four or five inches apart. On these scaffolds the madder is to be spread nine inches thick. A floor is laid at the bottom to keep all dry and clean. When the kiln is filled, take six or eight small kettles or handfurnaces, and place them four or five feet apart on the floor (first securing it from fire with bricks or stones), and make fires in them with charcoal, being careful not to make any of the fires so large as to scorch the madder over them. A person must be in constant attendance to watch and replenish the fires. The heat will ascend through the whole, and in ten or twelve hours it will all be sufficiently dried, which is known by its becoming brittle like pipe stems.

Breaking and grinding.—Immediately after being dried, the madder must be taken to the barn and threshed with flails, or broken by machinery (a mill might easily be constructed for this purpose), so that it will feed in a common grist-mill. If it is not broken and ground immediately, it will gather dampness so as to prevent its grinding freely. Any common grist-mill can grind madder properly. When ground finely it is fit for use, and may be packed in barrels like flour for market.

Amount and value of product, &c.—Mr. Swift measured off a part of his ground, and carefully weighed the product when dried, which he found to be over two thousand pounds per acre, notwithstanding the seasons were mostly dry and unfavourable. With his present knowledge of the business, he is confident that he can obtain at least three thousand pounds per acre, which is said to be more than is often obtained in Germany. The whole amount of labor he estimates at from eighty to one hundred days' work per acre. The value of the crop, at the usual wholesale price (about fifteen cents per pound), from three to four hundred dollars. In foreign countries it is customary to make several qualities of the madder, which is done by sorting the roots; but as only one quality is required for the western market, Mr. Swift makes but one, and that is found superior to most of the imported, and finds a ready sale. Madder is produced in Middle Egypt to some extent, for the consumption of the country, principally for dyeing the *tarbouche* or skull caps which are universally worn. Its culture was introduced in 1825. In 1833 300 acres in Upper Egypt, and 500 in the Delta and the Kelyout, were devoted to madder roots. New S. Wales is eminently suited to the culture of this valuable root, and as the profits upon its cultivation are very large, it is strongly recommended to the attention of agriculturists there. The article produces to France an annual sum of one million sterling; the price of the finest quality in the English market being £60 per ton. Its yield varies from £40 to to £50 per acre, and the expenses upon its proper culture should not exceed one half that amount. The colonists would find it to their interest to turn their attention to such articles as this, for which there is an extensive demand at home, instead of confining themselves exclusively to the commoner and bulkier products, which they export at a much less profit, and which when once the market is fully supplied, may fall to a price at which they cannot afford to sell. The following is a calculation of the expenses generally supposed to attend a crop according to the mode of cultivation practised in Vaucluse:—

				£	s.	d.
Rent per hectare (2½ English acres), 3 years, at 165 francs,				19	17	6
Manure, 440 francs,	£17	12	6			
Carriage of ditto, 132 francs,	3	5	10			
				22	18	4
				£42	15	10

These expenses may almost be dispensed with in our colonies, as the soil at Vaucluse has long been exhausted.

Two and a-half acres require 170 lbs. seed, at 2½d. per pound, which, with the labor afterwards bestowed, including the cost of spade trenching, will be,.....	30	0	0
	£72	15	10

The average produce per hectare is 77 cwt., which, at £1 4s. 2d. per cwt. (the price on the spot), is £93. The price is now much lower, but still it is clear a most profitable return would be derived from the first crop, and a proportionately larger one afterwards. A considerable portion of the madder roots, instead of being ground and exported in that form, as heretofore, is now exposed, after being invested with dilute sulphuric acid, to a boiling heat by means of steam, by which the coloring matter is considerably altered and improved in quality for some dyeing processes, while the quantity rendered soluble in water is greatly increased. The madder so prepared is known as "garancine," and forms an important branch of manufacture in the south of France, which was well illustrated at the Great Exhibition in 1851, by a collection of specimens supplied by the Chamber of Commerce of Avignon. The spent madder, after being used in dyeing, is now also converted by Mr. H. Steiner, of Accrington, into a garancine (termed *garancense* by the French) by steaming it with sulphuric acid in the same manner as the fresh madder, and thus a considerable quantity of coloring matter is recovered and made available which was formerly thrown away in the spent madder. Both varieties of garancine give a more scarlety red than the unprepared madder, and also good chocolate and black, without soiling the white ground, but are not so well fitted, particularly the garancine of spent madder, for dyeing purples, lilacs, and pinks. The value of the garancine imported from France in 1848 was £59,554, and of that imported in 1851, £93,818. This preparation of ground madder is imported into Liverpool to the extent of from 500 to 600 tons annually from Marseilles, for the use of calico printers in the manufacturing districts. The price is £7 to £8 the ton. This important root is already cultivated to considerable extent in Russia, but not nearly in sufficient quantity to meet the local demand; so that large quantities are imported from Holland and elsewhere, every year. The quantity of madder, madder-root, and garancine annually imported into the United Kingdom is exceedingly large, over 15,000 tons, as is shown by a reference to the following figures:—

	Madder. cwts.	Madder roots. cwts.	Garancine. cwts.	Total. cwts
1848	81,261	39,463	5,955	276,679
1849	92,736	161,986	4,969	259,691
1850	100,248	161,613	5,845	267,706
1851	92,925	202,091	9,382	304,398
1852	84,385	179,813	—	—

We imported from France, duty free, the following:—

	Madder. cwts.	Official value. £	Madder root. cwts.	£
1848	54,084	122,851	25,068	70,749
1849	57,108	131,050	23,459	81,274
1850	54,559	123,628	13,693	55,265
1851	65,577	151,502	34,017	107,721

The price in the Liverpool market, in June 1853, for Bombay madder-roots was £1 18s. to £2 14s the cwt. Indian madder, from the *Rubia cordifolia*, or *Munjestha*. This is a variety with white flowers, a native of Siberia, is cultivated largely in the East, particularly about Assam, Nepaul, Bombay, Scinde, Quetta, China, &c., for its dyestuff, and is known as Munjeet. A small quantity is exported from China and India; about 338 Indian maunds were shipped from Calcutta in 1840, and 2,328 in 1841. It fetches in the London and Liverpool markets from 20s. to 25s. and 30s. per cwt., duty free; 405 tons were imported into Liverpool from Bombay and Calcutta in 1846, and 525 tons in 1850, but none was imported in 1851 and 1852. It was remarked by the Jury in 1851, at the Great Exhibition, that this is a valuable dye-stuff, and hitherto not so well appreciated as it deserves, for some of the colours dyed with it are quite as permanent as those dyed with madder, and even more brilliant. Its use however is gradually increasing, and it is unquestionably well worthy the attention of dyers.—*Simmonds.*

(5056) MADEIRA WINE. So called from the island bearing that name, where it is made. The wines of Madeira have latterly fallen into disrepute in England, owing partly to the frequency of adulteration, and partly to the preference given to Sherry and French Wines.—*Faulkner.*

(5057) MADIA ELEGANS. Compositæ. This is a plant of no particular beauty, the flowers of which are yellow, and may be grown easily from seed, in any common soil.—*Riddell.*

(5058) MADOORKATI. Papyrus Pangorei, is a Sedge, extremely common about Calcutta, and is very extensively employed in Bengal for making the elegant, shining useful mats for which the Capital of India is famous, and which are frequently imported into Europe. Strips of this sedge are suited for platting.—*Royle.*

(5059) MAGNESIA.

Gebraunte magnesia, Ger.	Magnesia, It. Magnesie, Fr.

A well-known medicinal and primitive earth, having a metallic base. It is not found native in a state of purity, but is commonly prepared by burning the carbonate of magnesia, whence it is sometimes termed *Calcined magnesia*. It is a white, soft powder, possessing neither taste nor smell. The carbonate of magnesia is found in a natural state in Piedmont, Moravia, Hoboken in

North America, and Southern India, but it is chiefly manufactured from the bittern of sea-salt works.—*Faulkner*. This *bittern* of sea-water, after the crystallization of Common Salt, contains Sulph. Magnesia and Chlor. Magnesium. By simple evaporation the Sulph. Magnesia may be separated by crystallization. Sometimes Sulphuric Acid is added to convert the Chloride into a further quantity of Sulp. Magnesia. At Lymington, in Hampshire, two kinds of Epsom Salt are manufactured. The first, called *single*, obtained by the cooling down of a concentrated solution in wooden troughs, is moist, and contains a considerable quantity of Chloride. When redissolved and recrystallized, the second, which is called *double* Epsom Salt, is obtained; this is pure, and permanent in ordinary states of the atmosphere. Sulph. Magnesia is also prepared from Dolomitic Limestone, that is, Carbonates of Lime and Magnesia mixed together in various proportions. One method is to heat this Magnesian Limestone and to decompose it with diluted Sulphuric Acid. Sulphate of Lime, which is insoluble, is formed, as well as Sulph. Magnesia which, being soluble in water, is easily separated and purified by crystallization; or the mineral may be calcined, when the Carbonic Acid, being expelled, the caustic Lime and Magnesia are first hydrated by being moistened with water, and then the Lime converted into Chloride of Calcium, by adding only sufficient H. Cl. to effect this object. The Chloride being readily soluble in water, is by its means easily separated from the Magnesia, which is converted into the Sulphate by the addition of Sulphuric Acid, or of Sulphate of Iron; or the Hydrated Lime and Magnesia may be boiled with bittern. Chlor. Calcium is formed and remains in solution while the magnesia and the bittern is separated and obtained tolerably pure with the Magnesia of the dolomitic limestone and may be converted as before into sulphate of Magnesia.—*Royle*.

(5060) MAGNESIA ALBA. MAGNESIÆ SUBCARBONAS. Kohlensaure Talkerde.

Carbonate de Magnesie, Fr. | Kohlensaure Bittererde. Ger.

Carbonate of Magnesia (Mg_0,C_{02} =42), at first called *Magnesia alba*, and *Comitissæ Palma pulvis*, was used as a medicine by the Count de Palma at Rome, whence it was also called *Pulvis albus Romanus*. It was introduced into the list of the Materia Medica by F. Hoffman. It is found in nature in some mineral waters, in some of which, however, it may exist in the form of the Bicarbonate. In an impure state it forms a constituent of Dolomitic, that is, of Magnesian Limestone, and in a comparatively pure state, a hill in the Peninsula of India, consisting of Magnesia 46, Carbonic Acid 51, Insoluble Matter 1.5, Water 0·5, loss 1=100. Pure Carbonate of Magnesia is sometimes found in nature in rhombohedral crystals.—*Royle*, *page* 121.

(5161) MAGNESIA LOZENGES. Carbonate of magnesia six ounces, sugar three ounces, nutmeg one scruple. Pulverize and with tragacanth mucilage make into lozenges.—*Beng. Phar. p.* 435.

(5062) MAGNESIA, SULPHATE OF. To prepare the sulphate of Magnesia from the Magnesite of Southern India, take Magnesite powdered two pounds, sulphuric acid one pound, and water one gallon. Mix the acid and water and boil in a porcelain vessel. When boiling, add the powdered magnesite gradually and boil, stirring with a glass-rod till a slip of reddened litmus paper recovers its blue colour in the solution; filter while hot, and concentrate in a porcelain capsule till a pellicle begins to form on the surface of the liquor. Set aside for twenty-four hours to crystalize. Any corresponding quantities of the ingredients may be used, and in large operations leaden pans may be employed. The magnesite of Madras is a white, hard mineral, composed of one equivalent of carbonic acid and one equivalent magnesia. It contains no water is very brittle, and is readily reduced to a fine powder by stamping in a metal or stone mortar; one of stone should be preferred with a heavy stone or hardened iron pestle. In the above process, the sulphuric acid displaces the carbonic acid. The solution is slow, unless promoted by heat, and with the quantity of water specified, gives more rapid decomposition than with a greater or less proportion. Where carbonate of magnesia is to be manufactured, the thick mother liquor from which this salt has crystalized, may be used for precipitation by the carbonate of soda, the quantity required being ascertained by an experiment on one fluid ounce. In England this salt is prepared from magnesian limestone by a much more tedious and troublesome process than that above recommended. Formerly it was manufactured from the bittern of salt works, but this method has been long abandoned, as the product was found, notwithstanding every precaution, to deliquesce on exposure to moist air. Bittern can be found in many localities in Southern Asia, while magnesite must be obtained from Madras. Bittern is the liquor which remains at the salt works after common salt has been separated by boiling. It is acrid and bitter; of yellowish colour, strongly impregnated with iron, contains muriates of lime and magnesia, and bromide (and often iodide and chloride of sodium, potassium, and other metallic bases. To prepare the sulphate of magnesia, take of bittern one gallon, solution of carbonate of soda as much as required. Mix the solutions intimately adding the carbonate of soda while any precipitate occurs, filter through cloth and wash Magnesia with water till the washings are tasteless, and do not precipitate with nitrate of

of baryta, compress the precipitate by screw pressure. The precipitate is a mixture of carbonate of magnesia and carbonate of lime in variable proportions. Dry one hundred grains of the pressed precipitate on a water bath, and ascertain thus the proportion of water. Take of the press-cake as much as would give in the dried state two pounds, sulphuric acid one pound, water one gallon, dissolve by a gentle heat, filter and concentrate till it becomes turbid, Allow it to cool and filter again, this separates much of the sulphate of lime, now boil down till a pellicle forms, and set aside to crystalize. The mother liquor should be rejected This process is troublesome and comparatively unproductive. The product is always contaminated by sulphates of lime and iron, and although by the modification introduced of precipitating by carbonate of soda, it is freed from muriate of lime, still the article is in every repect inferior to that prepared from magnesite. Magnesian limestone, abounds in Sylhet. The sp. gr. is 2·86 ; it is of yellowish-brown or greyish colour, soluble slowly in dilute muriatic acid with effervescence. It contains one eq. of carbonate of lime=50, and one eq. carbonate of magnesia=42. In order to prepare from it the sulphate of Magnesia, it should be stamped to coarse powder and boiled in dilute sulphuric acid in leaden pans, the sulphate of lime will gradually deposit, and the sulphate of magnesia will crystalize from the concentrated solution. The process is difficult, the product never so pure as that from the magnesite. Dr. Henry first subjects the powdered stone to the action of dilute muriatic acid, which acts on the lime before the magnesia. The liquor should be tested from time to time, and when a little precipitates copiously by ammonia, the muriatic acid should be decanted, the powder well washed with soft water, and then disolved by boiling dilute sulphuric acid on the plan mentioned under the first head. Where acids are very cheap, this process, although more tedious, is the most economical of all, and affords a very pure product.—*Beng. Phar. p.* 334.

(5063) MAGNESITE, CARBONATE OF MAGNESIA, occurs in acicular crystals, massive, and in powder. Its colour is usually white, occasionally grayish and yellowish. The massive varieties are found amorphous, reniform, nodular, and stalactitic. Fracture splintery, or flat conchoidal. Its hardness exceeds that of calc-spar. It is dull, nearly opaque. Specific gravity 2.8. It is found in several parts of Europe, as Styria, Moravia, Spain, and Silesia, in Peninsular India, and at Hoboken, in New Jersey, North America. Its analysis by Rammelsberg gives—

Carbonic Acid	52.214
Magnesia	47.786
	——100

Eng. Cyc.

(5564) MAGNET, NATIVE. [IRON][Loadstone.

(5065) MAGNOLIA, a genus of Plants named in honour of Pierre Magnol, who was professor of medicine and prefect of the botanic garden of Montpellier. He was born in 1638, and died in 1715. He gave an account of the plants growing wild about Montpellier, in a work entitled 'Botanicum Monspeliense; seu Plantarum circa Monspelium nascentium Index,' 8vo., 1686. This work, illustrated with plates, as well as one published in 1689 with the title 'Prodromus Historiæ Generalis Plantarum in quo Plantæ per Families disponuntur,' was arranged according to a natural system of his own. In another work embracing the plants growing in the Montpellier Garden, entitled 'Hortus Regius Monspeliensis,' he has arranged the plants according to the system of Tournefort. The genus *Magnolia* is the type of the natural order *Magnoliaceæ*. It has a calyx of 3 deciduous sepals that resemble petals; the corolla is composed of 6 to 9 petals; the stamens and pistils numerous; the carpels are disposed compactly in spikes, opening by the external angle, 1-2-seeded, permanent; the seeds baccate, somewhat cordate, pendulous, hanging out beyond the carpels by a very long umbilical white thread. The species of *Magnolia* are trees or shrubs, with alternate, stipulate, deciduous, or evergreen simple leaves, and large terminal solitary odoriferous flowers. They are all natives of North America and Asia.—*Eng. Cyc.*

(5066) MAGNOLIA ACUMINATA, a deciduous tree with oval acuminate leaves, the under surface pubescent, the flowers with from 6 to 9 petals: It is a native of North America, from Pennsylvania to the Carolinas. The flowers are large, 3 or 4 inches in diameter, of a yellowish colour, mixed with faint blue or pea-green, but not remarkable for their beauty. The fruit is about 3 inches long, and resembles a small cucumber, whence in America it is called Cucumber-Tree. A tincture is made of the fruit, and is used in cases of rheumatism. Several varieties of this plant have been described. It is often used in the London nurseries as a stock on which to engraft the other species. There are several other species of this magnificent genus found in the forests of North America, all of which are valued in Great Britain for ornamental culture. The best known of these are *M. cordata*, the Heart-Leaved Cucumber-Tree, with yellow flowers streaked with red, and having a disagreeable odour; and *M. auriculata*, Indian Physic, or Long-Leaved Cucumber-Tree, having white flowers and a bitter bark, which is used as a medicine by the Indians.—*Eng. Cyc.*

(5067) MAGNOLIA EXCELSA. Near Darjeling, the white-flowered magnolia (*M. excelsa*, Wall,) forms a predominant tree at 7000 to 8000 feet; and in 1848 it blossomed so profuse-

ly, that the forests on the broad flanks of Sinchul and other mountains of that elevation, appeared as if sprinkled with snow. The purple-flowered kind again (*M. Campbellii*) hardly occurs below 8000 feet, and forms an immense, but very ugly black-barked, sparingly branched tree, leafless in winter and also during the flowering season, when it puts forth from the ends of its branches great rose-purple cup-shaped flowers, whose fleshy petals strew the ground. On its branches, and on those of oaks and laurels, *Rhododendron Dalhousiæ* grows epiphytically, a slender shrub, bearing from three to six white lemon-scented bells, four and a half inches long and as many broad, at the end of each branch. In the same woods the scarlet Rhododendron (*R arboreum*) is very scarce and is outvied by the great *R. argenteum*, which grows as a tree forty feet high, with magnificent leaves twelve to fifteen inches long, deep green, wrinkled above and silvery below, while the flowers are as large as those of *R. Dalhousiæ*, and grow more in a cluster. Dr. Hooker knows nothing of the kind that exceeds in beauty the flowering branch of *R. argenteum*, with its wide spreading foliage and glorious mass of flowers.—*Hooker Him. Jour. Vol.* I. *p.* 125.

(5069) MAGNOLIA GLAUCA, deciduous Swamp Magnolia, is an almost deciduous plant, with obtuse elliptical leaves, glaucous on the under surface: the flowers from 9-14-petalled, contracted; the petals ovate, concave. This species is a tree rising from 15 to 20 feet in height. It is a native of North America, in low, moist swampy ground at a little distance from the sea, from Massachusetts to Florida and Louisiana. This plant is also cultivated, and a number of varieties have been described. The bark has a bitter and aromatic odour resembling sassafras. On this account it has been used in America as a substitute for other aromatic bitter barks as Cascarilla, Canella &c., and, it is said, with great success. Although not much used in Europe, very favourable reports of its efficacy in chronic rheumatism, ague, and remittent fever have been given. All the species of *Magnolia* possess more or less the properties which are most evident in *M. glauca*. When used, a tincture made from the bark, seeds, or cones is equally efficacious. It is said that when the tincture is made from the leaves and cones whilst green, it is more efficacious. In America this tree is known by the names White Laurel, Swamp Laurel, Swamp Sassafras, Sweet Bay, and Beaver-Tree. The last name is given to it on account of the fondness of the beaver for it. The flowers are of a cream colour and have a sweet scent, which Kalm says may be perceived at a distance of three miles. The flowers are followed by red berries, which give the tree a handsome appearance. The berries are steeped in brandy and used as a domestic medicine for various complaints.—*Eng. Cyc.*

(5070) MAGNOLIA GRANDIFLORA, many varieties; they are scarcely hardy enough to live in Britain away from the shelter of a wall, except quite in the south; unprotected specimens exist however near Edinburgh. *Magnolia grandiflora* has been introduced into China from America and promises to be a very ornamental tree.—*Fortune's Tea Districts, p.* 16.—*M. grandiflora*, The Great-Flowered Magnolia, or Laurel Bay, is an evergreen tree, reaching sometimes a height of 70 feet. It has oval-oblong coriaceous leaves with the upper surface shining and the under surface rusty; the flowers erect, with from 9 to 12 petals expanding. This plant is one of the tallest and handsomest trees of North America. It has large pale-green shining leaves, nearly 10 inches long, with large white flowers. It has been cultivated in England for the last century, and in that country attains a height of from 30 to 40 feet. Several varieties of this species have been named and described. Amongst the most constant and best known varieties are—1, *M. g. obovata*; 2, *M. g. Exoniensis*; 3. *M.g. angustifolia*; 4, *M. g. præcox*. The first is known in the Carolinas by the name of the Big Laurel; the second is the Exmouth Magnolia; the third and fourth are varieties which have been produced in France. In the cultivation of this species a deep sandy loam, dry at bottom, and supplied with vegetable mould, suits all the varieties. In planting it against a wall, almost any aspect may be chosen except a north-east. This plant may be propagated by stools, which should be laid down in autumn, and require two years before they are fitted for separation. They are then potted, and kept in pits or under glass during the winter. It may be also propagated by seeds from America.—*Eng. Cyc.*

(5071) MAGNOLIA PURPUREA, the Purple-Flowered Magnolia, is a deciduous shrub, with obovate-acute reticulately-veined leaves, almost smooth; the flowers erect, of 3 sepals and 6 obovate petals: the styles very short. This plant is a native of Japan, and seldom attains a greater height than 10 feet. The bark when bruised has an aromatic odour. The flowers are more or less purple without, and always white within. It is a very ornamental species and worthy of cultivation. The best situation for it in England is against a wall, when its branches will reach from 15 to 20 feet.—*Eng. Cyc.*

(5072) MAGNOLIA UMBRELLA is a deciduous tree with lanceolate spreading leaves, the adult ones smooth, the younger ones pubescent underneath; the petals 9-12, exterior ones pendent. It is a native of North America, in the Carolinas, Georgia, Virginia, and New York. The leaves are one to two feet long, placed at the ends of the branches in a circular manner, somewhat in the form of an umbrella, from which circumstance it has been called the Umbrella-Tree. The wood is soft and spongy, and on the

mountains of Virginia is called Elmwood.—*Eng. Cyc.*

(5073) MAGNOLIA YULAN, OR MAGNOLIA CONSPICUA, a deciduous tree with obovate abruptly acuminated leaves, the younger ones pubescent, expanding after the flowers; the flowers erect, 6-9-petalled; the styles erect. This plant attains a height of 30 or 40 feet in its native country, but reaches only 8 or 10 feet in English gardens. It grows in China, where it has been cultivated since the year 627. Its native name is Yulan. It is a very showy tree, having white flowers sometimes suffused with purple, which give out a most delicious perfume. It blossoms in England from February to April, and is distinguished from the other species by the flowers appearing before the leaves. It is not quite so hardy as the American species; still, unless the weather is unpropitious, it will put forth an abundance of blossoms during the dreary months of February and March.—*Eng. Cyc.*

(5074) MAGNOLIACEÆ: MAGNOLIADS, an important natural order of albuminous polypetalous Exogenous Plants, consisting of bushes and trees, inhabiting the temperate parts of both the Old and New World. They have the numerous disjoined carples and hypogynous stamens of *Ranunculaceæ*, to which they are closely allied; they differ not only in their arborescent habit, but in the young leaves being enveloped in stipules, either horn-like and convolute, or bivalved, which are thrown off as the leaves unfold. The flowers are usually large and sweet-scented, and the leaves are firm, broad, and large, in consequence of which many of the species are objects of cultivation in all civilised countries. In England, where they are exotics, they are among the most highly-valued of ornamental plants, and every species which can bear the climate, or which will thrive in conservatories, has been collected with great care, whenever opportunities have offered, so that few now remain to be imported. Among the most ornamental of the hardy kinds are the *Magnolia grandiflora* of Caroiina; *M. glauca*, of which there are many varieties; *M macrophylla*, the flowers of whch are among the largest in the vegetable kingdom; and the Tulip-Tree, *Liriodendron tulipifera*, a large tree with singular truncate leaves. In Bengal the air is often perfumed with the fragrance of the Champac, a species of *Michelia*; while in China and the Malayan Archipelago others are equally well known for their ornamental characters. Nor are the plants of this order less useful than beautiful. It is probable that they are all valuable for the febrifugal qualities of their bark. *Magnolia glauca* is among the best bitter and aromatic species known in medicine, and the Tulip-Tree affords to the North American settler a substitute scarcely inferior to it. The genera *Talauma* and *Magnolia* have the very singular property of dropping their seeds out of the back of the seed-vessels when ripe, allowing them to hang down, each suspended by a long extensible elastic cord, composed of delicate spiral vessels. In consequence of the seeds of *Magnoliaceæ* containing an abundance of oil which often becomes rancid soon after they are gathered, it is difficult to transport them to a considerable distance in a living state. The best method of succeeding in that object is to pack the seeds in earth as soon as they are ripe, pressing them close and securing them in a box. Under such circumstances they will preserve their vitality for several months. There are 11 genera and 65 species of this family.—*Eng. Cyc.*

(5075) MAHASER, A very large Carp, found by Dr. Hooker in the Teesta River, near Rangamally in the Terai.—*Hooker. Him. Jour. page* 398 *Vol.* 1.

(5076) MAHOGANY.

Caoba, Sp.

Swietenia mahogani, indigenous in the West Indies and Central America, and naturalized in some parts of India. There are two East Indian species of this genus the, *S. febrifuga*, a gigantic tree, growing in the mountainous parts of Central Hidoostan; its wood is of a dull red colour, hard, heavy, and durable; and the *S. choloroxylon*, a smaller tree found in the mountains of the Circars; its wood is of a yellow colour resembling box.—*Faulkner.* Mahogany however (Swietenia Mahogani) is the most important species of this small genus of plants, named in honour of Gerard van Swieten, a physician of Leyden. It is a native of Campeachy and of the West Indies, where it is a lofty tree with a large spreading head and glossy pinnate leaves. The trunk frequently exceeds 40 feet in length, with a diameter of 6 feet. The timber, well known for its general use in furniture and cabinet making, is of a rich red-brown, of different shades and markings, capable of a brilliant polish, close-grained, very little liable to warp or shrink, and having a semi-resinous juice which preserves the wood from the attacks of insects. Mahogany is imported from several of the West India islands, and from the Spanish main. It arrives in logs about 10 feet long and 2 feet square. Honduras mahogany is imported in logs from 2 to 4, or even 6 feet square, and from 12 to 28 feet long. This variety is lighter in colour, and more open and irregular in grain than the Spanish. By some botanists the Honduras mahogany has been described as a different species; but it appears probable that differences of soil and situation have produced the variations in quality. These woods called mahogany, brought from Africa and the East, belong to other genera, and are decidedly inferior to the true mahogany. A specimen of the latter, however, was sent from the Botanic Garden, Calcutta, to the Great Exhibition

and its fine quality proved that the true variety may be raised in the East Indies. The value of the best Spanish mahogany may be judged of by the fact, that the Messrs. Broadwood gave £3,000. for three logs of fine mahogany, each 15 feet long and 38 inches square. These logs were the produce of a single tree. The wood was exceedingly beautiful, and when polished, it reflected the light in a varied manner, offering a different figure in whatever direction it was viewed. These logs were brought to England with a full knowledge of their value; but generally speaking, the purchase of this wood is a sort of lottery. Dealers in mahogany often introduce an auger before buying a log: but this does not always enable them to judge with precision respecting the quality of the timber. Honduras mahogany grows mostly upon moist low land, is generally soft, coarse, and spongy. It has, however the advantage of holding glue admirably, and is in consequence, much used as ground on which to place veneers of the finer sorts of mahogany. The cutting of mahogany at Honduras is carried on twice a year—at Midsummer and soon after Christmas. The mahogany of Cuba and Hayti, and of the islands in general, is close-grained, dark coloured, and sometimes highly figured: it is known as Spanish mahogany. The general appearance of the tree is extremely beautiful, and has been thus described:—"In the rich valleys among the mountains of Cuba, and those that open upon the bay of Honduras, the mahogany expands to so giant a trunk, divides into so many massy arms, and throws the shade of its shining green leaves, spotted with tufts of pearly flowers, over so vast an extent of surface, that it is difficult to imagine a vegetable production combining in such a degree the qualities of elegance and strength of beauty and sublimity." Mahogany may be safely pronounced the most useful of all furniture wood, for which it is particularly adapted on account of its size, abundance, durability, and beauty, and from the fact that it holds the glue better that any other wood. It is much used for founders' patterns, and other works in which permanence of form is of great consequence. It is also employed for a variety of turned works. Mahogany, in common with all other large foreign woods, requires to be carefully dried after it is cut into planks, as, notwithstanding the long time which may intervene between the felling and the using, it continues, so long as it is in the log, to retain much of its moisture. Well-seasoned Spanish mahogany cuts well, takes a brilliant polish, resists scratches, stains, and fractures much better than inferior sorts, and is worth the trouble and delicate workmanship which are often expended upon it. The colours are brought out by the application of oil or varnish, but much washing or soaking of the wood in water will destroy its beauty and render it of a dingy brown. The colour of mahogany is often artificially deepened by alkaline applications, but the best effect is produced by the use of a colourless varnish, which allows the natural tints of the wood to be displayed unaltered. From the resemblance of the seed-vessel of the mahogany-tree to that of the Barbadoes cedar, the name of cedar has been sometimes erroneously applied to it. There is so far a correspondence in the nature of these trees that the mahogany, like the pine tribe, succeeds best upon the coldest soils and in the most exposed situations. When it grows on moist soils and warm lands, it becomes coarse and spongy, and the timber is not secure from the attacks of worms. The first mention of this beautiful timber occurs in 1597, when it was used to repair some of Sir Walter Raleigh's ships at Trinidad. Yet the timber was not brought to England until about the beginning of the last century, when a few planks brought over as ballast in a vessel from the West Indies, were given to Dr. Gibbons, and would have been used, but for their hardness, by his workmen in erecting a house in Covent Garden. Having been rejected by them, a piece was given to a cabinet maker, named Wollaston, with the request that he would make a candle-box of it. This being done, the candle-box proved so beautiful that it became an object of curiosity, and the despised mahogany came into great request, and was soon established as a valuable material for household furniture.—*Tomlinson.* The genuine mahogany tree may be seen in some Tenasserim gardens, where it appears to flourish.—*Mason.* The Mahogany grows as well in Bengal as in its native country, and though inferior in fineness of grain to the best kinds, it is at least equal in quality to that of Jamaica. As an instance of the imperceptible manner in which useful plants are introduced into, and distributed through a country, we may adduce the Mahogany, as Dr. Roxburgh in a paper presented to the Society of Arts in 1806, on the growth of Trees in the Botanic Garden at Calcutta, mentions that two plants (and these were the first introduced into India) were sent by the Honourable the Court of Directors to the Botanic Garden in 1795, and by the end of 1804, above five hundred plants had been reared from these two. It succeeds so perfectly well in the East Indies, that the tree will, without doubt, in a few years, form a valuable acquisition to that country.—Soc. of Arts Trans. vol. xxiv. p. 154 —The tree is now common in Northern as well as Southern India, yet so little is known of such subjects, that some seed was sent to India only a few years ago by the overland mail.—*Royle's Productive Resources of India.*

(5077) MAIDEN HAIR, the common name of the *Adiantum Capillus Veneris*, a fern found wild in many parts of Europe, on damp shaded rocks. It is the Adianton (Ἄδιαντον) of the

Greeks, and has probably gained its trivial name from its having formed a part of the preparations used by the ladies for stiffening their hair. (Dioscorides, l. iv. c. 136.) [ADIANTUM.]—*Eng. Cyc.*

(5078) MAIN-PHUL, Vanguiera spinosa. The tree grows in Marwar: the dried fruit which is used, is considered stimulating; and when given to cattle in the cold weather prevents their suffering from the cold: not given to mankind; three seers for one rupee,—*Gen. Med. Top. p.* 146.

(5079) MAI RUBIYA, a dried fish brought from Delhi: considered good in impotency; four tolas for one rupee.—*Gen. Med. Top. p.* 147.

(5080) MAI-SUTR-ARABI, blood which has congealed in the belly of a young camel; after being overfed, the young camel is driven about violently, and then killed, and the blood extracted; is brought from Bombay and Delhi; supposed to benefit in impotency: one tola costs three rupees.—*Gen. Med. Top. p.* 147.

(5081) MAIZE. INDIAN CORN, ZEA-MAYS.

Mokka, BENG.	GranoTurcoo Siciliano, IT.
Bled de Turquie, FR.	Jagung Malay, JAV.
Turkisch korn, Mays, GER.	Trigo de Indias, Trigo de Turquia, SP.
Boota, GUZ. HIND.	*Faulkner.*

The Zea mayz of botanists is at present well known and much cultivated in all the islands of the Asiatic Archipelago, taking among several corns the next rank to rice. The Malay name for this plant is jagung, which appears to be a native word, but it is not traceable to any root. The same name is found for it in many of the other languages, and extends to the Javanese.—*Crawd. Dict. page* 237. Maize (*Zea Mays*), is the common well-known Indian corn, forming one of the most important of the grain crops, and has a greater range of temperature than the other cereal grasses. It was found cultivated for food by the Indians of both North and South America, on the first discovery of that continent, and thence derived its popular name. Maize succeeds best in the hottest and dampest parts of tropical climates. It may be reared as far as 40 degrees north and south latitude on the American continent; while in Europe it can grow even to 50 degrees or 52 degrees of latitude, some of the numerous varieties being hardy enough to ripen in the open air, in England and Ireland. It is now cultivated in all regions in the tropical and temperate zones, which are colonized by Europeans. It is most largely grown, however, about the Republics bordering on the northern shores of South America, California, the United States and Canada, the West India islands and Guiana, on the coasts of the Mediterranean, and partially in India, Africa, and Australia. We see the singular fact in Mexico of land which, after perhaps thousands of years' culture is so little exhausted, that with a very little labor bestowed on it, a bad maize harvest will yield two hundred fold profit, whilst a good crop return 600 fold. This grain adapts itself to almost every variety of climate, and is found growing luxuriantly in the low country of Mexico, and nearly equally well on the most elevated and coldest regions of the table-land in the rich valleys of the Cordilleras or the Andes, and on the sandy heights of those mountains wherever a rill of water can be brought to nourish its roots. In short, it ripens under the sun of America, in every part of both continents. Though wheat is characterised as the most nutritious food for man in all quarters of the world yet the Indian corn crop of the United States is not second in value to any product of the earth; cultivated in the middle and Eastern States, nay, even in the rich cotton-growing districts Indian corn is fast rising in importance and will soon equal in value that important commercial staple. This indigenous grain yields to that nation an annual average of five hundred millions of bushels, and has, within the last five years, attracted much attention as a life-sustaining food, more particularly at the period of Ireland's severe suffering, in 1847, and the following years. Nations, as well as statesmen and farmers, have found it an object worthy of their consideration and esteem. When due regard is paid to the selection of varieties, and cultivated in a proper soil, maize may be accounted a sure crop in almost every portion of the habitable globe, between the 44th degree of north latitude and a corresponding parallel south. Among the objects of culture in the United States, it takes precedence in the scale of cereal crops, as it is best adapted to the soil and climate, and furnishes the largest amount of nutritive food. Besides its production in the North American Republic, its extensive culture is limited to Mexico, the West Indies, most of the States of South America, France, Spain, Portugal, Lombardy, and Southern and Central Europe generally. It is, however, also cultivated with success in Northern, Southern, and Western Africa, India, China, Japan, Australia, and the Sandwich Islands, the groups of the Azores, Madeira, the Canaries, and numerous other Oceanic isles. Maize is not a favorite grain as bread-corn with the European nations, for although it abounds in mucilage, it is asserted to contain less gluten, and is not likely to be much used by those who can procure wheaten flour, or even rye bread. The large importations which were made by the English Government during the prevalence of the potato disease, brought it into more general use among some classes, and the imports for home consumption are still extensive, having been as follows in the last few years:—

	1848.	1849.
Indian corn, quarters,	1,582,755	2,249,571
,, meal, cwts.	233,880	102,181

	1850.	1851.
Indian corn, quarters,	1,286,264	1,810,425
„ meal, cwts.	11,491	

The trade in maize, or Indian corn, is totally new since 1846. The famine in Ireland in that year, and the potato rot in almost every successive year since, have now fully established it. Like the gold discoveries, the potato rot may be regarded as a providential means of effecting a great change in the condition of society. Those discoveries are not without their influence in the East, and, combined with the potato rot, they have rapidly increased the commerce between the East and West of Europe, while they are spreading broad paths between all Europe and the lands in the Southern Ocean. The imports of maize from all parts, in 1852, amounted to 1,550,000 quarters, of which about 1,100,000 quarters arrived in vessels from the Mediterranean, calling at Queenstown or Falmouth for orders. The balance consists of imports from America, France, Portugal, and also of cargoes addressed direct to a port of discharge, without

first calling off the coast for orders. The quantities received in 1851 and 1852 from the Mediterranean were as follows:—

Received from	1852. qrs.	1851. qrs.
Galatz, ...	223,000	286,067
Ibraila, ...	362,600	211,779

(Parliamentary Paper, No. 14, Sess. 1852.)

The many excellent properties of Indian corn, as a wholesome nutritious food, and the rich fodder obtained from the stalk and leaf for the nourishment of cattle, invite more earnest attention from the farmer and planter in the Colonies to its better and extended cultivation. Though the average quantity of grain from each acre in the United States is not more than thirty or forty bushels, yet it is known that with due care and labor 100 to 130 bushels may be obtained. In feeding cattle little difference is discoverable between the effects of Indian corn meal and oil cake meal, the preference rather preponderates in favor of the latter. Corn cobs, ground with the grain, have advocates, but this food is not relished, and swine decline it. Indian corn contains about the same proportion of starch as oats (sixty per cent.), but is more fattening, as it contains about nine or ten per cent. of oily or fatty ingredients The following analysis of maize is given by Dr. Samuel David, of Massachusetts :—

FLESH FORMING PRINCIPLES.

Gluten, albumen, and casein,.....	12·60

FAT FORMING PRINCIPLES.

Gum, sugar, starch, woody fibre, oil, &c...	77·09
Water,.....	9·00
Salts,.....	1·31
	100·

Professor Johnston supplies a table, which, he says, exhibits the best approximate view we are yet able to give of the average proportion of starch and gluten contained in 100 lbs. of our common grain crops as they are met with in the market. From this table I extract the following :—

	Starch, gum, &c.	Gluten, albumen, &c.
Wheat flour,.....	55 lbs.	10 to 15 lbs.
Oats,.....	65 ,,	18 lbs.
Indian corn, ...	70 ,,	12 ,,
Beans,.....	40 ,,	28 ,,
Peas, ...	50 ,,	24 ,,
Potatoes,.....	12 ,,	2⅛ ,,

The Professor remarks that the proportion of oil is, in 100 lbs. of

Wheat flour, ...	2 to 4
Oats, ...	5 ,, 8
Indian corn, ...	5 ,, 9
Beans and peas, ...	2½ ,, 3
Potatoes,...	0¼

Of the whole family of cereals, *Zea Mays* is unquestionably the most valuable for cultivation

in the United States. When the time shall come that population presses closely on the highest capabilities of American soil, this plant, which is a native of the New World, will be found greatly to excel all others in the quantity of bread, meat, milk, and butter which it will yield from an acre of land. With proper culture, it has no equal for the production of hay, in all cases where it is desirable to grow a large crop on a small surface. Although there has been much written on the Eastern origin of this grain, it did not grow in that part of Asia watered by the Indus, at the time of Alexander the Great's expedition, as it is not among the productions of the country mentioned by Nearchus, the commander of the fleet; neither is it noticed by Arian, Diodorus, Columella, nor any other ancient author; and even as late as 1491, the year before Columbus discovered America, Joan di Cuba, in his "Ortus Sanitatis," makes no mention of it. It has never been found in any ancient tumulus, sarcophagus, or pyramid; nor has it ever been represented in any ancient painting, sculpture, or work of art, except in America. But in that country, according to Garcilaso de la Vega, one of the ancient Peruvian historians, the palace gardens of the Incas, in Peru, were ornamented with maize, in gold and silver, with all the grains, spikes, stalks, and leaves; and in one instance, in the "garden of gold and silver," there was an entire cornfield, of considerable size, representing the maize in its exact and natural shape; a proof no less of the wealth of the Incas, than their veneration for this important grain. In further proof of the American origin, it may be stated that this plant is still found growing, in a wild state, from the Rocky mountains in North America, to the humid forests of Paraguay, where, instead of having each grain naked, as is always the case after long cultivation, it is completely covered with glumes or husks. It is, furthermore, a well authenticated fact, that maize was found in a state of cultivation by the aborigines, in the island of Cuba, on its discovery by Columbus, as well as in most other places in America, first explored by Americans.

Culture in the East Indies.—The growers on the hills of Nepaul reckon three kinds of maize: a white grained species, which is generally grown on the hills sides; a yellow grained one, grown in the low and hot valleys; and a smaller one, called "Bhoteah," or "Murilli Makii," which is considered the sweetest of the three, but from being less productive is not generally grown on good lands. Maize thrives best on a siliceous, well-drained, rich soil. A correspondent in Simmonds' "Colonial Magazine," vol. ii. p. 309, says the finest Indian corn he ever saw was in the Hamalayas of the Sikkim range, where the soil consists of a substratum of decomposed *mica* from the under or rocky stratum,

with a superstratum of from three to six inches of decayed vegetable matter, from leaves, &c., of the ancient forests. Throughout Hindostan, June is the usual time for sowing. In Behar, about two seers are usually sown upon a beggah; in Nepaul, twenty-four seers upon an English acre; in the vicinity of Poonah, one and a-half seer per beegah. Before the seed is sown the land is usually ploughed two or three times, and no further attention given to the crop than two hoeings. In Nepaul, where it is the principal crop cultivated, the seed is sown, after one delving and pulverisation of the soil, in the latter end of May and early part of June, the seeds being laid at intervals of seven or eight inches in the drills, and the drills an equal space apart. The drills are not raised as for turnip sowing, but consist merely of rows of the plant on a level surface. The seed is distributed in this manner with the view of facilitating the weeding of the crop, not for the purpose of earthing up the roots, which seems unnecessary. The Indian corn sowing resembles that of the *gohya* (or upland) rice, in the careful manner in which it is performed; the sower depositing each grain in its place, having first dibbled a hole for it five or six inches deep, with a small hand hoe, with which he also covers up the grain. The after-culture of this crop is performed with great care in the valleys, but much neglected in the hills especially on new and strong lands. In the former it undergoes repeated weeding during the first month of its growth, the earth being lossened round the roots, at each weeding, with the hand hoe. After the first loosening of the soil, which is performed as soon as the plants are fairly above ground, a top dressing of ashes or other manure is given. By this mode the crop gets the immediate benefit of the manure, which otherwise, from the extraordinary rapidity of its growth, could not be obtained by it. In three months from the time of sowing, the seed is ripe. The crop is harvested by cutting off the heads. In Nepaul these are either heaped on a rude scaffolding, near the cultivator's house, or, more commonly, they are suspended from the branches of the trees close by, where, exposed to wind and weather, the hard and tough sheath of the seed cones preserves the grain for many months uninjured. Cattle are voraciously fond of the leaves and stems, which are very sweet, and even the dry straw, which Dr. Buchanan surmises may be the reason why it is not more generally cultivated by the natives, as the difficulty would be great to preserve the crop. So slow is the progress of changes in the regions of India, that near Kaliyachak, though the people give all other straw to their cattle, yet they burn that of maize as unfit for fodder. In Nepaul the stalks, with the leaves attached, often twelve feet long, cut by the sickle, are used as fodder for elephants, bedding for cattle, and as fuel. The maize crop within the hills of Nepaul suffers much from the inroads of bears, which are very numerous in these regions, and extremely partial to this grain. The average return from this crop is seldom below fifty seers, ranging frequently far above it. [Transactions of "Agri.-Hort. Society, of Calcutta," vol. iv. p. 125.] Maize is increasing in cultivation in Java, and some of the Eastern islands. It is found to have the advantage there over mountain rice, of being more fruitful and hardy, and does not suffer from cold until the mean temperature falls to 45 deg. of Fahrenheit, and no heat is injurious to it. Several varieties of it are known, but for all practical purposes these resolve themselves into two kinds: one, a small grain, requiring five months to ripen, and a larger one, which takes seven to mature. In some provinces of Java it yields a return of 400 or 500 fold. Mr. Crawfurd found, from repeated trials, that in the soil of Mataram, in Java, an acre of land, which afforded a double crop, produced of the smaller grain 848½ lbs. annually.—*Simmonds, page* 283.

(5082) MAJOOM.

Majoom, Duk. Guz. Hind. Sans. Tam. | Madjoon, Turk.

An intoxicating electuary formed of ganjah leaves (*Cunabis sativa*), milk, ghee (clarified butter), poppy seed, flowers of the thorn apple (*Vern.*, Datura), the powder of the nux vomica, and sugar, sometimes also cloves; nutmegs; mace; saffron and sugar candy. It is used by the Mahomedans and Hindus, particularly the more dissolute, who take it to intoxicate, and ease pain.—*Faulkner.*

(5083) MAKLEUA. A berry called *Makleua* grows on a large forest tree at Bankok, which is used most extensively by the Siamese as a vegetable black dye. It is merely bruised in water, when a fermentation takes place, and the article to be dyed is steeped in the liquid and then spread out in the sun to dry. The berry, when fresh, is of a fine green color, but after being gathered for two or three days it becomes quite black and shrivelled like pepper. It must be used fresh, and whilst its mixture with water produces fermentation.—See Diospyros.

(5084) MAKO.

Pulidun: Gurkhi, Hind.

Solanum nigrum; and solanum rubrum. The dried black and red berries are indiscriminately sold as medicine: are also eaten fresh by the poor: the leaves are given in flatulency, and are eaten as a vegetable in dropsical swelling of the hands and feet: are also pounded with ginger to rub the hands and feet, do not seem to be poisonous in India.—*Gen. Med. Top. p.* 145.

(5085) MADRAS.

SEA CUSTOM HOUSE.
Madras, 5th December 1856.

Collector, Sea Customs.

(5086) MALABAR CREEPER.—IPOMEA TUBEROSA.

(5087) MALABAR NIGHT-SHADE.—BASELLA RUBRA.

(5088) MALABATHRUM, a name which occurs frequently among the writings of the ancients, and which was applied to a leaf imported from India, whence it was likewise called φύλλον Ἰνδικόν, and also simply Folium. It was employed by them both as a medicine and as a perfume. From it there was prepared both an oil and a wine by maceration of the leaves in these menstrua. Many fabulous statements accompany the earliest accounts, as that of Dioscorides, by whom it is stated that by some they are thought to be the leaves of the Indian Nard; that they are moreover found floating on Indian marshes, and that they grow without roots (lib i., c. 11), and that (lib. ii c. 10) it is by feeding on them that the animal affording the Onychia or Unguis Odoratus of the ancients, becomes aromatic. In the works of the Arabs Saduj is given as the synonyme of *Malabathrum*; and Saduj, both in Persian works and in India, is applied to Tej-Pat, or the leaf of the Tej, which is a species of *Cinnamomum*, *C. albiflorum*, growing in the dense forests of the valleys of the Himalaya, which extend from Rungpore to the Deyra Doon in 30° N. lat. Dr. Hamilton found the same name applied to a very nearly allied species, the *C. Tamala*. Both species most probably yield the leaves which were so highly esteemed in ancient times, and are still as extensively employed in eastern countries, and may be found in every Indian bazaar under the names of Tej, or Tej-Pat, or by the Arabic name of Saduj-Hindee. They are analogous in all respects to bay-leaves produced by the *Laurus nobilis*, and are in fact the bay-leaves of India. The name *Malabathrum* no doubt is derived from Tamala-putra, or Tamala-leaf, as was first indicated by Garcies: "Appellant autem Indi folium *Tamalapatra* quam vocem Græci et Latini imitantes corrupte *Malabathrum* nuncuparunt." These are brought from the interior of almost inaccessible forests, and necessarily stripped from the branches for the facility of carriage; hence most probably originated the fables with which their early accounts are accompanied.—*Eng. Cyc.*

(5089) MALACCA CANES. The late Dr. Griffith believed these Canes to be produced from the *Calamus Scipionum*, the *Heotan* of Cochin-China. They do not occur about Malacca, but are imported from Siak, on the opposite Coast of Sumatra. Some of them are simply mottled or clouded, others of a brown colour, in consequence, it is said, of their having been smoked. The most slender specimens, with the longest internodes, are the most valued.—*Seeman.*

(5090) MALACHITE. The mines of Siberia, at Nichne Tagilsk have afforded great quantities of this ore. A mass partly disclosed measured at top 9 feet by 18 feet; and the portion uncovered contained at least half a million pounds of pure malachite. Other noted localities are Chessy in France, Sandlodge in Shetland, Schwartz in the Tyrol, Cornwall, Australia, and the island of Cuba. This mineral receives a high polish, and is used for inlaid work, and also ear-rings, snuff-boxes, and various ornamental articles. It is not much prized in jewellery. Very large masses are occasionally obtained in Russia, which are worked into slabs for tables, mantel pieces, and vases, which are of exquisite beauty, owing to the delicate shadings and radiations of colour. In the Great Exhibition of 1851 there were magnificent specimens of this material in the shape of doors and vases sent thither by the Emperor of Russia. At Versailles there is a room furnished entirely with tables, chairs, &c., wrought in malachite, and the same are to be found in other European palaces. At

Nichne Tagilsk, a block of malachite was obtained weighing 40 tons. Malachite is sometimes passed off in jewellery as turquoise, though easily distinguished by its shade of colour and much inferior hardness. It is a valuable ore when abundant, but it is seldom melted alone, because the metal is liable to escape with the liberated volatile ingredient, carbonic acid.—*Eugl. Cyc. page* 134.

(5091) MALDY. A fabric made at Maldah of a mixture of silk and cotton, very durable and which washes well. It is exported through Sikkim to the North West provinces and Tibet.—*Hooker, Vol.* II *p.* 251.

(5092) MALJHUN, OR MALOO CLIMBER, BAUHINIA RACEMOSA (LEGUMINOSÆ). Along the forests of the Sewaliks and the hot valleys of the Himalayas, from the doons of the North-West to the valley of Assam, may be seen a magnificent climber, called *Maljhun* or *Maloo*, with a two-lobed leaf. Of this, Dr. Royle observed, in his 'Himalayan Botany,' p. 184, that *Bauhinia racemosa* hangs in elegant festoons from the tops of lofty trees, which one is at a loss to conceive how, from the distance of its root from the stems, it could ever have ascended; but occasionally a half-killed tree displays the mode of its progress, and indicates the destruction it must have created in the forest. With the bark of this plant, which, when stripped off, is of a reddish-brown colour, the natives of these mountains make ropes. It was one of those to which Dr. Roxburgh turned his attention, and which has been frequently noticed by travellers in the Himalayas. Capt. Huddleston states that the stems are usually cut in July and August; the outer bark being stripped off, is thrown away, and the inner is used for ropes, as wanted, by being previously soaked in water, and twisted when wet. It is also said to be boiled and beaten with mallets, which renders it soft and pliable for being twisted into ropes and strings for charpaes. Though the fibre makes very strong ropes, it is not over-durable, and rots if kept constantly in water. Though not collected for sale, it is very abundant all along the foot of the mountains. Major Swetenham, formerly of the Bengal Engineers, on the 11th of November, 1840, despatched to the late Mr. Thomason some of the fibres of the Maloo creeper, and a specimen of a rope made from it, which he obtained from the valley of the Jumna River within the hills. He describes it as making strong coarse ropes, which he had found to answer well for suspension bridges, though he was unable to say how long they would bear exposure to moisture, for "they had been in use only for two or three years, and iron suspension bridges substituted." Specimens of the fibre, and rope made from it, were sent to the Exhibition of 1851, from Bhagulpore, and called *Patwa* or *Mawal* fibre.

Bauhinia scandens.—Similar in properties and uses to the above, is another species of the same genus, of which we find the following notice in the 'Journal of the Agri-Hortic. Society,' vi. p. 185. Specimens of the fibre of *Bauhinia Scandens*, and cloth made therefrom, were sent to Major Jenkins by Major Hannay, who mentions that the fibre is used by the Nagas. The plant, Major Jenkins adds, is not uncommon about Gowhatti. It was recognized by Dr. Falconer, from a few leaves forwarded by Major Jenkins, to belong to *Bauhinia scandens*, a common species in Silhet. Captain Thomson having tested this fibre, reports on it to the following effect: "The line made from the fibre sent by Major Jenkins, sustained for forty-five minutes, 168 lb., having stretched six inches only in three feet, and therefore is about the same strength with our best *Sunn* Hemp. But, whether from the mode of preparation or the nature of the material, is so harsh and stubborn, and the fibres stick so close together, that the heckles tear it to pieces, and injure its strength." Dr. Buchanan, in his 'Survey,' mentions both these species as used for many of the same purposes.—*Royle Fl. p.* 295.

(5093) MALKUNGUNEE, OR STAFF TREE OIL.—CELASTRUS PANICULATA. Oleum Nigrum.—Valuluvy tylum.

Valuluvy yennai, TAM. | Malkungunee ka tael HD.
Bavungie noona, TEL. | Vaylarie tylum, TAM.

An empyreumatic oil obtained by the destructive distillation of the seeds of this Celastrus, either alone or in combination with other ingredients. It was much used in the treatment of Beri-beri, Malcolmson's Essay p. 312.—*M. E. J. R.*

(5094) MALMSLEY. A very rich luscious species of Madeira wine, made from the grapes grown on rocky grounds exposed to the full influence of the sun's rays, and allowed to remain on the vine till they are ripe.—*McCulloch. Faulkner.*

(5095) MALONI BAPCAI, seed of a small plant found about Ajmeer; tasteless; has a fine scent: is of a warm nature, a dram is given in medicine used externally with other medicines to cure the itch.—*Med. Top. of Ajmeer, p.* 127.

(5096) MALOPE GRANDIFLORA, a malvaceous plant growing in India, which yields fibres.

(5097) MALOPE. MALVACEÆ. These are very beautiful annual plants, and grown readily from seed at the commencement of the rains the colour of flowers purple, and violet, the plant grows to the height of seven or eight feet and is better adapted for a shrubbery than the flower garden.—*Riddell.*

(5098) MALLOW, KHITMEE. Khungee. Malva. Root of Malva sylvestris or Mauritiana. In making the Compound decoction of Mallow,

the dried capsules of the okra, Hibiscus esculentus, may be substituted.—*Beng. Phar. p.* 277.

(5099) MALLOW WORTS. MALVACEÆ. A family of plants, extremely numerous in species many of which are employed in different countries as sources of commercial products, the genera *Malva*; Hibiscus: Sida; Althœa; Lavatera; Urena and Gossypium, yielding tenaceous fibre suited for cordage and other purposes.

(5100) MALPIGHIA COCCIFERA. MALPIGHIACEÆ. A small stunted shrub, with leaves resembling the box; common in gardens.

(5101) MALPIGHIA HETERANTHERA. A handsome shrub of the genus malpighia, with leaves like the holly, and nearly related to the Barbadoes cherry, is occasionally cultivated in European gardens.

(5102) MALPHIGIA PUNICIFOLIA. BARBADOES CHERRY. An ornamental shrub introduced from the West Indies. Hort. Garden, 25.

(5103) MALT.

Mout, DUT.	Maltum, LAT.
Mal, Bledgerme, FR.	Solod, RUS.
Maly, GER.	Cebada retonada o entallecida, SP.
Malto, IT.	

The term malt is employed to designate grain, which, being steeped in water, is made to germinate to a certain extent, after which the process is checked by the application of heat. This evolves the saccharine principle of the grain, which is the essence of malt. Rice, and almost every species of grain, has been used in malting; but in Europe, and especially in England, malt is almost entirely prepared from barley. It is the principal ingredient in the manufacture of beer, and is little used except in brewing and the distillation of spirits.—*McCulloch. Faulkner.*

(5104) MALTHA, SEA WAX. A solid, whitish, inflammable, vegetable substance, not unlike tallow, and may be impressed with the nail. It swells when heated, and on cooling assumes the consistence of white cerate. It affords a better light than petroleum, and emits a less disagreeable smell. It is found on the surface of the Baikal lake in Siberia, at the foot of the mountains of Bucktiari in Persia, and other places.

(5105) MALVA CUNEIFOLIA. This is an annual found growing in single plants here and there all over the Burmese country, but chiefly in the jungle. It affords a strong yellowish white fibre, but from the scattered way in which it grows in a wild state, it would be difficult to collect it in any quantity.—*McClelland.*

(5106) MALVA MAURITIANA.

Kungee ke pat, LAT.

The seeds of this are brought from Hydrabad. It is cultivated in most parts of this country, may be used.

(5107) MALVA MINIATA. This is an extensive genus of plants of easy culture and every variety of colour, easily propagated by seed, cuttings, or dividing the suckers.—*Riddell.*

(5108) MALVA ROTUNDIFOLIA, L. is likewise cultivated in India. V. Roxb. vol. ii. p. 181.—*O'Shaughnessy, page* 214.

(5109) MALVA SYLVESTRIS. MARSH-MALLOW.

Khabazee and Anjil, ARAB. | Khitmie, PERS.

The seed, towdric.—*O'Shaughnessy, p.* 214.

(5110) MALVA TILLÆFOLIA is a straggling annual during the rains and is found widely dispersed in Burmah. The fibre of this plant resembles jute.—*McClelland.*

(5111) MALVACEÆ. As many plants have flowers and seed-vessels which closely resemble the Mallow, they have been united by botanists into a natural family of plants, which they have called *Malvaceæ*, or Mallow-worts. Some other families, such as the *Tiliaceæ* or Linden Tribe elsewhere described, and the *Sterculiaceæ* and *Byttneriaceæ*, also noticed, having also a considerable resemblance to each other and to the *Malvaceæ*, have been further grouped into a larger class which has been called *Malavales*. These groupings are interesting, inasmuch as they bring together, though in these different families, a number of plants which resemble each other in properties; for the greater number of the species not only abound in mucilage, but their barks in fibres which are manufactured into cordage. Of these, numerous instances are mentioned in these pages, but still more will probably remain to be enumerated and reported on by subsequent observers; and, therefore, colonists in tropical countries may search among these for fibre-yielding plants with considerable certainty of finding many possessed of very valuable properties. The family of Malvaceæ or Mallow-worts is extremely numerous in species, which abound chiefly in tropical parts of the world in the form of trees and shrubs, though species, as the Mallow and Marsh Mallow, do extend to temperate climates. The known fibre-yielding plants belong to the genera *Malva, Hibiscus, Sida, Althœa, Lavelera, Urena*, &c.; besides *Gossypium*, the genus yielding Cotton. Of these many are employed in different countries for yielding fibre for cordage and for other purposes. *Royle Fib. Pl. p* 254. *Urena lobata* and *U. sinuata*, two weeds also belonging to the family Malvaceæ the one called *bun-ochra* and the other *kunga*, are common in most parts of India, also abound in strong fibre and a tolerable fine substitute for Flax.

If the common Mallow (*Malva sylvestris*, &c.,) of Europe, or the Marsh-mallow (*Althæa officinalis*), are examined, it will be found that they abound in fibre; others of these genera are valued for their fibres in different countries. as *Malva crispa* is said by Cavannilles to have its fibre separated in Syria, and *Althæa cannabina*, is sometimes so employed in the South of Europe; so *Lavatera arborea*, or Tree Mallow, will be found to abound in fibre.—*Royle, Fib. Plants.* The *Malvaceæ*, or *Mallow-worts*, are a large natural order of Exogenous Plants, the distinguishing marks of which are polypetalous flowers, monadelphous stamens, unilocular anthers, and a valvate calyx. They also have alternate leaves, the hairiness of which, if present, is usually stellate; and conspicuous stipules. A large proportion of the order consists of herbaceous or annual plants, inhabiting all the milder parts of the world, but much the most plentiful in hot countries, where alone a comparatively small number of species become trees. In many cases they are remarkable for the large size and beautiful colours of their flowers, which are however fugitive, expanding for a single day only; but the great number of them and the regularity of their succession during the flowering season make this of little importance. Among the very numerous species several are of essential service to man. As emollients they are well known in medical practice, the Marsh-Mallow (*Althæa officinalis*) being one of the most useful among this kind of remedial substances, and a large proportion of the whole order being capable of supplying its place. The hairy covering of the seeds of the various species of *Gossypium* forms the raw cotton so important to manufacturers. *Malva tricuspidata* is used by the negroes in the West Indies as a substitute for soap. The seeds of *Hibiscus abalmoschus* are warm and musky, and are employed in perfumery as a substitute for musk; those of *H. esculentus* form the ochra, so much used in hot countries as a mucilaginous ingredient in soups. A few species are acid, especially *H. sabdariffa*. Finally the tenacious fibres procured from the inner bark of many kinds of Malvaceous Plants form a good description of cordage. *H. elatus* and *H. tiliacea*, and several kinds of *Sida*, are principally used for this purpose. The order is related to *Sterculiaceæ* and *Byttneriaceæ*. There are 37 genera and 1000 species. The only modern systematical account of the genera and species of the order is to be found in the first volume of De Candolle's 'Prodromus;' but the genera have been since constructed upon principles so much more precise, and the number of species has been so very considerably increased, that this enumeration is of little use at present. There is a good account of Indian species in Wight and Arnott's 'Prodromus Floræ Peninsulæ Indiæ Orientalis;' of Brazilian species in Auguste de St. Hilaire's 'Flora Braziliæ Meridionalis;' and of Mexican kinds many are described in the various volumes of the 'Linnæa.' A few African species are also to be found in Guillemin and Perrottet's 'Flora Senegambiæ,' vol. i.—*Eng. Cyc.*

(5112) MAMEERA MAMEERAN, are of two different kinds in the Lahore bazaar, the one from Cashmere, the other from China, called Khutai (Scythea). The latter is officinal all over the East, being much used by the Hakims, who deem this root to be a specific in ophthalmies; but, they say, that the genuine drug is seldom to be met with, and this I believe, as it has many substitutes. (Chelidonium majus and Glaucum.) Dr. Royle affirms Ranunculus ficaia or ficaria to be the plant from which the Cashmerean mameera is produced. Both, sorts are used, in general externally, and in composition with other dugs, are applied to the eyes as a dry collyrium.—*Honigberger, p.* 304.

(5113) MAMMALIA, MAMMALS, a term employed by Linnæus to designate those animals which suckle their young, and which seems preferrible to the term Mammiferes generally used by the French zoologists. Mammals are vertebrated animals whose blood is red and warm, and whose system of circulation is double; whose fœtus, in most species, is nourished in utero by means of a placenta; whose young, when born at the proper period, give signs of life at their birth, and are in a state of nature, afterwards fed with milk secreted by the mammæ of the mother till they are old enough to procure their food, or to have it supplied from other sources. Linnæus, who makes the *Mammalia* the first class of the Animal Kingdom, gives the following definition:—Heart with two auricles and two ventricles; blood warm, red; lungs respiring reciprocally; jaws incumbent, covered: armed with teeth in most; penis intrans, viviparas, lactiferas; senses—tongue, nostrils, eyes, ears, papillæ (touch); covering—hairs, &c.; support (fulcra)—four feet, except in those which are entirely aquatic, in which the posterior feet are bound together (compedes) into the fin of the tail; a tail in most. This class Linnæus divides into orders, principally resting on the bases of dentition. His name for the incisor teeth is Primores; for the canine or cuspidate-teeth, Laniarii: and for the back or grinding teeth, Molares. The orders, which are six in number, are comprised in three sections, depending on the nature of the extremities;—1. The *Unguiculata*, containing the orders *Bruta*, *Glires*, *Primates*, and *Feræ*. 2. The *Ungulata*, comprising the *Belluæ* and *Pecora*. 3. The *Mutica*, consisting of the order *Cete* (Whales) only. 1. The *Primates* consist of the genera *Homo*, *Simia*, *Lemur*, and *Vespertilio*. 2. The *Bruta* comprises the genera *Elephas*, *Trichechus*, *Brachypus*, *Myrmecophaga*, *Manis*, and *Dasypus*.

3. Under the *Feræ* are arranged the genera *Phoca*, *Canis*, *Felis*, *Viverra*, *Mustela*, *Ursus*, *Didelphis*, *Talpa*, *Sorex*, and *Erinaceus*. 4. The *Glires* embrace the genera *Hystrix*, *Lepus*, *Castor*, *Mus*, *Sciurus*, and *Noctilio*. 5. The *Pecora* comprehend the genera *Camelus*, *Moschus*, *Cervus*, *Capra*, *Ovis*, and *Bos*. 6. To the *Belluæ* belong the genera *Equus*, *Hippopotamus*, *Sus*, and *Rhinoceros*. 7. Under the order *Cete* are arranged the genera *Monodon*, *Balæna*, *Physeter*, and *Delphinus*. The following Table exhibits the geographical distribution of the species of *Mammalia* contained in the collection of the British Museum, one of the most extensive collections in the world:—

Mammalogy is the science which has for its object the study and classification of animals with mammæ, or beasts, that is to say, Man, and Quadrupeds properly so called, including the Quadrumanous Animals and Whales. The objects of this science are numerically much less than those which constitute the other classes of animated beings; their bulk, as compared with that of the others, is generally speaking of greater volume, and their structure is more readily laid open by the knife of the zootomist; whilst, with the exception of those passages by which nature gradually passes from one form to another, their differences are more strongly marked. The habits too are better known, and consequently they afford materials for classification capable of a comparatively certain arrangement. To a certain extent the knowledge of *Mammalia* and their nominal distinctions, as regards their habits and economic uses, must have been of the earliest date. The Holy Scriptures abound with passages to confirm this statement, if indeed it needed confirmation. Ancient monuments too, long anterior to the times of the Greeks and Romans, speak the same language. When we come down to the time of Aristotle, we find that the science had not proceeded further than a knowledge of the external and internal structure of these animals, without any attempt at a systematic arrangement of them. If we descend lower, we find the science in the same state whether we consult the works of Pliny or of the other ancient writers who followed Aristotle. Our limits will not permit us to do more than allude to the authors, and they were not few, who entered upon this branch of the science after Ray. Of these Seba may be considered one of the principal, and his work is justly appreciated for the number, and generally speaking for the accuracy of the well-executed plates which illustrate his voluminous work. But there then arose one who was eminently distinguished from the crowd of zoological authors. Linnæus, an outline of whose system is given above, fixed the science upon a basis which his penetrating genius immediately saw was the secure one. He may be said to have invented a language admirably adapted to the wants of that science; and it is in this department that the great Swedish naturalist shines pre-eminently as a zoologist. In vain was the splendid genius of Buffon arrayed against him and his pupils; in vain did Klein, who seemed to live for no other purpose than to attack the Swede, publish his 'Quadrupedum Dispositio brevisque Historia Naturalis' (1751), wherein he separated the *Mammalia* into two groups, the Ungulated and the Unguiculated, each consisting of five families; in vain did Brisson (1756) publish his 'Animal Kingdom divided into Eleven Classes,' containing 18 orders and 42 genera, some of the latter well defined and still admitted; the philosophical system of Linnæus daily gained ground, and at length became almost the universal language of zoology.—*Eng. Cyc.*

Notices of the more important of the Mammals of Southern and Eastern Asia will be found entered under their several heads, but we give here a Catalogue of the Species of Mammalia found in the Southern Mahratta Country; with their Synonimes in the native languages in use there, —By Mr. WALTER ELLIOT, of the Madras Civil

Service, and October in the Madras Literary Society's Journal, July 1839. The district of India, in which the animals contained in the following list were procured, is a part of the high table-land towards the south of the Dekhan, commonly called the Southern Mahratta Country, and constitutes the British zillah of Dharwar. It ought, likewise, geographically speaking, to include the small province of Sunda, which, according to the political arrangement of the country, is placed under the zillah of Canara, in the presidency of Madras. The general boundaries are the rivers Kistnah and Bhima on the north and N. E.: the Tumbhoodra river on the south; the Nizam's territory on the east, and the Syhadri range of mountains on the west The latter are generally called the Ghats; a term which however properly applies only to the passes leading through them. The general face of this tract is much diversified, and affords a great variety of elevation and of geological structure, thereby materially affecting the distribution and the habitat of the different species of animals existing within its limits. The whole of the western portion is a thick forest, extending from the outskirts of the mountainous region of the Ghats to their summits, and clothing the valleys that extend between their different ridges. It abounds with the teak and various other lofty forest trees, festooned by enormous perennial creepers. The bamboo forms a thick and luxuriant underwood in some places, while others are entirely open, and the banks of many clear and rapid streams flowing through it, abound with the black pepper plant, the wild cinnamon and other oderiferous shrubs. Portions of this forest are often left entirely untouched by the axe or knife, forming a thick impervious shade for the growth of the black pepper, cardamom and Mari palm—(*Caryota urens*). These are called *kans* and are favourite resorts of wild animals. To the east of the regular forest lies a tract called the *Mulnad*, or *rain-country* (though the natives of the plains often include the *jhari*, or *forest*, under the same denomination), in which the trees degenerate into large bushes, the bamboo almost entirely ceases, and cultivation, chiefly of rice, becomes much more frequent. The bushes consist chiefly of the *karunda*, the *pallus*, &c. It abounds in tanks and artificial reservoirs for purposes of irrigation. East of the Mulnad is a great extent of alluvial plain, producing fine crops of wheat, cotton, maize, millet, &c. [Holcus sorghum, Panicum Italicum, Cicer arietinum.] And on the Nizam's frontier are found a succession of low dry hills, with tabular summits, often rising in abrupt scarped precipices, and intersecting and traversing the plains in various directions. They are clothed with low thorny jungle of *babul* and *acacia*, and their bases, and the valleys between, composed of a light sandy soil, are cultivated with millet vetches, &c. [Panicum spicatum, Panicum miliare, Phaseolus max, Phaseolus mungo, &c.] The first or mountainous division consists chiefly of micaceous, clay, and other schists, which to the northward are succeeded by basaltic or trap formation. The Mulnad is composed of undulating clay-slate hills, which become covered with basalt to the north. This trap formation extends in a slanting direction from S. W. to N. E. nearly coinciding with a line drawn from Sadasheaghur on the coast, to Beejapoor and Sholapoor—and, what is remarkable, is almost coincident with that marking the separation of the two great tribes of the population using totally distinct languages,—the Mahrattas and Canarese. The hills to the N. E. and E. are all of primitive sandstone sometimes resting on schists, sometimes immediately on granite, which latter is the rock nearest the surface in the central and eastern plains. But a well defined range of hills to the S. W., called the Kupputgud, is entirely composed of micaceous and clay slates, resting on granite. The hills more to the N. and N. W. are basaltic. The extensive plains lying between these different lines of hills and eminences are composed of the rich, black mould, called *regur*, or cotton ground, resulting from decomposed basaltic rocks. To the N. E. a considerable tract of limestone is found, resting on the sand stone, about Bagalcote, Badami, Hungund, Mudibihal, &c. The distribution of species throughout these different tracts is shown in the following table: those marked are confined to one tract only.

Distribution of Species.

Common to all.	Mountain Forest.	Mulnad.	Black Plains.	Sandstone Hills and red sandy soil.
Simia radiatus	Simia Entellus	Cynopterus Marginatus	Canis Lupus	Simia Entellus (rare)

(5114) *Simia* (*Macacus*) *radiatus.*—*Cercocebus Radiatus*, Geoff.

Koti, Munyga, Munga,	Can.	Bandar, Dek. Makada, Mah. Kerda, do. of the Ghats.

This species abounds over the whole country, sometimes inhabiting the wildest jungles, at others living in populous towns, and carrying off fruit and grain from the shops of the dealers, with the greatest coolness and address.—*Elliot M. L. S. J. July* 1839, *p.* 95.

(5115) *Simia* (*Semnopithecus*) *entellus.*—*Cercopithecus entellus*, Geoff.

Moosya, Can. Langur, Dek.	Wanur, Mah.

The black-faced monkey of Europeans,—Abounds more particularly in the forests, where its loud wild cry is particularly striking. They are both useful and troublesome to the sportsman, who may often judge by their agitation and chattering of the vicinity of some beast of prey; while he himself is apt to be assailed in a similar manner when trying to steal upon the more timid kinds of game. The species is celebrated in Hindu mythology, for having, under their leader Hanuman, assisted the hero and demi-god Rama, the first Hindu conqueror of the forests of Southern India, as related in the Ramayana. The *Entellus* appears to want the check pouches characteristic of *Semnopithecus*. An adult male measured, from muzzle to insertion of tail, 1 foot 10½ in.—length of tail alone 3 feet 2½—height from heel to crown 3 feet 2½—weight 22 lbs.—do. of an adult female 18 lbs.—*Elliot M. L. S. J. July* 1839, *page* 95.

(5116) *Pteropus edulis medius.*—*Pteropus Medius*, Temminck; *Monog. de Man.* 1. 176.

Toggal Bawli, Can. Sikatyelle, Do. of the Wuddur caste.	Guddal. Dek. Barbagal, Do.

The flying-fox of Europeans. Its flesh is esteemed good eating. The tongue of this animal is remarkable, being covered with large papillæ, pointing backwards, and each one terminating in a brush or collection of bristly points. Length of the male, 12 to 13 inches—weight 29oz—of a female, 20 oz. Expanse of wings upwards of 4 feet. When disturbed during the day, they fly slowly round and round, with a low screaming noise, and soon settle again; hovering for a moment over a bough, they catch suddenly with the claw on the angle of the wing, and, allowing the body to drop, they swing with a single hold. They vary considerably in shade and colour.—*Elliot. M. L. S. J. July* 1839.

(5117) *Pteropus* (*Cynopterus*) *marginatus*, Fr. Cuvier.—*Pteropus marginatus*, Temminck; *Monog. de Mam*, I. 202. Length, 4½ inch. Weight, 2oz. a male. The dentition agrees with the statement of Fr. Cuvier, which he adopts as the character of his genus *Cynopterus*. Incisors $\frac{4}{4}$ canines $\frac{1}{1}$ $\frac{1}{1}$ molars $\frac{4}{5}$ $\frac{4}{5}$ = 30; is somewhat rare; found in clusters on the folded leaves of the plantain, the palmyra, &c.—*Elliot M. L. S. J. July* 1839.

(5118) *Vespertilio* (*Megaderma*) *carnatica*? —New species? *M. lyra.*

General name for all bats, Kankapeli, Can.	Shamgidar, Shab parak, Dek.

This species differs from the dentition commonly assigned to *Megaderma*, in having incisors $\frac{2}{4}$ canines $\frac{1}{1}$ $\frac{1}{1}$ molars $\frac{3}{5}$ $\frac{3}{5}$=24; whereas the molars according to the Geoffroy are $\frac{4}{5}$ $\frac{4}{5}$. Above, mouse colour; beneath, paler. Nasal appendage, large, oblong, reaching to the base of the ears, with a plait or fold down in the centre. Oreillon cordate, the anterior lobe high and pointed, the posterior rounded; the muzzle truncate, the under lip cleft. Four mammæ. Female generally larger. Temminck states that the females and young of some bats live apart from the males at certain seasons, which may account for this. Mon. de mam. Tom. ii. p. 5.

	Female.	*Male.*
Length.....	3½ inches	3 inches.
Expansion of wings.	19½	18
Ear (behind),.....	1 2/10	
Ear (before),.....	1 4/10	
Carpus	2½	
Tarsus, ...	1-3½10ths.	
Head,.....	1½	
Additional length of the interfemoral membrane,	1½	
Weight,.....	1oz. 10drs.	1oz. 3drs. 10g.

These were the largest dimensions ascertained from 14 females and 7 males, obtained at various times. They are common in the Mulnad, in old temples, caves, &c.

(5119) *Vespertilio* (*Rhinopoma*) *Hardwickii.*

	Male.	Female.
Weight...	10 drs.	8 drs. 13 grs.
Length of body,.....		2 6/10 inches,
——— tail.....		2 5/10
		5 1/10
——— carpus		2 4/10
——— tarsus		2 5/10
Expanse of wings...		13.

This is probably the species already described by General Hardwicke, but the means are not at hand of verifying his description. The species has the muzzle long, thick, truncated and surmounted with a small leaf. Oreillon oblong, bi-acuminated; forehead concave, with a fossa or channel running down the centre. The nostrils are placed in the truncated plane of the muzzle, being covered with a membrane slit transversely, and with a small round puncture in the middle of the slit. By means of this apparatus the animal is enabled to open or shut its nostrils at pleasure. The leaf-like process rises from the same plane of the muzzle. Found in old ruins to the eastward of the province.

(5120) *Rhinolophus*, Geoff. This, and the two following species, seem to form a subdivision of the section *Rhinolophus* (Geoffroy), differing in the number of teeth and having in common a remarkable peculiarity common to all, not included in his specific characters, which may be described as a circular cavity, or sac, behind the nasal crest. This cavity the animal can turn out at pleasure, like the finger of a glove; it is lined with a pencil of stiff hairs, and secretes a yellow substance like wax. When alarmed, the animal opens this cavity and blows it out, during which it is protruded and withdrawn at each breathing. Temminck notices it under the name of a syphon, or purse in *R. Insignis* and *Speoris*. Dentition, incisors 2/4; canines 1/1 1/1; molars 5/5 5/5 28; whereas in Geoffroy's group the molars are 5/5 5/5, and the total number 30. But Temminck makes them vary from 4/5 to 5/6. The upper incisors are distant, placed near the canines and triangular, broad at the edge and sloping to the root, the lower ones are close together, crenelate at the edge, each having three points. In all other respects, the characters are the same as *Rhinolophus*. Nose furnished with a complicated crest. Ears distinct, marked with transverse distinct wrinkles. Interfemoral membrane large. Warts on the pubes.—*Elliot M. L. S. J. p.* 98. *July* 1839.

(5121) *Rhinolophus speoris ?—R. Crumenifere*, Peron.—*R. Marsupialis*, Geoff.—*R. Dukhunensis*, Sykes. Ears large, erect, acuminate, rounded to the base. Muzzle short, crest very complicated, consisting of a simple transverse membrane, or leaf extending between the eyes, behind which is the circular sac. In front is a cavity, in which are pierced the complicated nostrils, and surrounded by another smaller membrane; the upper portion next the frontal leaf thick and fleshy, the lower, above the lip, fine. On either side without this are three smaller parallel membranes or fringes, reaching from the eyes downwards. Body short thick, of a light mouse colour. Interfemoral membrane, narrow, square, including the tail, which consists of about four joints, the half of the last joint being free at the point. Pubes naked, large, with one or two warts. Two pectoral mammæ, two inguinal. Whether the latter are false or real is doubtful. It has been said they have no lacteal glands, but I have constantly remarked them, and that they are smaller in the young female. Females with the frontal sac less developed. On a comparison of about 18 specimens, the measurement of the largest was—

	Male.	*Female.*
Length.....	2 3/10 inches...	2 2/10
——— of tail.....	1	... 1
Total.....	3 3/10	3 2/10
——— of exserted portion of tail.....	1½ 10ths.	
——— of ear.....	6/10	
——— of carpus.....	2	
——— of tarsus	9/10	
Expansion of wings.....	13.....	12½
Weight.....	6 drs. 13 grs.	6 drs.

Found in old buildings, wells, &c. The *R. Dukhunensis* of Sykes is said to differ from *R. Speoris* in the length of the carpus, but in Temminck, Monog. de Mam. T. 11. p. 17, the fore arm is stated to be shorter than the whole length, and the difference of colour is not sufficient to constitute a specific difference.—*Elliot, M. L. S. J. July* 1839.

(5122) *Rinolophus Murinus.*—New Species. Ears large, erect, rounded: muzzle short, with a tranverse frontal leaf or membrane and the sac behind it as the last, and in front a simple membrane round the nostrils. Body short, and thick. Interfemoral membrane large,

including the tail, all but the extreme tip. Pubes small covered. Mammæ as in the preceding, colour dusky brown, paler beneath.

Male.—Length $1\frac{9}{10}$; tail $1\frac{9}{10}$—$3\frac{1}{10}$; ear $\frac{7}{10}$; carpus $1\frac{6}{10}$; tarsus, barely $\frac{8}{10}$; expansion of wings $10\frac{1}{2}$; weight 4 drs. 20 grs.—The sexes nearly alike.—*Elliot, M. L. S. J. July* 1839.

(5123) *Rhinolophus fulgens.*—New Species. This resembles the last in every respect, but the membranes of the crest are more developed. Color a bright fawn above, and golden beneath. Membrane of the wings blackish.

Length $1\frac{9}{10}$; tail $\frac{9}{10}$—$2\frac{8}{10}$; ear $\frac{7}{10}$; carpus $1\frac{6}{10}$; tarsus barely $\frac{6}{10}$; expansion of wings $10\frac{1}{2}$; weight 4 drs. 24 grs.

Very rare. The above is the description of an adult male.

It cannot be identified with the *R. larvatus* of Horsfield, which it resembles in colour, because it (the *Larvatus*) has the complicated crest and dimensions of *Speoris.*—*Elliot, M. L. S. J. July* 1839.

(5124) *Taphozous* Of this only one specimen was obtained of which the description has been lost.—*Elliot, M. L. S. J. July* 1839.

Vespertilio Proper.—Two small species are common, but neither of them have been identified. —*Elliot, M. L. S. J. July* 1839.

(5125) *Vespertilio*—Ears small, sub-triangular, shorter than the head; oreillon oblong, rounded, colour above pale dusky brown, beneath lighter. Length 2 inches; tail $\frac{7}{10}$—$2\frac{7}{10}$; carpus $1\frac{3}{10}$; expansion of wings 10 inches.—*Elliot, M. L. S. J. July* 1839.

(5126) *Vespertilio*—Smaller than the last. Ears larger, rounded, nearly as long as the head. Oreillon curved and rounded at the end. Colour dark brown above and below. Length $1\frac{9}{10}$; tail $\frac{7}{10}$—$2\frac{1}{10}$; carpus 1; expansion of wings $7\frac{3}{4}$. —*Elliot, M. L. S. J. July* 1839.

(5127) *Sorex Indicus*, Geoff.

Sondeli, Can. | Chachundar, Duk.

(5128) *Ursus* (*Prochilus*) *labiatus.*—*Ursus labiatus*, Blainville.

Kaddi, Karadi, Canarese. | Reech, Dukhani.
Aswal, Mahratta. |

The peculiar dentition of this animal, distinguishing it from Gen. *Ursus*, has been remarked by Colonel Sykes. There are never more than 4 incisors in the upper jaw. I possess several crania, one of them with the milk teeth just giving way to the adult ones, all agreeing in this peculiarity. Their food seems to be black ants, termites, beetles, fruit, particularly the seed of the *Cassia Fistula*, of the date tree, &c., honey. When pursued, they carry their cubs on their back. In 1333 a bear was chased and killed having carried her two cubs in this manner, nearly three miles. It appears to be a long-lived animal. Instances are known of their living in a state of captivity for 40 years.—*Elliot M. L. S. J. July* 1839.

(5129) *Lutra Nair.*—Fr. Cuvier.

Nirnai, Can. (literally "water dog.") | ally "water dog.")
Datwai bekk Do. of the Wuddar tribe. | Hud or Hada, Mah. of the Ghats.
Pani kutta, Duk. (liter- | Jalmanus and Jalmanjar, Mah.

Elliot, M. L. S. J. July 1839.

(5130) *Canis Familiaris, (wild variety).*—*Canis Dukhunensis* of Sykes.

Jungli Kutta, Duk.

The wild dog was not known in the Southern Mahratta Country until of late years. It has now become very common. The circumstance of their attacking in a body and killing the tiger, is universally believed by the natives. Instances of their killing the wild boar, and of tigers leaving a jungle in which a pack of wild dogs had taken up their quarters, have come to my own knowledge; and on one occasion a party of the officers of the 18th regiment M. N. I. saw a pack run into, and kill, a large Sambar stag near Dharwar. I once captured a bitch and seven cubs of this species, and had them alive for some time.—*Elliot, M. L. S. J. July* 1839.

(5131) *Canis lupus.*

Tola, Can. | Landgah, Duk.

This species does not appear to differ from the common wolf. Three young ones which I had alive for some time agreed very much with the description of the *Canis pallipes* of Colonel Sykes, but several adults that I shot differed in their colours and general character. The head was large, the muzzle thicker, the colours in some cases more inclining to rufous, particularly on the fore legs; which in some cases were deep red; and the same colour was found on the muzzle from the eyes to the nose. Others have more rufous on the hind legs, together with some black on the thighs, rump, and tip of the tail. Length from muzzle to insertion of tail 36 to 37 inches; do. of tail 16 to $7\frac{1}{2}$: height at shoulder 24 to 26; length of head 10; circumference of do. 16 to 17; weight of an adult female 42 lbs. The wolves of the Southern Mahratta Country generally hunt in packs, and I have seen them in full chase after the goat antelope (*Gazella arabica*). They likewise steal round the herd of *Antelope cervicapra*, and conceal themselves on different sides till an opportunity offers of seizing one of them unawares, as they approach, whilst grazing, to one or other of their hidden assailants. On one occasion, three wolves were seen to chace a herd of gazelle across a ravine, in which two others were lying in wait. They succeeded in seizing a female gazelle which was taken from them. They have frequently

been seen to course and run down hares and foxes; and it is a common belief of the ryots that in open plains, where there is no cover or concealment, they scrape a hole in the earth, in which one of the pack lies down and remains hid, while the others drive the herd of antelope over him. Their chief prey however is sheep, and the shepherds say that part of the pack attack and keep the dogs in play, while others carry off their prey; and that, if pursued, they follow the same plan, part turning and checking the dogs, while the rest drag away the carcass, till they evade pursuit. Instances are not uncommon of their attacking man. In 1824 upwards of 30 children were devoured by wolves in the Purgunnah of Rone. Sometimes a large wolf is seen to seek his prey singly. These are called *woo-tola*, and reckoned particularly fierce.

(5132) *Canis Aureus*, Lin.

Nari, CAN.; Kolah also Shighal, DUKHANI. The native sportsmen universally believe that an old jackal, which they call *bhalu*, is in constant attendance on the tiger, and whenever his cry is heard, which is peculiar and different from that of the jackal generally, the vicinity of a tiger is confidently pronounced. I have heard the cry attributed to the *bhalu* frequently.—*Elliot M. L. S J. July* 1839.

(5133) *Canis bengalensis*, Shaw and Pennant. —*C. Kokree*, Sykes.

Konk,
Kemp nari (red jackal) } CANARESE.
Chandak nari,
Lomri, Nomri. DUKHANI. Kokri, MAHRATTA.

Length from nose to insertion of tail 20 inches; do. of tail 14 in.; weight, male 7½ lb.; female 6¼ lb.—both large specimens. Shaw's animal appears to be identical with the *Canis Kokree* of Colonel Sykes. Its principal food is rats, land crabs, grasshoppers, beetles, &c. On one occasion a half devoured mango was found in the stomach. It always burrows in open plains, runs with great speed, doubling like a hare; but instead of stretching out at first like that animal, and trusting to its turns as a last resource, this fox turns more at first and if it cannot fatigue the dogs, it then goes straight away. It is remarkable that though the brush is generally tipt with black, a white one is occasionally found, while in other parts of India, as in Cutch, the tip is always white.—*Elliot M. L. S. J. July* 1839.

(5134) *Viverra Indica*, Geoff.—*Rasse*, Horsfield.

Punagin bekk, CAN. | Kasturi, MAH.
Mushk billi, DUK.

Length from the nose to insertion of tail 22 inches; do. of tail 15¾ in.—total 37¾—weight 5¼ lb.—an adult female. Varies much in the distribution of the marks on the fur. Specimens from the Southern Mahratta Country illustrative of this variety have been deposited in the British Museum.—*Elliot, M. L. S. J. July* 1839.

(5135) *Mangusta Mungus.—Herpestes Griseus*, Desm.

Mungli, CAN. | Mangoos, DUK.

There does not appear to be any difference between the *Mangusta Mungos* and *Mangusta Cafra*, both of which are referrible to the *Herpestes griseus* of Desmarest.—*Elliot. M. L. S. J. July* 1839.

(5136) *Mangusta Vitticollis.—Herpestes Vitticollis*, Bennett, Proceed. Zool. Sec. 1835, Part iii. p. 67. A specimen of this animal was procured in the thickest part of the ghat forests by accident, in 1829, and is now deposited in the British Museum. It is very rare, inhabits only the thickest wood, and its habits are little known. Size the same as *M. Grisea*. The animal was figured, first in 1839.—*Elliot. M. L. S. J. July* 1839.

(5137) *Paradoxurus Typus.*—Fr. Cuv.

Kera bek, CAN. | Menuri, DEK.

Common in the Mulnad, living in trees, thatched roofs of houses and huts, &c.

Huli, CAN. | Patayat Bag, DUK.
Bag, DUK. | Wahag. MAH.

The tiger is common over the whole district, breeding in the forest and mountain tracts, and coming into the open country when the grain is on the ground. In some places they do much mischief, and have been even known to carry off the inhabitants out of the villages, whilst sleeping in their verandahs during the night. The following are the largest dimensions of any tiger, male and female, killed in the Southern Mahratta Country, between the years 1829 and 1833

inclusive, and in affording a comparison of from 70 to 80 individuals.

	Adult Male. ft	in.	Do. ft.	in.	Adult Female. ft.	in.	Do. ft.	in.

—— of forearm above the elbow	2	3	,,	,,	,,	,,	,,	,,
Weight,	380 lbs.		360 lbs.		249 lbs.			

I have been thus particular in detailing the measurements of this species, because nothing is more common than to hear of tigers of 12, 14, and even 15 feet in length. Most persons content themselves with measuring the skins of an animal after it is taken off; and I once measured a lion of 9 feet 4 inches, which was noted by another of the party in his journal, as 11 feet: and by a third as 12—the one having measured the skin newly taken off and pulled out, the other when it was stretched to the uttermost by pegs, to dry. I do not believe that any tiger has ever been known that would exceed ten feet. The following particulars relative to the habits of the tiger were collected during several years. The female has from 2 to 4 young, and does not breed at any particular season. Their chief prey is cattle, but they also catch the wild hog, the *samber*, and, more rarely, the spotted deer. It is naturally a cowardly animal and always retreats from opposition until wounded or provoked. Several instances came to notice of its being compelled to relinquish its prey by the cattle in a body driving it off. In one case an official report was made of a herd of buffaloes rushing on a tiger that had seized the herd-boy and forcing it to drop him. Its retiring from the wild dog has already been adverted to. Though the wild hog often become its prey, it sometimes falls a victim to the successful resistance of the wild boar. I once found a full grown tiger newly killed, evidently by the rip of a boar's tusk; and two similar instances were related to me, by gentlemen who had witnessed them, one of a tiger the other of a panther. It is generally believed that a tiger always kills his own food and will not eat carrion. I met with one instance of a tigress and two full grown cubs devouring a bullock that had died of disease. I saw the carcass in the evening, and next day, on the report of tigers having been heard in the night, I followed their track, and found they had dragged the dead animal into the centre of a corn-field and picked the bones quite clean, after which they found a buffalo, killed it, and eat only a small portion of it. Another instance was related in a letter from a celebrated sportsman in Kandeish, who having killed a tigress, on his return to his tents, sent a pad elephant to bring it home. The messenger returned reporting that on his arrival he found her alive. They went out next morning to the spot and discovered that she had been dragged into a ravine by another tiger and half the carcass devoured. They found him close by and killed him also. The Bheels in Kandeish say, that in the monsoon, when food is scarce, the tiger feeds on frogs, and an instance occurred some years ago, in that province, of one being killed in a state of extreme emaciation, from a porcupine's quill that had passed through his gullett and prevented his swallowing, and which had probably been planted there, in his attempts to make one of these animals his prey. Many superstitious ideas prevail among the natives regarding the tiger. They imagine that an additional lobe is added to his liver every year; that his flesh possesses many medicinal qualities; that his claws arranged together so as to form a circle, and hung round a child's neck, preserves it from the effect of the evil eye. That the whiskers constitute a deadly poison, which for this reason are carefully burnt off, the instant the animals are killed. Several of the lower castes eat his flesh.

(5140) *Felis Pardus*, Lin.

The large variety—Honiga, CAN.
Tendwa, DUK.
Tendowa, of the Bauris or Chita catchers.
Asnea. Mahratta of the Ghats.

The smaller one—Kerkal. CAN.
Gorbacha DUK.
Bibla, of the Bauris.

Of this species there appear to be two varieties, a large and a small kind, though others are of opinion, that the smaller animal is the leopard. Col. Sykes also distinguishes two kinds of *cheta*, but considers the larger one to be the leopard. The natives distinctly recognize the two kinds by different names. Shaw says, the leopard is distinguished from the panther by its paler yellow colour, and again that the leopard is considerably the smaller of the two. Here the paler is the larger. The most remarkable difference between these seems to be that of size, but on a careful inspection, other particulars are detected. An examination of a large collection of skins, that had been brought for the Government reward, and were deposited in the office of the district, gave the following characters. The large skins measured from 4½ to 5 feet; the tail 2¾—7¾; the height appeared to be 2½; the smaller ones were 3 to 3½ ft. long; the tail 2½—6; the height was from 1½ to 2. The colour of the larger skins was generally pale fulvous yellow, the belly white, whilst others were deeper and more tawny, some being a sort of reddish yellow, without any white at all, beneath. In the *Kerkal* there is also a great variety of shade. But generally the

greater number of *Honigas* are pale coloured and of the *Kerkals* dark; whence probably the name of the latter from *kera*, dark or black. As a general rule too, the fur of the *Honiga* is shorter and closer: that of the *Kerkal* longer and looser. The character of the spots is always the same. They may be characterised as imperfect annuli, consisting of groups of spots, arranged in imperfect circles; but sometimes approximating more and becoming like trifoils ∴, squares : : or like the impression of a dog's foot, particularly along the dorsal line, and on the head, neck, shoulders, loins and legs. Where the ground colour is dark, the spots are more confused. The tail is without annuli, spotted throughout, but sometimes the spots run into each other at the end, giving the appearance of a black tip. The large variety is found chiefly among the rocky hills to the eastward, the smaller is more common in the wooded country of the Mulnad. The former is a taller, slighter, more active animal, exceedingly strong and fierce, the latter is smaller, and stouter, and varies much in size, some being not bigger than a large tiger-cat, though the skull proved them to be adult animals. The latter may be killed easily, while the *Honiga* is a very formidable assailant; and several instances occurred of as many as four men having been killed by one, before it was put *hors de combat*. The strongest marked difference of character that I observed, was in the skulls, that of the *Honiga* being longer and more pointed, with a ridge running along the occiput, and much developed, for the attachment of the muscles of the neck—while those of the *kerkal* were rounder and the bony ridge was wanting. If this character is universal and permanent, it will afford a good ground of distinction. At present I should be disposed to consider the Indian species as consisting of three varieties:

(*a.*) The larger or *Honiga*.

(*b.*) Ditto of a uniform black colour, the spots appearing when the light shines strongly on the skin, from the Malabar Coast.

(*c.*) The smaller variety or *kerkal*.

The following are the dimensions of a very large *honiga* killed in the *Mulnad*: length of body from nose to insertion of tail 4 ft. 6 in: tail 3-2; in all, 7-8; height at the shoulder 2 ft. 3½in. from ends of toes to top of shoulder 2—7; circumference of the arm below the elbow 1-3; head 7-11. This was a very large male called by the natives a *Marhoniga*, stouter than the generality of the larger kind.—*Elliot, M. L. S. J. July* 1839.

(5141) *Felis Jubata*, Lin.

Chircha, Chirtsa, CAN.	Yuz, Hindustani of the trainers.
Siwungi, do.	
Chita, DUK.	

They are caught in the district and trained to kill the *Antelope cervicapra*. They are taught always to single out the buck, which is generally the last in the herd; the *Meer Shikaries* are unwilling to slip until they get the herd to run across them, when they drive on the cart, and unhood the *cheeta*.—*Elliot, M. L. S. J. July* 1839.

(5142) *Felis chaus*, Gould.—*Felis affinis*, Gray.

Maut bek, CAN.	Waddar caste, who eat them.
Kadu bek or Kar bek,	
Bella bek, Do. of the	Jangli billi, DAK.
	Bhaoga, MAH. of Ghats.

From an examination of a number of skins deposited by me in the British Museum, Mr. Gray seems to consider the *Affinis* to be identical with *Chaus*.—*Elliot, M. L. S. J.*

(5143) *Felis. Wagatee.*

Wagati, MAH. of the Ghats.

This animal I was unable to identify with any of the species described so it may perhaps be a new one. It seems to differ both in size and colour from the *Felis Viverrinus* sent home by Mr. Heath, and described by Mr. Bennet. Proceed. Zool. Soc. 1833, Part I. p. 68. It is peculiar to the western ghat forests It approaches most nearly to the *Felis Tigrina* or *Margay*, Gm.; the *Felis Javanensis* or *Kuauk*, Horsf.; and the *Felis Diardi*. The *Wagati* (an adult male) is 26 inches long, from the muzzle to the insertion of the tail, which is nearly 11 more—in all nearly 37 inches. The colour is pale yellowish grey—darker on the back—yellowish white or pale yellow on the sides—white on the under parts of the body. The forehead has 4 longitudinal spots. In a line with these, from the vertex, four lines run to the shoulders, the outer broader, the centre ones narrower, and these two last are continued almost uninterruptedly to the tail; the others break diagonally into large longitudinal spots, which are continued in rows of smaller rounder spots to the centre of the belly. There are about six rows on each side, exclusive of the two dorsal lines. Two smaller bands run from the eye, and along the upper lip, to a throat-band running transversely below the ears. Two other similar transverse bands cross the breast with a row of spots between. The inside of the arm has two broad bands, and the soles are dark brown or nearly black. The tail is spotted on the upper half and indistinctly annulate towards the tip. It is very fierce—living in trees in the thick forests; and preying on birds and small quadrupeds. A *shikaree* declared that it drops on larger animals. and even on deer, and eats its way into the neck; that the animal in vain endeavours to roll or shake it off, and at last is destroyed.

(5144) *Mus.* The different Indian species of this family have hitherto been classed under three groups, *Mus*—*Arvicola*—*Gerbillus*. The species described are—

Mus Giganteus, ...Hardwicke.

—— Decumanus, ...Pallas.

—— Rattus, ...Lin.
—— Platythrix,.....Sykes.
—— Oleraceus, ...Sykes.
—— Musculus, ...Lin.
Arvicola Indica, ...Gray and Hardwicke.
Gerbillus Indicus, ...Hardwicke.

None of these, however, except the species common to Europe, seem to have received more than a general description of their outward form, and accordingly, on looking closer into the details of their structure, and particularly to the character of their teeth, a different disposition seems necessary. Of *Arvicola* there is no example; the species characterised by Gray having molars with flat coronals, and strong radicles, in this respect assimilating with the sub-genus *Neotoma*, established by Messrs. Say and Ord in the Philadelphia Journal.

The *Mus Giganteus* of Hardwicke exhibits similar characters, but they both differ from the Florida rat, the type of *Neotoma* (as figured), in having the naked scaly tail of the common rat, whereas in the Florida species it is covered with hair.

The *Gerbillus Indicus* of Hardwicke unites both these characters, the surface of the molars being the same as that of the two Indian species indicated above, while the tail has the same peculiarity as the Florida rat, with the addition of a tuft at the extremity. But it is separated from the latter by the length of the hind foot, and the disposition of the toes, and by the carinated upper incisors; characters peculiar to *Gerbillus*. These common points of resemblance, however, show how intimately the different groups are connected and how gradually they pass into each other. The remaining species all belong to the group of *Mus* proper, with tuberculated cheek teeth.

Of the other species, not included, that have been indicated by authors, no examples have been observed. These are *Mus Indicus* of Geoffrey, Cat. Mus. Par. Desm. VI. 299, which may perhaps be identified with Gray's *Arvicola*. The *Mus striatus* of Seba, [These II. 22.] adopted by Linnæus, Shaw, [Zool. VI. t. 133.] and the French Naturalists, [Ency. Meth. t. 68, f. 6.] has never been observed; neither has the spiny rat of Pondicherry (M. Perchal).

The species observed in the Southern Mahratta Country were—with flat molars:

a. scaly tails—short metatarsi (*Neotoma*).
Mus giganteus.
Arvicola indica.

b with hairy tail—long metatarsi (*Gerbillus*).
Gerbillus Indicus.

With tuberculated molars:

a. Covered with soft hair (*Mus*).

Mus Decumanus..... Lin.
„ Rattus..... Lin.
„ Mettade..... New sp.
„ Golundee..... New sp.
„ Oleraceus..... Sykes.
Mus Rufus..... New sp.
„ Musculus..... Lin.

b. Covered with hair and spines.

Mus Platythrix..... Sykes.
„ Boodaga..... New sp.

The first division have 3 molars in each jaw, with strong alveolar processes; the anterior or largest one divided into three sections by transverse ridges of enamel; the middle into two, and the third partly, or entirely so, as the centre ridge of enamel extends altogether, or only partly across the surface. In *Giganteus* and *Gerbillus* the enamel of the posterior molar of the upper jaw generally forms only a deep indentation. In *Gerbillus* the incisors are more prismatic, the upper ones divided by a longitudinal furrows passing down the centre. In the other two species the incisors are smooth, rounded, with a longitudinal mark on the worn under surface. The upper incisors in *Gerbillus* also are much more curved downwards than in the other two. In the former the usual and superior maxillary bones project considerably beyond the incisors; in the latter the incisors extend beyond these bones.

(5145) *Mus* (*Neotoma*) *giganteus*, Hard. Lin. Trans.—*Mus. Malabaricus*, Pennant, Quad.

Heggin, Can. | Ghons, Duk.
Pandi koku, Tel. |

The English name, bandicoot, is a corruption of *pandi-koku*, literally pig-rat. Lives in granaries and stack-yards; feeds entirely on grain. Fierce, bold, easily killed. Makes a peculiar grunting noise when frightened or angry. Female with 12 teats. Incisors dark olive green at the base; becoming yellow at the extremities.

(5146) *Mus* (*Neotoma*) *providens*.—*Mus Indicus*, Geoff.—*Arvicola Indica*, Gray.

Kok, Canarese.

It seems necessary to distinguish this species by a new name, that of *Indicus* being too general and indefinite. Geoffroy's animal is not sufficiently particularized to indicate which of the Indian species he meant; and Gray's was given under the supposition that it applied to an *Arvicala*, which he subsequently discovered it did not: Journal Zool. Soc. July 28, 1835, p. 108. The present term seems sufficiently applicable to its habit of laying up a large store of grain for its winter food. The *kok* is from 13 to 14 inches in length, and weighs upwards of 6 oz. Its figure is thick and strong, with powerful limbs, the head short and truncated, the ears small, subovate or nearly round, and covered with a fine down or small-hairs. The tail naked and nearly as long as the body, whiskers long and full. Fur long and somewhat harsh, brown mixed with fawn, the short fur softer and dusky. The colour generally being something like that of the brown rat, with more fawn or red intermixed, and

lighter beneath. In its habits it is solitary, fierce, living secluded in spacious burrows, in which it stores up large quantities of grain during the harvest, and when that is consumed lives upon the *kuryalee* grass and other roots. The female produces from 8 to 10 at a birth, which she sends out of her burrow as soon as able to provide for themselves. When irritated, it utters a low grunting cry, like the bandicoot. Incisors entirely of an orange yellow colour. The dimensions of an old male were as follows :— length of body 7 inches; of tail $6\frac{1}{2}$; total $13\frac{1}{2}$: of head $1\frac{8}{10}$; of ear $\frac{9}{10}$ths; of fore palm $\frac{4}{10}$ths; of hind $2\frac{4}{10}$ths. Weight 6 oz. 5 drs. The race of people known by the name of *Wuddurs*, or tank-diggers, capture this animal in great numbers as an article of food; and during the harvest, they plunder their earths of the grains stored up for their winter consumption, which, in favourable localities, they find in such quantities, as to subsist almost entirely upon it, during that season of the year. A single burrow will sometimes yield as much as half a seer (about a lb) of grain, containing even whole ears of *jowaree* (*Holcus sorghum*). The *kok* abound in the richly cultivated black plains or cotton ground but the heavy rains often inundate their earths, destroy their stores and force them to seek a new habitation. I dug up a winter burrow in August 1833, situated near the old one, which was deserted from this cause. The animal had left the level ground, and constructed its new habitation in the sloping bank of an old well. The entrance was covered with a mound of earth like a mole-hill, on removing which the main shaft of the burrow was followed along the side of the grassy bank, at a depth of about 1 or $1\frac{1}{2}$ foot. From this, a descending branch went still deeper to a small round chamber; lined with roots and just large enough to contain the animal. From the chamber a small gallery ran quite round it, terminating on either side in the main shaft at the entrance of the chamber; and the passage then continued down to the bottom of the bank, and opened into the plain. Near the upper entrance, and above the passage to the chamber, was another small branch, which terminated suddenly and contained excrement. But these burrows are by no means on a uniform plan. Another occupied by an adult female was likewise examined in the same neighbourhood. It was much more extensive, and covered a space of about 15 feet in length, about 8 in breadth, also in a grassy mound, of which it occupied both sides. Six entrances were observed, and there may have been more, each covered with loose earth. The deepest part of the burrow near the chamber was about three feet from the surface; the chamber raised a little above the shaft, which terminated abruptly and was continued from the upper part of the chamber. The chamber lined with roots of grass and bark of the date-tree. The branching galleries, of which there were six, from the principal shaft, appeared to have been excavated in search of food. A variety found in the red soil is much redder in colour than the common *Koku* of the black land. Another variety is said to frequent the banks of nullahs and to take the water when pursued, but the specimens I have seen differed in no respect from the common kind (of which they appeared to be young individuals), except in size.

(5147) *Mus* (*Gerbillus*) *Indicus*, Hardw.

Billa Ilei, CAN.
Yeri yelka, Tel yellka } of Wuddurs.

This species has already been fully described, and some peculiarities in its cranium have been noticed above. The muzzle appears to be more pointed than stated by General Hardwicke, who characterizes it as "very round," and the colour is always of uniform bright fawn, without any admixture of brown spots, which have never been observed. The incisors are always of a deep yellow colour; the eyes very large and full, the tail longer than the body. A large adult male measured—length of body 7 inches; of tail $8\frac{1}{10}$; of head $2\frac{1}{10}$; of ear $\frac{2}{10}$; of fore foot $\frac{5}{10}$; of hind foot 2. Wight $6\frac{5}{4}$ oz. They are said to be very prolific, bringing forth 16 to 20 at a birth, but this seems an exaggeration, and the litter probably seldom exceeds 12. It is the common prey of foxes, owls, snakes. Lives in numerous societies, making extensive burrows in the red gravelly soil of the Mulnaad, generally in or near the root of shrubs or bushes. The entrances, which are numerous, are small, from which the passage descends with a rapid slope for 2 or 3 feet, then runs along horizontally, and sends off branches in different directions. These galleries generally terminate in chambers from $\frac{1}{2}$ a foot to a foot in width, containing a bed of dried grass. Sometimes one chamber communicates with another, furnished in like manner, whilst others appear to be deserted and the entrances closed with clay. The centre chamber in one burrow was very large, which the *Wuddurs* attributed to its being the common apartment, and said that the females occupied the smaller ones with their young. They do not hoard their food, but issue from their burrows in the evening, and run and hop about, sitting on their hind legs to look round, making astonishing leaps; and, on the slightest alarm, flying into their holes. The Wuddurs eat this species also. —*Elliot, M. L. S. J. Oct.* 1839.

(5148) *Mus Decumanus*, Lin.

Manei ilei, CANARESE.
Chooha, and Ghur ka chooha. } DEKHANI.

Not so common above the Ghats as below.—*Elliot M. L. S. J. Oct.* 1839.

(5149) *Mus Rattus*, Lin. Rare.—*Elliot M. L. S. J. Octr.* 1839.

(5150) *Mus lanuginosus.*—New species.

Mettade, of the Wuddurs. | Kera ilei, CAN.

The name adopted to designate the species is taken from the word *mettade*, meaning soft, in allusion to its fur, which is fine and soft—*mettani* meaning soft in Telugu. It is also called *mettau-yelka, mettan-ganda*, from the same cause. It is about half the size of the *kok*, which it somewhat resembles. The head is short, but the muzzle, instead of being square and truncated, is sharp; the ears are larger in proportion and more ovate. The general form is not so stout. The tail is shorter than the body. The colour above is reddish brown, with a mixture of fawn; lighter beneath, close and soft, with a few longer hairs projecting. A large adult male measured:—length of body, $5\frac{6}{10}$th inches; of tail, $4\frac{3}{10}$ths; total $9\frac{9}{10}$ths; of head $1\frac{4}{10}$th; of ear $0\frac{8}{10}$th. Weight $2\frac{1}{2}$ oz. The *mettade* lives entirely in cultivated fields, in pairs, or small societies of five or six, making a very slight and rude hole in the root of a bush, or merely harbouring among the heaps of stones thrown together in the fields, in the deserted burrow of the *kok*, or contenting itself with the deep cracks and fissures formed in the black soil during the hot months. Great numbers perish annually, when these collapse and fill up at the commencement of the rains, The monsoon of 1826 having been deficient in the usual fall of rain, at the commencement of the season, the *mettades* bred in such numbers as to become a perfect plague. They ate up the seed as soon as sown, and continued their ravages when the grain approached to maturity, climbing up the stalks of *jowaree*, and cutting of the ear to devour the grain with greater facility. I saw many whole fields completely devastated, so much so, as to prevent the farmers from paying their rents. The ryots employed the *Wuddurs* to destroy them, who killed them by thousands, receiving a measure of grain for so many dozens, without perceptibly diminishing their numbers. Their flesh is eaten by the Tank-diggers. The female produces from 6 to 8 at a birth.—*Elliot, M. L. S. J. October* 1839.

(5151) *Mus hirsutus.*—New species.

Gulandi or Gulat yelka, CAN. of the Wuddurs.

The *Gulandi* is about the size of the last species, or a little larger—but differs from it in living entirely above ground, in a habitation constructed of grass and leaves, generally in the root of a bush at no great height from the ground, often indeed touching the surface. The head is longer than that of the *Mettade*, but the muzzle is blunt, rounded, and more obtuse, and covered with rough hair. The face and cheeks are also rougher than those of the other rats; the ears round and villose; the eyes moderate; the whiskers long and very fine. The tail naked and scaly, somewhat villose. The colour is an olive-brown above, mixed with fulvous; beneath yellowish tawny; sometimes paler, or light yellowish grey. A male *Gulandi* measured:—length of body, $6\frac{2}{10}$th; of tail, $4\frac{3}{10}$th; total $10\frac{5}{10}$th: of head, $1\frac{1}{10}$th; of ear, $0\frac{6}{10}$th. Weight nearly 3 oz. The *Gulandi* lives entirely in the jungle, choosing its habitation in a thick bush, among the thorny branches of which, or on the ground, it constructs a nest of elastic stalks and fibres of dry grass, thickly interwoven. The nest is of a round or oblong shape, from 6 to 9 inches in diameter, within which is a chamber about 3 or 4 inches in diameter, in which it rolls itself up. Around and through the bush are sometimes observed small beaten pathways, along which the little animal seems habitually to pass. Its motion is somewhat slow, and it does not appear to have the same power of leaping or springing, by which the rats in general avoid danger. Its food seems to be vegetable, the only contents of the stomach that were observed being the roots of the *huryalee* grass. Its habits are solitary (except when the female is bringing up her young), and diurnal, feeding during the mornings and evenings.—*Elliot, M. S. L. J. Oct.* 1839.

(5152) *Mus olerareus*, Sykes.

Meinalka, or Meina yelka, CAN. of the Wuddurs.
Marad ilei, CAN.

This species has, by mistake, been designated as *M. Longicaudatus* in the distribution list at page 94, a term applied to it in Mr. Elliot's notes, some years ago, when he believed it to be undescribed, as in fact it was at the time, but it was subsequently noticed by Mr. Bennet from a specimen taken home by Colonel Sykes. [Proceedings, Zool. Soc. July 26, 1832.—P. 121.] Its colour is a bright chesnut above, beneath pure white. Head moderate, muzzle somewhat obtuse, ears ovate, tail naked. The dimensions of a young female were:—length of body, 3 inches; of tail, $4\frac{3}{10}$ths; total $7\frac{2}{10}$ths; of head, 1; of ear, $0\frac{5}{10}$ths. The *Meinalka* is extremely active and agile, and difficult to catch. I never procured its nest, but was told by the Wuddurs it lived always in bushes or trees, up which it is able to run with great facility. Colonel Sykes merely observes that "it constructs its nest of leaves of oleraceous herbs, in the fields." Whence the designation he has adopted for it.—*Elliot, M. S. L. J. Oct.* 1839.

(5153) *Mus flavescens*,—New species. This species somewhat resembles the last, but is nearly double the size, is of a paler yellow colour, and was met with only in out-houses and stables at Dharwar, but there in considerable numbers. Habits social. It has been designated as *Mus rufus* in the list at page 94; but besides that, this term has been appropriated to other species, it does not express the particular colour so well as that now adopted. This is a pale yellowish

brown above, and white beneath. The head is long, the muzzle pointed, the ears very large, sub ovate. Dimensions of an adult male :— length of body 5½ inches ; of tail 6½ ; total 12. Weight 12½ oz.—*Elliot, M. L. S. J. Oct.* 1839.

(5154) *Mus musculus*, Lin.

Manei Buduga, CAN.

This I always considered to be the common mouse, but Mr. Gray considered a specimen given to the British Museum to differ from the European species.—*Elliot, M. L. S. J. Oct.* 1839.

Spiny Rats.

(5155) *Mus platythrix*, Sykes.

Leggyade, Kal yelka, of Wuddurs	Kul ilei, CAN.

The *leggyade* has also been described by Mr. Bennet from Colonel Sykes' specimen. [Proceedings, Zool. Soc. June 26, 1832.—P. 121.] I had proposed to call it *M. Saxicola* as better expressive of its habits, and as being exactly equivalent to its native name ; *platythrix* expressing a generic rather than a specific character. It has the head oblong, the muzzle pointed, the ears rather large, oblong, rounded. Incisors yellow. Colour light brown, mixed with fawn ; beneath pure white ; the white separated from the brown by well defined pale fawn line. The flattened spines are transparent on the back, beneath smaller, and forming with a fur a thick close covering. The dimensions of an

——— of hind palm	,,	,, 7/10	
Weight	1 oz.	15 drs.	

The *leggade* lives entirely in the red gravelly soil, in a burrow of moderate depth, generally in the side of a bank. When the animal is inside the entrance is closed with small pebbles, a quantity of which are collected outside ; by which its retreat may always be known. The burrow leads to a chamber, in which is also collected a bed of small pebbles, on which it sits, the thick close hair of the belly protecting it from the cold and roughness of such a seat. Its food appears to be vegetable. In its habits it is monogamous and nocturnal. In one earth which I opened, and which did not seem to have been originally constructed by the animal, but to have been excavated by ants, I found two pairs ; one of which were adults, the other young ones about three parts grown. The mouth of the earth was very large, and completely blocked up with small stones ; the passage gradually widened into a large cavity, from the roof of which some other passages appeared to proceed, but there was only one communication with the surface, viz. the entrance. The old pair were seated on a bed of pebbles, near which, on a higher level, was another collection of stones, probably intended for a drier retreat. The young ones were in one of the passages likewise furnished with a heap of small stones.—*Elliot, M. L. S. J. Oct.* 1839.

(5156) *Mus lepidus.*—New species.

Buduga, CAN. ; Chitta, burkani, Chit yelka, Chitta ganda, TEL. of Wuddurs.

This pretty little species resembles the preceding, but is only about one third of the size. The colour is similar, but paler, and it has the same pure white under surface, separated from the upper by an exact line. The spines are small, fine, transparent, and of a dusky tinge, tipt with fawn. The head is very long, being nearly one third the length of the body, and the muzzle pointed. The ears are large, ovate, naked. Incisors white. Tail naked, scaly. Limbs rather long, fine ; the 3 middle digits of the hind foot produced, as in *Gerbillus*, the two outer ones much shorter and nearly equal. The dimensions of an old male were—length of body 2 9/10th inch ; of tail, 2 7/10th ; total 5 6/10th ; of head 9/10th ; of ear 4½-10th ; of fore palm 2½-10th ; of hind palm 6/10th ; weight 6 drs., but in general it does not exceed a ¼ of an oz. (or 4 drs.) Lives generally in pairs in the red soil, but sometimes a pair of young ones is found in the same burrow with the old ones. Does not produce more than 4 or 5 at a birth. —*Elliot, M. L. S. J. Oct.* 1839.

(5157) *Sciurus Palmarum*, Gmel.—*Rat Palmiste*, Brisson.

a. common variety.

b. darker coloured, peculiar to the Ghats.

Alalu, CAN. Gilheri. DUK.	Urta, of the Wuddurs.

The common species is sufficiently well known ; the other, found only in the forests of the Ghats, is darker, the front and the back between the stripes reddish brown, the stripes small, narrower than in the common kind, and not extending the whole length of the back. The size of both is the same.—Length, 13 to 14 inches ; weight of males, 4 oz. 12 drs. ; females 4 oz. 11 drs. The young are born without any hair, but three dark lines are visible along the back indicating the position of the future stripes.—*Elliot, M. L. S. J. Oct.* 1839.

(5158) *Sciurus maximus*, Gmel.—*S. Elphinstonii*. Sykes.

Shekra, MAH. of the Ghats.	Kes Annalu, CAN. of the Halapyks.

I have observed the same uniformity of colour in the Ghat variety that has been described by Colonel Sykes ; but it seems doubtful whether mere difference in colour, constitutes sufficient

grounds for the formation of a new species. I have had both the black and the red kinds alive, and tame, in my possession, for months together, and I observed the most perfect similarity in their habits, cry, and in every particular except in that of colour. Though I never met with individuals of the *S. Maximus* in the forest, I have often obtained them from the people of the country, who said they caught them in the Southern parts of the mountain range. The same disposition to vary in the shade and distribution of colour has been remarked by Dr. Horsfield in the Java congener of the Indian species, the *Jeralang*, or Leschenault's squirrel, a specimen of which has been described by Geoffroy as *S. Albiceps* from a casual difference of this kind. These varieties probably depend on locality, and have given rise to a great multiplication of species. Thus we have the *S. Macrurus* : of Gmel., identified by Cuvier with *S. Maximus S. Ceylonensis* of Ray ; *S. Indicus* said to come from Bombay, &c. Fischer makes the distinction between *S. Maximus*, and *Macrurus* to consist in the former having the cheek stripe terminating simply, while in the latter it is forked. J. B. Fisch. Syn. p. 363.—*Elliot, M. L. S. J. Oct.* 1839.

(5159) *Pteromys Philippensis ?*—New species.

Pukhya or Pakya, MAH. of the Ghats.

Mr. Gray designated the specimens of this species presented to the British Museum by the specific name of *Philippensis*, and showed a former description of them under this title, the source of which I have mislaid. I cannot however find any such species indicated in Griffith's Synopsis, in Fischer's Mammalia, nor in any works to which I have access. The length of the male is 20 inches, and the tail 21=41 inches : that of the female 19, and the tail 20=39 inches. The colour above is a beautiful grey, caused by the intermixture of black with white and dusky hairs ; beneath it is white, the legs and posterior half of the tail black. The male is distinguished by an irregular patch of rufous on the sides of the neck, which in the female is a sort of pale fawn. It is very gentle, timid, and may be tamed ; but from its delicacy is difficult to preserve. Lives in the holes of trees in the thickest part of the forest.—*Elliot, M. L. S. J. Oct.* 1839.

T'hiriya do.		Alawa,	
		Shallama,	of the Bauris.
		Shalma,	

The Manis burrows in the ground, in a slanting direction, to a depth of from 8 to 12 feet from the surface, at the end of which is a large chamber, about 6 feet in circumference, in which they live in pairs, and where they may be found with one or two young ones about the months of January, February, and March. They close up the entrance of the burrow with earth, when in it, so that it would be difficult to find them ; but for the peculiar track they leave. A female that I kept alive for some time, slept during the day, but was restless all night. It would not eat the termites or white ants put into its box, nor even the large black ant (*Myrmex indefessa*, Sykes) though its excrement at first was full of them. But it would lap the water that was offered to it, and also conjee or rice water, by rapidly darting out its long extensive tongue, which it repeated so quickly as to fill the water with froth. When it first came it made a sort of hissing noise, if disturbed, and rolled itself up, the head between the four legs, and the tail round the whole. The claws of the forefeet are very strong, and in walking are bent under, so that the upper surface is brought in contact with the ground ; its gait is slow, and the back is curved upwards. After its death a single young one was found in it (Sept. 15th), perfectly formed, and about 2 inches long. The marks of the future striated scales were distinctly visible, and its long tongue was hanging out. The tongue of the old one was 12 inches in length, narrow, flat fleshy to the tip, the muscle along the lower surface very strong. The length of the animal was 40 inches. The weight 21-lbs. *Elliot. M. L. S. J. Oct.* 1839.

(5163) *Elephas Indicus*, Cuv. *Mem. de l'Inst.*

Anei, CAN. | Hathi, DUK.

The elephant is rare above the ghats, but occasionally a stray male makes his way up, and does much mischief to the rice-fields and gardens. —*Elliot, M. L. S. J. Oct.* 1839.

Handi,		Boorra Janwar,	
Mikka,	CAN.	Sur,	DUK.
Jevadi,		Dukur,	MAH.

The Indian wild hog differs considerably from the German. The head of the former is longer and more pointed, and the plane of the forehead straight, while it is concave in the European. The ears of the former are small and pointed, in the latter larger and not so erect. The Indian is altogether a more active looking animal ; the German has a stronger heavier appearance. The same differences are perceptible in the domesticated individuals of the two countries.—*Elliot, M. L. S. J. Oct.* 1839.

Common in the forest and even occasionally seen in the Mulnad.—*Elliot, M. L. S. J. Oct.* 1839.

(5166) *Cervus* (*Rusa*) *Hippelaphus*, Cuv.

Kadavi, CAN. Samber, MAH. and DUK.	Bara Singh Erroneously of Mahomedans, Meru, MAH. of the ghats.

There is only one species of *Rusa* found in the Western forests, which is common also to all the heavy jungles of Southern India. None of the descriptions given by Hamilton Smith to the different Indian species, under the names of *Hippelaphus*, *Aristotelis*, *Equinus*, apply exactly to it: but I have little doubt that all three are only varieties of the great Indian stag, originally described by Aristotle under the designation of *Hippelaphus*, and discriminated as such by Mr. Duvancel, in the Asiatic Researches, vol. xv. p. 174; to which it is not improbable the *C. Unicolor or Gona* of Ceylon, is also referrible. The points of distinction that have been noticed are, the characters of the horns, size, colour, absence or presence of a disk on the buttocks, canine teeth, and minute distinctions in the proportions of the bones of the skull. The horns of different individuals present great diversities of form. The only common characters are those of a basal antler, springing directly and equally with the beam from the bur; and the beam terminating in a bifurcated extremity, formed by a branch or snag separating posteriorly and pointing obliquely to the rear. But I have met with instances of medial antlers, of trifurcated extremities, and in one case, with the extremity showing a fourfold division, as in a *Samber* killed by Captain Green, Madras Engineers, in the Bellarungin Hills between Mysore and Coimbatore. Plate 4 fig. 1. The size of the Southern *Rusa* is large, sometimes exceeding 14 hands in height. The colour varies from dark greyish black or slate-black; with the chin, the inner sides of the limbs, the under part of the tail, and the space between the buttocks, yellowish white, passing into orange yellow, but never extending into a large circular disk on the buttocks. In several instances I have met with the hinds of a pale yellow or light chesnut colour. These were young individuals, but the *shikaries* always declared them to be the same as the common kind, and no other difference was perceptible. The cranium of one of these light coloured females presents no structural differences from that of a young black female. Both sexes have canine teeth in the upper jaw, springing from the suture between the maxillary and intermaxillary bones. The neck and throat are clothed with a long mane. The suborbital sinus is very large. When the animal is excited, or angry, or frightened, it is opened very large, and can be distended at pleasure. The new horns are soft and tender during the mousoon, from June to September, about which time the rutting season commences. The stags are then fierce and bold. I have seen one, when suddenly disturbed, face the intruder for a moment, shaking his head, bristling his mane, distending the suborbital sinus and then dashing into the cover.—*Elliot, M. L. S. J. Oct.* 1839.

(5167) *Cervus Axis*, Erxleben.

Sarung Saraga, CAN.	Chital. MAH. and DUK.

(8168) *Cervus Muntjak*, Zimmermann.

Kankuri, CAN. Bekra, MAH.	Jungli Bukra, DUK.

This animal does not seem to differ in any respect from the *Kijang* of the Eastern Islands. A young male of this species was in my possession for many months, and was quite tame. It was of a deep chesnut colour, which becomes browner as the animal grows older. On the face appeared the plaits or ribs of skin between the eyes, running up to the fore-head and ending in a triangular patch of stiff hairs of a dark brown colour, at the upper side of which the horn afterwards sprouted, making its first appearance in the month of August. It had white spots in front of the fetlocks of all the four legs, and a little white likewise on the chin, upper throat, inside of arm-pits and thighs, and under the tail, but none on the lower part of the throat or on the belly. It used to lick its face with its tongue, which was remarkably long and extensible, reaching back over the eyes and the whole face, and frequently uttered a short, small cry, sharper than that of a kid. It obtains its Canarese name from its habit of frequenting the *Kans*, or natural forest gardens.—*Elliot M. L. S. J. Oct.* 1839.

(5169) *Antilope cervicapra*, Pallas.

Alali of the Baoris. The *Baorees* or *hurn shikarees*, called also *Aravi-Chinchers*, are a singular nomade tribe who live entirely by capturing antelope by means of springes, in which they are very successful. They also catch the Chita (*Felis Jubata*) for the *Meer Shikaries*. They wear a dress of a sort of brown coloured cloth peculiar to themselves and speak a dialect of Hindu with a very singular intonation.		the Buck.
Gundoli, of the Baoris, ...		the Doe.

Frequents the black plains, in herds of sometimes 20 or 30, each of which has only one buck of mature age, the others being young ones. The buck of the herd always drives off the others, as soon as they begin to turn black, in the course of which desperate combats ensue, by which their horns are often broken. The horns of the male in the Southern Mahratta Country seldom exceed 19 or 20 inches. The longest I have seen of a great number of specimens is 22 inches, with 4 flexures in the spiral twist; but I have seen a pair of horns from Hydrabad, 24 inches long, with 5 flexures and 50 rings or annuli; and another pair from Kattewar which were 25 inches. The rutting season commences about February, or March; but fawns are seen of all ages, at every season. During the spring months the buck often separates a particular doe from the herd and will not suffer her to join it again, cutting her off and intercepting every attempt to mingle with the rest. The two are often found alone also but on being followed always rejoin the herd. When a herd is met with, the does bound away for a short distance and then turn round to take a look—the buck follows more leisurely, and generally, brings up the rear. Before they are much frightened they always bound or spring, and a large herd going off in this way is one of the finest sights imaginable. But when at speed the gallop is like that of any other animal. Large herds are found about Hookerry, and thence towards the Kistna, keeping to the high rocky basaltic eminences, called by the Natives *mal*. It is remarkable that the gazelle is rare on these situations so well adapted to their habits. Some of the herds are so large, that one buck has from 50 to 60 does, and the young bucks driven from these large flocks are found wandering in separate herds, sometimes containing as many as 30 individuals of different ages. They show some ingenuity in avoiding danger. In pursuing a buck once into a field of toor, I suddenly lost sight of him and found after a long search that he had dropt down among the grain and lay concealed with his head close to the ground. Coming, on another occasion, upon a buck and doe with a young fawn, the whole party took to flight, but the fawn being very young, the old ones endeavoured to make it lie down. Finding however, that it persisted in running after them, the buck turned round and repeatedly knocked it over in a cotton field until it lay still, when they ran off endeavouring to attract my attention. Young fawns are frequently found concealed and left quite by themselves.

(5170) *Antilope arabica*, Hemprich and Ehrenberg. Fischer's Synopsis *b*.5. p. 460.—*A. Bennettii*, Sykes.

Budari, CAN. of southern talooks.	Chikara, DEK.
Tiska, CAN.	Porsya, of Baoris, the Buck.
Mudari. CAN. of northern talooks.	Chari, ditto. Doe.

The Indian gazelle always appeard to me to be new and undescribed, until I met with the Arabian species on the Southern and Eastern shores of Arabia in 1833; a careful examination of several individuals, both in a state of captivity, and that had been shot, convinced me that they were identical with the Indian species. And in this, I was confirmed by the opinion of M. Ruppell, formed on inspection of a stuffed skin taken home by me. They abound also in the islands of the Red Sea, particularly in Dhalak, and on the western shore about Massowa, and probably all along the Abyssinian Coast. The gazelle of the Hauran and of Syria, appeared also to be of this species; but I never had an opportunity of examining one closely. If this be the case, the *Chikara* possesses an additional interest, in being the same animal as the roe and the roe buck of Scripture. The modern name for the gazelle in Yemen is ضبي Dabi or Dzabi which is the same as the Hebrew word translated "Roe." Deut. 14, 5. It is likewise the gazelle of the Arabian poets, as appears from the common saying احور من كل الضبي "The eyes of the Dabi are the most beautiful of all." It is found on the red sandy plains, or among stony open hills, and abounds in the basaltic formation of the Dekhun, in the valleys of the sandstone formation, and generally among the jungles of the red soil to the eastward of the Southern Mahratta Country. It is never seen on the black plains, nor among the western jungles, nor in the Mulnad. It is found frequently in herds of three, generally a buck with two does; also of 5, 6, or more. The young expelled bucks are also found in separate herds like those of *A. cervicapra*. When two bucks fight they butt like rams, retiring a little and striking the foreheads together with great violence. When alarmed it utters a sort of hiss by blowing through the nose and stamps with the fore-foot, whence its Canarese name of *Tiska*. The dimensions of an adult male procured at Dumbal in the Southern Mahratta Country, the skin of which is now in the British Museum, were as follows: height at the shoulder 2 feet, 2 inches; at the croup 2 feet 4½ inches; length from the nose to insertion of the tail 3 feet, 5½ inches; of tail 8½ inches; of ear 6 inches; of horns 11 in.; of head 9 in. Weight 48-lbs. But these are by no means the largest dimensions observed. At Deesa in Goozerat, where it is much more common, I measured three crania, the dimensions of the horns of which were—

Length,	10½ in.	10¾ in.	11½ inches.
Distance between the points,	6½	6½	5
Number of annuli.	14	16	18

including the two imperfect ones near the tip. The third or largest were very little lyrated; the 2d were the strongest and thickest. I have also killed the buck weighing 51-lbs., the does weighed from 35 to 40-lbs. This is about half the weight of *Cervicapra* which varies from 90 to 100-lbs. The adult female has the horns inclining more to the rear, curved backwards, the tips forwards, slightly wrinkled at the base, the rest smooth and black, and nearly equi-distant. In both, the lachrymatory sinus is small and black. There is a dark spot on the nose, and a line from the eyes to the mouth surmounted by a light one. Knee-brushes, tail and fetlocks behind, black; chin, breast, and buttocks behind, white. Rest of the body, dark fawn deeper where it borders the white on the sides and buttocks. Ears long, 3 ridges of hair along the inner surface. Inguinal pores, 2 mammæ. Horns of the female sometimes with a few imperfect annuli, and never corresponding with each other.

(5171) *Antelope Sub-4-Cornutus* ?—New species ?—*Antelope Chikara* Hardwicke.—*Brown Antelope*, Sykes.

Kondguri, Can. | Junglibukra, Dek.

It is not improbable that the *chikara* (a name, by the way most incorrectly applied to this species, being restricted by all natives to the preceding one), the *Quadricornis* of Blainville, and the *Striaticornis* of Leach—all refer to the same animal. But the descriptions being only from isolated individuals, have not been sufficiently discriminated to determine the point. The detailed description of General Hardwicke in the Linnæan Transactions, differs in many important particulars from the characters of the Dekhan species. This is much larger, and the colour varies considerably both from the Hindostan *chikara*, in which it is of a "uniform bright bay," and in the shades of individuals of different ages in the Dekhan. The spurious horns are so small, as rarely to be met with in adult individuals, and are situated on two osseous bumps or risings (strongly marked in the cranium) from which they seem to be easily detached. These osseous risings are immediately in front of the true horns, between the orbits, rather in front of a line drawn across the forehead through the centre of the eyes, and become covered with black callous skin, after the loss of the corneous tips. The true horns are situated behind the eyes or between the eyes, and the ears, inclining backwards with a scarcely perceptible curve forwards, straight, parallel, round, smooth, thick, and strong at the base which has a few wrinkles, and tapering to a point, their colour black. Those of a very old male were 4¾ inches in length and had 3 strong wrinkles, and one imperfect one at the base. The dimensions of a young adult male were: Height at the shoulder, 2 feet 1½ inch; croup 2 feet, 3 inches; length from the muzzle to the insertion of the tail, 3 feet, 6 inches; of tail 5 inches; ear 4¼; horn 4; from the muzzle to the base of the horn, 6; of head 8; leg 1 foot, 5 inches. Weight 43-lbs. But I have found them even heavier. The doe is about the same size and has no horns, nor any bony projection above the eyes. The mammæ are four in number. The colour is brown, of various shades, not bright, but sometimes so light as to approach a dull fawn, darker than the *Cervicapra*, but not so bright and deep as in the gazelle. The shade is browner on the hind quarters, and darkest on the middle of the back. It becomes lighter on the sides till it passes gradually into white in the middle of the belly, without the well defined dark line of separation, observable in the other two species. The forelegs, particulary above the knee, the inside of the fetlocks, the nose and edge of the ears, are very dark. A narrow line between the fore-legs which gradually widens towards the hinder flanks, the inside of the arms and thighs, are white as is the inside of the ear, in which the hairs are long, and arranged in indistinct ridges. The lachrymatory sinus is long, narrow and parallel with the line of the nose. In its habits, it is monogamous, and is always found in pairs, frequenting the jungles among the undulating hills of the Mulnad. It is never found in the open country, or among the hills on the eastern side of the district, neither does it ever penetrate into the western forests. The droppings are always observed in heaps in particular spots. It is said to be fond of licking the salt efflorescence of the soil, from which habit the incisors of old individuals are often found to be much worn, and sometimes wanting altogether. —*Elliot, M. L. S. J. Oct.* 1839.

(5172) *Damalis Risia*, Hamilton Smith.—*Antelope picta*, Pallas.—*Neelgao*, Buffon and Shaw.

Maravi Can. | Ruhi, Mah.
Rojoh, Duk. |

It is found in the thick low jungles of the Rone and Chudi Pergunahs, in those of Goonjeehal near the junction of the Kistnah and Ghatparba rivers, the Mubiluhal talook, and in the Moolwar Nala towards Beejapoor, but never in the open black plains, the Mulnad, or the Ghat forests. It is comparatively rare, and is becoming more so, every day. The country people are apt to confound it with the *Sambur*; but the localities frequented by the two animals are totally different. The *Sambur* is impatient of heat, and requires shade and deep cover, the *Neelgao* is indifferent to the sun, and in the open plains, at noon, it requires a good horse and a long run to come up with it. I had a tame female of each kind for a long time in the same paddock. The *Neelgao* used to drop on its knees to feed, and attacked and defended itself by butting with the head. The *Sambur* on the other hand never knelt, and when irritated, used to rise on its hind legs, and strike with the fore-feet. In Goozerat the *Neelgao* is found in the

open, grassy plains; the herd marches in a line, the bull leading with 8 or 10 cows following.

Kar kona, CAN. | Jangli khoolga, DUK.
Gaviya, MAH. | Uana, Do,

It is somewhat remarkable that one of the largest animals of the Indian Fauna, frequenting all the extensive forest tracts from Cape Comorin to the Himalayas, should only have been indicated distinctly, within the last two years. I have seen specimens from Tinnevelly, and likewise from the whole range of the Syhadree mountains up to Mahableshwar, and I know that the animal has been killed near Vellore, in the Sherwaroyah hills near Salem, at Aseergurh, in Kandes, Rajahmundry, and I doubt not that it will likewise be found in all the deeper recesses of the eastern ghauts, and on the banks of all the great rivers passing through them. An imperfect cranium which seems to belong to a female of this species, in the United Service Museum, is labelled thus "Head of a Bison from Kuddah, Straits of Malacca, presented by Lieutenant Colonel Frith, Madras Artillery." The following memoranda were made in 1833 in the Southern Mahratta Country at a time when I had frequent opportunities of seeing the animal. "It is called *Gaviya* by the Mahrattas, *Jungli khoolga* and *Urna* by the Mahommedans (though it has not the slightest affinity with the buffalo to which both of these names apply), and *Karkona* by the Canarese, which is of similar import, from *Kadu*, a forest, and *Kona*, a buffalo, It differs also very remarkably from the common ox, and though it approaches considerably more to the description of the bison, the name generally applied to it by English sportsmen, it exhibits marked structural differences excluding it from the Bisontine group as defined by Cuvier. These consist in the plane of the forehead being "flat and even slightly concave," and in the possession of only 13 pairs of ribs. It is not improbable that it will be found to constitute a connecting link between the Bisontine and Taurine groups. The most remarkable characters in the animal are an arched coronal, or convex bony ridge, surmounting the frontal bone, and projecting beyond it so as to make the line from the vertex to the orbit a concave sweep; the continuation which form the orbit to the muzzle is slightly convex. The other distinctive mark is the prolongation of the spinous processes of the vertebræ of the back, from the withers to the loins where they cease abruptly. These processes are 12 in number and their prolongation gives the animals a very extraordinary appearance. The largest individual I met with was killed in an island of the Kala Nuddee in the district of Soonda, in 1827. A noted shikaree, the Patel or head-man of Alloor (a Hubshee or negro descendant of some of the numerous African slaves imported in the 15th century by the Mahommedan kings of Beejapoor, and who still exist as a distinct race, in this district), called us at day light and promised to show us one of the animals described by him as a wild buffalo. Crossing the river in a canoe, we struck into the forest and soon came upon a track, which he pronounced to be that of a large bull. On this he proceeded with the steadiness and sagacity of a blood hound, though it was often imperceptible to our eyes. At times when a doubt caused us to stop, he made a cast round, and on recovering the track summoned us to proceed by a loud whistle, or by imitating the cry of the spotted deer, for not a word was spoken, and the most perfect silence was enjoined. As we advanced he pointed silently to the broken boughs or other marks of the passage of a large animal, and occasionally thrust his foot into the recent dung, judging by its warmth of the vicinity of the game. We followed his steps for three miles to the river, then along the banks towards Dandelly, where the animal appeared to have passed to the other side. Wading across, we ascended the bank of a small island covered with thick underwood, and some large trees, amongst which it had lain down, about fifteen yards from where we stood. The jungle was so thick that we found it difficult to distinguish more than a great black mass among the underwood. On firing the animal got on his legs, received two balls more, and rushed into the jungle where he became very furious, and we were obliged to shelter ourselves behind the trees, to avoid the repeated charges he made, though one ball through the shoulder which had broken the bone above the elbow, prevented his moving with facility. He then became exhausted and lay down snorting loudly and rising to charge when any one approached. A ball in the forehead caused him to roll over the precipitous bank into the river. Still however he was not dead and several balls were fired into his forehead behind his ear and the junction of the head and neck without life becoming extinct, one ball which had struck the vertebræ of the neck was taken out almost pulverized. When drawn ashore and examined more minutely, the first sentiment produced in all present was astonishment at his immense bulk and size; but on measuring his height we found him much taller than his breadth at first led us to imagine. The head is very square and shorter than in the common ox, the forehead ample, the bony ridge rising about five inches in height from the plane of the frontal bone over which it inclines. When viewed behind it rises suddenly and abruptly from the nape of the neck, from whence to the vertex it measures seven inches, the horns make a wide sweep in continuation of the arched bony

ridge, and turn slightly backwards and upwards forming an angle of about 35° with the frontal bone, the whole of the head in front, above the eyes, is covered with a coat of close short hair of a light greyish brown colour, which, below the eyes, is darker, approaching almost to black. The muzzle is large and full, and of a greyish colour, the eyes are smaller than in the ox, with a fuller pupil of a pale blue colour, the ears are smaller in proportion than in the ox, the tongue is very rough and covered with prickles, the neck is short, thick and heavy, the chest broad, the shoulder very deep and muscular, the forelegs short, the joints very short and strong, the arm exceedingly large and muscular. Behind the neck and immediately above the shoulder rises a fleshy gibbosity or hump, the same height as the dorsal ridge, which is thinner and firmer, rising gradually as it goes backwards and terminates suddenly about the middle of the back. The hind quarters are lighter and lower than the fore, falling suddenly from the termination of the ridge, the tail very short, the tuft only reaching down to the hocks. The dimensions of this individual were carefully noted as follows:—

	feet.	in.
Height at the shoulder	6	1½
Do. at the rump (taken from hoof to insertion of tail), ...	5	5
Length from the nose to the insertion of the tail, ...	9	6½
Do. do. to the end of the tail which was 2 ft. 10 in., ...	12	4½
Do. of dorsal ridge including the hump, ...	3	4
Height of do. do. ...	0	4½
Girth (taken behind the forelegs), ...	8	0
Breadth of the forehead, ...	1	3½
From the muzzle to the top of the arched bony ridge, ...	2	1¾
Distance between the points of the horns, ...	2	1
Circumference of horn at base, ...	1	7½
Between the roots of horns, ...	0	13½
Length of the ear, ...	0	10½
Circumference of the neck, ...	4	4
Depth of the shoulder (from the elbow to the end of the spinal ridge), ..	4	2½
From the elbow to the knee (i. e. the fore-arm), ...	1	5¾
From the elbow to the heel,... ...	2	7
Circumference of the arm, ...	2	6

The skin on the neck and shoulder and on the thighs is very thick, being about two inches in this one, which has already shrunk from lying in the sun. It is used for making shields, which are much prized. On examining the skeleton picked clean by the vultures, we could only distinguish thirteen pairs of ribs. The cows differ from the male in having a slighter and more graceful head, a slender neck, no hump, a less defined dew-lap and the points of the horns do not turn towards each other at the points, but bend slightly backwards, the horns are smaller too, and the frontal bone narrower, but the coronal or ridge is distinctly marked. The bulls have the forehead broader in proportion to their age. In the young bull it is narrower than in the cow and the bony ridge scarcely perceptible. The horns too in the young specimen turn more upwards. The general colour is dark brown, the hair thick and short and in old individuals the upper parts are often rather bare. That on the neck and breast and beneath is longer, the skin of the throat is somewhat loose giving the appearance of a slight dew-lap. The legs are white with a rufous tint on the back and side of the forelegs. The skin of the under parts when uncovered is a deep ochrey yellow. The cow has the legs of a purer white. The breeding season is said to be early in the year and the calves are born after the rain. The bulls are often found separate from the herd which consists generally of from ten to fifteen cows and a bull. They generally feed during the night browzing on the young grass and the tender shoots of the bamboos of which they are very fond. In the morning they retire to some thicket of long grass or young bamboos where they lie down to ruminate. When disturbed the first that perceives the intruder stamps loudly with its foot to alarm the rest, and the whole rush through the forest breaking down every obstacle and forcing their way with a terrific crash,

dat euntibus ingens
Silva locum et magno cedunt virgulta fragore.
Æn. vii. 676.

When suddenly approached in the night they start off with a loud hissing snort. In 1831, I saw a young Bison calf in the possession of some Gowlees, the owners of large herds of buffaloes in the Hangul talook. It was caught when just dropt, in the month of May, and, when I saw it, was seven months old, very tame and gentle, though timid, licking the hands of the Gowlees and frisking about with the buffalo calves. It was the same colour as the old animal, very dark brown with white legs. The head small, the forehead wanting the breadth so remarkable in the adult, and the bony ridge of the crown was hardly perceptible. The horns were just beginning to sprout, the ears were larger and rounder than those of the buffalo, the eyes a pale grey or cerulean colour. The hair on the throat was long and the dew-lap slightly indicated. No hump was perceptible, but the dorsal ridge was distinctly marked. The Gowlees say they see great numbers of Bison when pasturing their herds in the neighbouring forest. They describe them as very timid and watchful, more so than any other wild animal, always reposing in a circle with their heads turned outside, ready to take alarm. They add that they see most calves from June to October but the greatest number

about August. They do not know how long the cow goes with calf, but suppose the period of gestation to be the same as that of the buffalo, or ten months and ten days The old male drives the others from the herd at the breeding season, and the single ones seen in the jungle are young males of this description, and it is probable the very old bulls are sometimes expelled also by younger and stronger males." For the following particulars derived from the observation of the animal in the Shervaroyah hills, I am indebted to Mr. Fischer. of Salem: "The Bison ordinarily frequents the hills, seeking the highest and coolest parts, but during the hottest weather, and when the hills are parched by the heat, or the grass consumed by fire, the single families, in which they commonly range the hills, congregate into large herds, and strike deep into the great woods and valleys; but after the first showers, and when verdure begins to re-appear, they again disperse, and range about freely. In wet and windy weather, they again resort to the valleys, to escape its inclemency, and also to avoid a species of fly or gnat which harasses them greatly. In the months of July and August, they regularly descend to the plains, for the purpose of licking the earth impregnated with natron or soda, which seems as essential to their well-doing as common salt is to the domestic animal when kept in hilly tracts. The chief food of the Bison seems to be the following grasses and plants:

Yadanjan cody.....	
Vallaum pilloo.....	A apecies of Saccharum, used for thatch.
Odeserengam pilloo.....	
The cottay moottoo leaf	Ricinus Communis, Castor oil Plant.
Mullum pilloo.....	Anthystiria polystachia, Roxb.
Canavam pilloo,... .../...	Sorghum muticum, Wild Cholum.
Cheevum pilloo,...	Broom grasa (Aristida).
Cattoo Corangan, leaf, ...	A species of Convolvulus Ipomœa Staphylina?

but they will eat with avidity every species of grain commonly cultivated on the hills or plains, as the ryots find to their cost. The Bison particularly is so fond of the *avaray cottay* (*Dolichos lablab*, Ainslie), Country bean, when in blossom, that they will invade, and destroy fields of it, in open daylight, in despite of any resistance the villagers can offer. In other respects it is a very inoffensive animal, very rarely attacking any one it encounters, except in the case of a single bull driven from the herd. Such a one has occasionally been known to take up his location in some deep bowery jungle, and deliberately quarter himself on the cultivation of the adjacent villages. The villagers, though ready to assist Europeans in the slaughter of Bison, will not themselves destroy them (the inviolability of the cow extending to the Bison); and so bold does this free-booting animal become in consequence, that he has been known to drive the ryots from the fields, and deliberately devour the produce. But in general it is a timid animal, and it is often difficult to get within gun shot of them. The period of gestation is with the Bison the same as with the domesticated animal; they drop their young in the months of September and October. I once had one brought to me so young the navel string was still unseparated. I should think it was then about the size of a common country cow's calf of four months old. It seems a slow growing animal. A calf I had for three years was evidently in every respect still a mere calf. They seem very difficult to rear. I have known it attempted at different ages, but never knew the animal to live beyond the third year. Mr. Cockburn has tried it in vain, in its native climate, the Sherwaroyah hills, and I have made the attempt at Salem repeatedly. At one time I had five in my farm-yard; one lived for three years: but this one, with all the others, died suddenly in the same week from some disease, marked by refusal of food, running from the nose, and an abominable stench from the mouth. A similar disease, it may be noted, prevailed, I was informed, at the same time, among the Bison of the Sherwaroyah, Shandamungalum and Neilgherry hills. The calves I had, never became in any degree domesticated: the domesticated cow could never be induced to suckle them." I may add, that the persevering ferocity of the Bison of the Sub-Himalayan range, described by Mr. Hodgson, is quite foreign to the character of the animal in the southern forests. When wounded, it is true, it charges its assailant with determined courage, and many instances have come to my knowledge of its doing so with fatal effect, among which I may cite those of two officers within the last few years, both of whom were killed at the Mahabaleshwar hills; but in general it will always seek its safety by flight, if permitted. Of a drawing of one of these it is remarked, the figure at plate 5 is taken from an indifferent sketch made of the very old bull, described at page 229, and gives a tolerable idea of the character of such an animal, though not quite correct in all its details. The dorsal ridge is too prominent; the expression of the head, particularly about the muzzle, is too heavy, and the hoofs of the hind feet are too large, this being in reality only half the size of those on the fore-feet. Plate 6 shows the crania in front and profile of another very old bull, killed on the Neilgherry hills, now in my possession; and of a young cow. The difference produced in the shape of the horns by age is distinctly shown. The great expansion of the bull's horns is entirely the effect of age, in the young males they are most erect, and the points turned to each other, while in this individual they are altogether divergent, one being half broken off, and the point of the other worn and ragged, which is always found to be the case with adult bulls. The dimension of this cranium are—

MANGANESE.

Height from the end of the maxillary bone to the vertex, ...	Inches 22
Breadth of front between the edges of the horns, ...	13 to 14
Length of horn from base to point in a straight line, ...	21
Do. do. along the curve,	30
Diameter (longest section) inside,	6½
Do. (broadest do.)... ...	4¾
Circumference at the base, ...	18⅓
Distance between the points, ...	39

The above catalogue is confined to the animals of a single province, and does not comprise the whole number of species found in Southern India; but, from the very diversified character of its surface, it includes by far the greatest proportion.—*Elliot, Madras Lit. Soc. Journal, Oct.* 1839.

(5174) MANDRAKE. ATROPA MANDRAGORA.

Usul-ul-lufah Ustrung, ARAB.	Murdum-i-geeah, PERS.
Yebrooj, BENG.	Caat-jootie, TAM.
Mandragen, GER.	
Luckmoona, Luckmoonee, GUZ. HIND.	

The fetid root of the mandrake plant has various names, arising from its fancied resemblance to the human form. It was formerly an article of the Materia Medica, but is now exploded; though the leaves are still sometimes employed in preparing anodyne fomentations.—*Ainslie. Faulkner.* It is found in many parts of the South of Europe, is of poisonous qualities and its smell is very fetid.

(5175) MANGANESE.

Bruinsteen, DUT.	Manganesia, IT.
Manganete, Magalese, Savon du Verre, FR.	Magnesia Nigra, Manganesium, LAT.
Braunstein Glasseise. GER.	Manganesia, SP.

A very brittle metal of a dusky white colour, and without either malleability or ductility. The substance known in commerce under that name, however, is the peroxide, or black oxide of the metal. It occurs native in the Mendip hills, Somerset, in the counties of Devon and Aberdeen and in many parts of India. It is found in a variety of forms; most commonly it is of an earthy appearance, and mixed with other ingredients; but sometimes, in crystals of a black colour and metallic lustre. Peroxide of Manganese is largely consumed in the manufacture of bleaching compounds; it is also used by potters and glassmakers, and in the laboratory it is considered the chéapest material from which to procure oxygen.—*Waterston. Faulkner.* Manganese occurs very abundantly in the Madras Presidency. At the Madras Exhibition of 1857, some very large samples of the *silicated sesquioxide* were exhibited by His Highness the Rajah of Vizianagrum, who contributed two tons in blocks, weighing from 2 cwt. to 3 cwt. each. The Metal was carefully examined by Dr. Scott, who reported upon the contributions sent to the Exhibition of 1855 as containing from 53 to 54 per cent of metallic manganese. The substance is well suited for glazing Pottery, along with Galena, and Felspar. A great variety of pleasing colors can be imparted to the glaze by varying the proportions of the Manganese: thus, in small quantities it gives a yellow color, in large, brown, then a blood-red, purple or black, as the proportion of Manganese is increased. It has also the property of hardening the glaze, so as to resist vinegar and weak acids: concentrated mineral acids however will corrode it. Manganese is used in small quantities by the Natives of India in giving purple, brown, and black colours to glass for Bangles. Large samples have been shipped to England for report as to its applicability to manufacturing purposes. Some good samples of the same ore were forwarded from Kurnool, and Toomkoor in Mysore.

Peroxide of Manganese.—This substance, which occurs in the form of a compact black stone, with a smutty brown or black powder on the surface, is of more value than the preceding, being largely employed for manufacturing purposes. Good but small samples have been forwarded from Soondoor, and from Roodrar in the Coilcoontlah Talook, Cuddapah: as also from Bimlipatam. A specimen from the latter locality examined by Dr. Scott contained about 30 per cent of peroxide, which, although impure, would certainly be of some commercial value. Another specimen from Bellary was also found to contain a good deal of the Peroxide. Brown wad and brown fibrous Manganese were exhibited from the Red Hills, Bangalore and Cuddapah, ores of Manganese occur at the Neilgherries. Many of the Iron ores and Iron sands contain Manganese. —*M. E. J. R.* Captain Tremenheere has given a full report on the manganese of Mergui, on the Tenasserim; and Mr. Mason has seen specimens of manganese mixed with iron from one of the islands south of Mergui. Captain Tremenheere wrote: "During my stay at the Tenasserim coal basin, a piece of manganese ore, (black wad), of good quality, was brought to me by a Karen, who stated, that it had been found accidentally in the bank of a stream called the Thuggoo, which enters the Great Tenasserim, seventeen miles below the coal site. Subsequently, several other pieces of the same ore were brought to Mr. T. A Corbin, Assistant to the Commissioner from the the Therabuen river, five miles above the Thuggoo, and from an intermediate spot, the locality of which have been previously known, and had been, I believe, originally pointed out by Lieutenant Glover of the Madras Army. In proceeding down the river, I visited these spots, and found at each, that a valuable bed of manganese ore existed close to the surface of the country. It had been apparently cut through by

the action of the stream and river before mentioned, leaving a section of the bed of ore in their banks, covered only by the debris of the banks themselves, Large quantities might have been carried away, but a few hand specimens only were taken, which sufficiently shew the nature of the deposit, and fair samples of what might be easily collected. Of the extent of these manganese beds it is difficult to pronounce. The face of the country in which they are situated is flat, thickly overved with soil, and with the densest jungle. It is not, as far as I could perceive, intersected by many streams which would afford the means of tracing the mineral deposit. The Great Tenasserim river has passed through the manganese bed in one spot, 2½ miles removed from two other points at which it occurs to the north and south, at both of which it is likewise discovered near the surface by the action of the streams Thuggoo and Therabuen. The probability therefore, is, that it is a horizontal deposit covering many square miles, But without indulging in conjecture, there is sufficient at the localities referred to, to indicate large quanties of manganese ore which could be collected by penetrating through the soil lying above it, and immediately near the spots in which it is now exposed to the day. It occurs in the form of the black oxide, and is the manganese of commerce. It is largely consumed in Europe in the preparation of bleaching compounds, and when pure, is valuable to the manufacturer of glass. The soft black ore, No. 1, is a hydrate of the peroxide of manganese, known under the name of wad. It contains of water two equivalents, or 29 per cent: Iron, 196 grains by analysis; its specific gravity is 1.47. The specific gravity of the grey peroxide, No 4, is 1. 46."—*Mason.*

(5176) MANGEL WURZEL, FIELD BEET.

Betteraves. FR.	Bietola. IT.
Mangold Wurzel, GER.	

A variety between the red and white beet. It has been a good deal cultivated in France, Germany, and Switzerland, partly as food for cattle. and partly to be used in distillation, and in the extraction of sugar. Its culture, in Great Britain is recent, dating only from the end of the last century, and is employed almost entirely in the fattening of stock, and the feeding of milch cows.—*Faulkner*

(5177) MANGIFERA, a genus of Plants belonging to the natural order *Anacardiaceæ*. Three or four species of this genus are enumerated—as *M. fœtida* of Loureiro, a native of Cochin China and the Moluccas; *M. laxiflora*, indigenous in Mauritius; and *M. sylvatica* of Roxburgh, a native of the hilly districts bordering on Silhet, where it grows to a great size, and is called Fukshmee-Am. It bears a fruit which ripens in February and March, and is eaten by the natives, though not so palatable as even a bad mango. It is also dried and kept by them for medicinal purposes. *M. oppositifolia*, Roxburgh, a native of Rangoon, is proposed by Messrs, Wight and Arnott to be formed into a distinct genus.

(5178) MANGIFERA ATTENUATA.

Tawsa-thayet. BURM.

Scarce, but found in the Pegu and Toungkoo Forests: bark brown.—*McClelland.*

(5179) MANGIFERA FÆTIDA, HORSE MANGO. This is a large mango multiplied at Mergui, and quite a favorite with the natives. It has an odour resembling the dorian, and like that has been introduced from the Straits.—*Mason.*

(5180) MANGIFERA INDICA.

Am, BENG.	Mampalam, MALAY.
Mango, ENG.	Kapalam, LAMPUNG.
Maumedee Chettoo, TEL.	Palam, JAV.
Mango maram, TAM.	Mavena, CAN.

A tree of large growth, and generally diffused all over India, and in all the warmer parts of Asia. Is generally raised from seed though sometimes by layers or grafting by approach which are the only methods of certainly continuing a good sort, probably of improving them. The stones must be sown soon after they are taken from the fruit, otherwise they do not vegetate, but there is no depending on the quality of the fruit so raised The seed of a very superior sort will produce fruit of a bad kind. Flowering time January, February and March: the fruit is ripe in May, June and July. The kernels are large and seem to contain much nourishment, however, they are made no use of excepting during times of scarcity and famine, they are then boiled in the steam of water and used as an article of diet. The wood is of a dull gray colour, porous, yet pretty durable if kept dry, but soon decays if exposed to wet, of the effect of which it is very sensitive. In very large old trees it acquires a light chocolate colour towards the centre of the trunk, and larger branches. This is hard, closer grained and much more durable. It is generally used for constructing Massoolah boats and for packing cases, the cabinet makers at Madras prefer it to other wood for veneering on: it is also generally used where common light wood is required by Coach builders, Cabinet makers and others, being the cheapest wood obtained.—*Rohde M.S.S.* The wood has the property of holding a nail faster than any other wood I know, as those may have found who have to open chests of indigo, &c. it is one of the most common woods for backs and linings of furniture in Madras. —*Rohde.* Of this genus, the Mango-Tree, is alone of any consequence, and this as forming one of the most grateful fruits of the tro-

pical parts of Asia; it extends also as far north as 30°, and has been successfully introduced into the west Indies. The tree grows to a great size, with an erect trunk, and dark-coloured cracked bark. The wood is of a whitish or dull-grey colour, porous, yet pretty durable if kept dry. The leaves are alternate, petioled, lanceolar, entire, often a little waved at the margins, firm, smooth, shining, and having, when bruised, a pleasant resinous smell. The flowers are yellow coloured, and small, but produced in great numbers, on large terminal erect panicles. Many perfect male flowers are often found intermixed with the hermaphrodite ones. Calyx 5-leaved; petals 5, lanceolate, twice the length of the calyx, furnished in the inside with a lobed granular scale or crust; stamen, a single fertile one, with three or four filament like bodies, which represent the abortive stamens; ovary with its base immersed in the torus, obliquely oval, 1-celled, with a single ovule attached to the side of the cell; style one, from the upper edge of the ovary, curved downwards; drupe oblong, or somewhat kidney-formed, also a little compressed like a kidney, fleshy, with smooth rind, yellow or reddish when ripe, size varies, but in general about as large as a goose's egg; nut conformable to the drupe, but compressed, woody, 1-celled, 2-valved, covered on the outside with many fibrous filaments, particularly in the worst sorts; the kernels are large. Embryo between erect and transverse; cotyledons thick, fleshy; radicle opposite to hilum. The Mango is so well known as one of the most highly esteemed fruits of the East, that one is surprised to find it sometimes described as like nothing so much as a mixture of tow and turpentine. The latter is a secretion abounding in the family to which the Mango belongs, and may be secreted in larger quantities in neglected varieties, where also the filaments of the nut will likewise abound. But in well cultivated varieties the fruit is sweet and rich-flavoured, juicy, and nearly as free of fibres as a melon. The kernels contain much nourishment, but are never used for food except in famines, when they are cooked in the steam of water, and used as an article of diet. From wounds made in the bark of the tree there issues a soft reddish-brown resin, which ago hardens. Burnt in a candle, it emits a smell like that of a Cashew nut when roasting. It softens in the mouth, and adheres to the teeth. The taste is slightly bitter, with some degree of pungency. It dissolves almost entirely in spirits, and to some degree in water. The tree is generally raised from seeds which should be sown soon after they are gathered, but this is a very uncertain way of getting the finer varieties. Propagating by layers, and grafting by approach, are the only modes of certainly continuing the sorts, as well as of improving them. These have the advantage also of bearing when small in size, that is, only a few feet in height, and therefore well suited to culture in the hothouses of Europe. Sweet states "that the Mango ripens in England when the plants are of a good size. Sandy loam, or a mixture of loam and peat, is most suitable to it; and the pits should be well drained, as the plants are apt to get sodden with too much water. Fresh seeds from the West Indies vegetate freely. The plant may also be increased from cuttings, which root best in sand under a hand glass." It would be advisable also to imitate its native climate as much as possible, that is, after winter, giving it dry heat with watering for some months, and then removing it into an orchideous house in the season of ripening its fruit.—*Eng. Cyc.*

(5181) MANGIFERA. SPONDIAS MANGIFERA. Lin.

Wild Mango, Eng.	Cat Ambalam, Hort Mal.
Caat Maam pullum Tam.	Canana Amra. Sans.
Junglie Aam, Duk.	Adivie Mamedie pundoo Tel.
Condondong, Rumph.	

This fruit has got its name from its resemblance to a Mango. It is harsh and little deserving of notice. Rheede informs us that on the Malabar coast, the root of the tree is considered as emmenagogue that the bark is supposed to be of use in dysenteric affections and that a decoction of the wood is serviceable in gonorrhœa.—*Ainslie p.* 222.

(5182) MANGLETIA, a genus of Plants belonging to the natural order *Magnoliaceæ*, one of the species of which, *M. glauca*, has a white solid wood, which is largely employed in Java, and supposed to prevent the decay of corpses put into coffins made of it.—*Eng. Cyc.*

Ainslie's Mat. Med. p, 260.

Of this fruit there is a great variety in India. Two of the most esteemed sorts are the Alphonso and the Massagong. The practice of engrafting the Mango, as first introduced at Madras, some years ago, by the late Dr. James Anderson, and since so happily followed up by Mr. Andrews and others, has improved it in so great a degree as to have gained it, and perhaps, justly, the title of "The finest of all fruits." Rumphius is of opinion that Mangoes heat the blood and produce exanthematous affections. Vide Rumphius Tom. I. Cap. XXI page 95.—*Ainslie, p.* 226. The far-famed and delicious fruit of the *Mangifera Indica* is plentiful in Bombay, the Concans, Deccan, &c. Those produced in Bombay and its immediate vicinity are held in greatest

repute. The fruit, when ripe, is served up at dessert, and when green, is used for making preserves, pickles, tarts, &c.—*Faulkner.* The Mango may be procured twice in the year only, in Bombay. Propagation may easily be effected by seed and cuttings, &c.; but the process is slow, as a tree thus raised will not bear fruit before the 5th or 6th year, whereas those that are grafted produce in the 2d or 3d, although it is injurious to the tree to let it bear so early, and the blossoms should be removed. Young grafts will sometimes, indeed very often, blossom the first season they are removed, and if allowed to bear fruit, it checks them for a length of time after. A mango graft may be applied at any time of the year, but the stock must be kept continually moist by watering. When the graft and stock have become united, the former must be partially divided by a notch with a sharp knife: this may be done after six weeks have elapsed from the time of its first being united: a second cutting may be effected a fortnight later, and the complete removal from the parent tree at the expiration of nine or ten weeks. After this, remove the graft into the shade for a fortnight longer, when it may be put into the spot where it is to remain. A graft tree never attains the size of a seedling, neither will it continue to live or bear so long, and it is doubted if the seed of a graft mango would produce the same fruit, whereas a seedling often does so. The time that a seedling takes to produce fruit is the great objection to this mode of rearing trees: nevertheless a young tree of three years old might have one of its branches brought into blossom by ringing; this would enable the cultivator to judge if the tree was worth preserving or not. The finest flavoured sorts of Mango grown in Western India, are the Alphonso, Raspberry, Mazagon, Doriah, and Malgrobah: this latter variety is of a greenish tinge inside when ripe, and by far the largest of the whole, being three times the size of an Alphonso; and it ripens the last. When the graft is planted out, it requires only a moderate proportion of care, clearing the ground of all weeds, and removing any buds that shew themselves. Within the space from the ground to where the first branches are to rise from, all superfluous and weak shoots should be removed, more particularly those from the centre of the tree, as also all branches that trail on the ground, unless required for grafting from. The tree is better for being pruned, and whenever the interior of a tree may contain superfluous branches or when there is not sufficient room for the growth of the young and fruit bearing shoots, a clear space must be provided,—and this can only be done by pruning. The best time for this operation is soon after the tree has done bearing fruit. No old and decayed wood should be allowed to remain, and great care be taken to remove on the first appearance the Borer, should they indicate their presence by their appearance on the bark. When trees are old and have their bark injured, it must be all cleared away, and the parts covered with the composition recommended for that purpose. Dr. Riddell was favoured with the following information from a friend at Aurungabad. Take slips from the healthy branch of a mangoe, at least two feet long, taking care to cut it one inch above the joint at the top and the same below the joint at the bottom. The cuttings will not all be equal, as in some branches the joints are short and in others long. The thickness of the slip is to be from three quarters to three inches in diameter. Half the length of the slip is to be slightly punctured with an awl, and then inserted into the ground to that depth (half of the slip) perfectly perpendicular; and then make a knob at the top of the slip with plain cowdung. The cuttings must be well watered in such a manner as to keep up an uninterrupted moisture in the ground; and moreover the cutting are to be well shaded, and the coverings only to be removed by degrees as the plants attain leaves and strength, and not to be transplanted on any account until the next monsoon. The slips begin to bud within a month generally, but sometimes take a much longer period. In all cases the punctures are indispensably necessary, to admit of root fibres being thrown out from them, The tree and fruit may both be improved, if, during the cold season, the ground is dug all round the roots, and by the addition of a suitable quantity of good old manure. The seed will only grow when fresh, and seldom after six weeks. From twenty to twenty-four feet of space should be allowed between each tree if a graft: double the space is required for a seedling.—*Riddell.* The Mango deserves the first place among the indigenous fruits, of Tennasserim, being, as Mr. Lindley truly says, "to the inhabitants of India what the peach is to Europeans; the most grateful of all fruits. Its flesh is filled with a rich luscious juice; but the inferior kinds have also so much turpentine flavour as to be uneatable." Unfortunately, Tenasserim Mangoes are notoriously inferior; and to say nothing of the turpentine flavor that some of them occasionally have, half, if not three fourths of all that are sold in the bazar, are worm eaten, though that is not at all apparent, when they are bought. There are two different species, Mangifera indica, and M. sylvatica, both of which the natives say grow wild, and several varieties are cultivated in the Provinces. The finest is a variety from Siam, which produces a large fruit with a very thin stone.—*Mason.* This fruit is very plentiful throughout Pegu, but more especially in the Thanwaddy and Toungboo districts.—*M'Clelland.*

(5164) MANGO FISH, POLYNEMUS PARA-

DISEUS. R. Rasul. This is a splendid fish and a favorite with many. It is nearly related to the mullets, and remarkable for the long filaments to the pectoral fins.—*Mason.*

(5185) MANGO-PICKLES, are much in use, amongst both Europeans and Natives. Take about 300 green mangoes, divide into two, and dry in the sun for three days:

Take of Turmeric, ...	4½ oz.	
Garlic, ...	3 „	3 drs.
Salt, ...	6 lbs.	
Mustard, ...	1½ oz.	

Coriander seed toasted oz. 1½: mix the spices together, and lay the mixture in alternate layers with the mangoes; and add 9 oz. of gingelly oil —*Herklots.* Indeed the green fruit of the Mango is used in making chatnies, pickles and curries. In the Bombay Territories, the mangoes when full grown are cut into slices, dried in the sun and preserved, they form an article of commerce; used in acidulating curries, mulligatawnies, &c. —*Jaffery.*

(5186) MANGOSTIN. GARCINIA MANGOSTANA.

Manggusta, MAL.	Manggis, BALI. JAV.
Manggos, LAM.	Manggisi, BUGIS.
Mangu, SUND.	

According to Crawfurd, p. 265, The plant which produces this famed fruit has not been traced to any of the Garcinias, as the parent stock, the plant is about the size of a cherry tree and very handsome. It grows in perfection as far as 14° N. of the equator and 7° south of it. A congenial proportion of heat and moisture throughout the year seems much more requisite than soil or latitude for the successful growth of this fruit.—*Crawfurd's Dict.* "Malaya's nectared mangosteen" is truly a delicious fruit, and by many esteemed as "the most palatable of known fruits," but though very delicate it is not to be compared to an American peach. It is cultivated to a considerable extent in Mergui, but is rarely seen in the northern Provinces.—*Mason.*

(5187) MANGROVE. RHIZOPHORA. Mangrove abounds on the coasts of the Bay of Bengal; the Indian Islands and at the mouth of the Indus. Its bark is employed in tanning. In the West Indies, cordage is made of the bark of a species of Mangrove, which is hence called Rope Mangrove. Its bark has been used for tanning purposes, for which it is probably more suitable than for cordage.—*Royle, Fib. Pl. p.* 301. The species of mangrove most abundant along the Tenasserim shores furnishes a hard and durable timber. The tree is easily distinguished from its associates, for it drops no roots from its branches, but the trunk is divided into numerous roots for half its height, like a small bamboo pavilion.—*Mason.*

(5188) MANGROVE MORDANT. The bark of a small tree from the mangrove swamps is used by the Tavoy women in dyeing red, but Mr. Mason thinks as a mordant.—*Mason.*

(5189) *Rhizophora gymnorhiza.*

Kayu-api-api, MAL.

Is used for fuel in the Indian Archipelago.

(5190) *Rhizophira mangle.* Common or black mangrove grows in the Indian Archipelago, and is used in tanning, its wood gives a red dye.—*Crawfurd, page* 266. The tree forms a striking feature in the physical geography of the Archipelago and does indeed of all tropical countries, for a belt of it as deep as the reach of the tide is always found wherever there is a shallow and muddy shore. The tree which rises to the height of forty or fifty feet is invariably found in such situations, constituting a dense, and almost impenetrable forest. Each tree stands on a cradle of its own roots from five to six feet high, bare at low water covered so as to give the appearance of trees growing in the sea. The mangrove jungle is the favorite resort of musquitos and crocodiles, and affords a convenient and almost inaccessible retreat to the pirate.—*Crawfurd*, 266.

(5191) MANGROVE BARK (RHIZOPHORA MANGLE), is used to dye chocolate color in the East and West Indies. This was one of the colors introduced by Dr. Bancroft, and for the exclusive use of which he obtained an Act of Parliament. It is procured in plenty at Arracan, Malabar, and Singapore in the East—*Mason.*

(5192) MANGO-GINGER. [CURCUMA.]

(5193) MANGO-TREE. [MANGIFERA.]

(5194) MANGOSTEEN. [CLUSIACEÆ.] GARCINIA.]

(5195) MANGOUSTE. [HERPESTES.]

(5196) MANGROVE. [RHIZOPHORA.]

(5197) MANIHOT. [JATROPHA.]

(5198) MANIOC. [CASSAVA.]

(5199) MANIS. [MAMMALIA.]

(5200) MANNA.

Mun, Terunjabeen. ARAB.	Manna, IT.
Manna, DUT.	Gambing, JAV.
Manne, FR.	Sheer-i khist, PERS.
Mannaesche, GER.	Manna, PORT.
Sheer-Khist, GUZ. HIND.	Kapurrimba, MAL.

The concrete juice of the *Ornus Europeus*, a species of Ash, native of the south of Europe. Other sweetish secretions exuded by some other plants are usually considered to be kinds of Manna. These appear to be all produced in warm and dry parts of the world. The kind which is most abundant is by the Arabs called Toorunjbeen, which is often translated 'Persian Manna,' and is produced by the thorny plant, called by botanists *Alhagi Maurorum*. The genus *Alhagi* (a name compounded of haj' and the article al) of botanists contains two species, *A. Maurorum* and *A. desertorum*, found in India

Egypt, Arabia, the north of Persia, and Syria. Both species are also called Oushturkhar, or Camel's Thorn. *A. Maurorum* is alone remarkable for yielding a kind of Manna, which by some authors has been supposed to be the Manna of the Wilderness; hence the plant itself was called *Manna Hebraica* by Mr. Don. The climate of Persia and Bokhara seems alone suited for the secretion of this Manna, which in the latter country is employed as a substitute for sugar, and is imported into India from Cabul and Khorassan. A second kind, which, though less abundant, is more esteemed than the former, is called Sheer Khisht, and is mentioned by Garcias under this name, and described as produced in the country of the Uzbecs. A Cabul merchant reported to Dr. Royle that it was produced by a tree called Gundeleh, which was about 12 feet high, had a jointed stem, and grew in Candahar. A third kind of Manna is called Guzunjbeen, the produce of a species of Tamarisk, called Guz, which is considered by Ehrenberg to be only a variety of *Tamariscus gallica*, growing on Mount Sinai, but which has been called *T. mannifera*: by some authors this is supposed to be the Manna of the Wilderness. It is said to be produced also in Laristan and in Irak Ajemi. A fourth kind of Manna is produced on *Calotropis procera*, called Ashur, and its sweet exudation or sugar Shukur-al-Ashur, under which name it is described by Avicenna; Zuccarun-al-Husur in the Latin translation, ch. 758. A fifth kind, called Bed-Khisht, is described in Persian works as being produced on a species of willow in Persian Khorassan. Besides these comparatively little known kinds of Manna, a sweetish exudation is produced on the Larch (*Larix Europæa*), which forms the *Manna Brigantiaca*, or Briancon Manna of some Pharmacopœas. [ORNUS; ALHAGI; TAMARISCUS; LARIX].—*Eng. Cyc.* There is a tree scattered on the Baien mountains, which in the dry season exudes a sweet substance resembling the manna of the shops. Mr. Mason observed it in some instances, where it had dropped from the branches all around the base of a large tree like rain; and again, where it had gushed out of the trunk like a large mass of gum arabic. He had never seen the tree either in flower, or fruit, but thinks it belongs to the myrtle tribe, a family that produces manna in New Holland.—*Mason.* According to Dr. Royle, the word manna seems to be derived from the Arabic *mun*, signifying the same thing. But as there are several other sweetish exudations (*v.* Manna, *Penny Cycl.*), it is difficult to determine when Manna was first known and used.—*Royle.* Capt. Drury however says, that the way the word manna came first to signify what we now understand by that name, was solely from an erroneous translation of Exodus xvi. 15, which runs thus: "And when the children of Israel saw it, they said to one another, 'It is manna,' for they wist not what it was." So clear a contradiction in the text does not require to be pointed out. The fact is that the words in the original were *Man-hu*, meaning What is it? which, instead of being correctly rendered, was given us, 'It is *Man-hu*,' or manger, an error which has been preserved in our version of the Septuagint to the present time.—*Useful Plants.*

(5201) MANTIDÆ, a family of Orthopterous Insects, the species of which may be distinguished by the following characters:—Head exposed (not hidden by the thorax), furnished with three ocelli, or simple eyes, besides the ordinary pair of compound eyes; palpi short slender and cylindrical; antennæ generally setaceous, but sometimes pectinated; short in the females and long in the males; body elongated; the thorax usually very long, often dilated at the sides and dentate; abdomen long, and with the terminal segment small in the male sex, more or less dilated, and with this terminal segment large in the females; the apex furnished with two small appendages; legs long; the four posterior legs slender, the anterior legs with the coxæ very large and elongated; the femora also very large, dilated, and furnished with a double series of spines on the under side, between which (when the animal is in a state of repose) the tibiæ are placed: the tibiæ are rather short, armed with spines, and having a strong spine at the apex, which is recurved; tarsi usually 5-jointed, but in some species the posterior tarsi have only three joints; wings horizontally folded when at rest. The principal genera contained in this family are:—*Heteromytarsus*, *Eremiaphila*, and *Mantis*. The *Mantidæ* are found in all warm countries, are exceedingly numerous, and remarkable for the grotesque forms which they usually assume. Their resemblance to a portion of a plant is often so great, that it is only by their motions they can be discovered. The names *M. religiosa*, *M. precaria*, *M. sancta*, Praying Mantis, &c. have been applied to certain species on account of a peculiarity in their habits—that of erecting the thorax at an angle with the body, and placing together the large fore-legs, like the hands of a person engaged in prayer; in this position they will sometimes remain perfectly motionless for several hours. Their food consists of flies and other insects, which they are exceedingly dexterous in catching by means of their fore-legs; the prey is held by the fore-leg by bending back the tibia against the femur; the opposing surfaces of these two portions of the legs being covered with spines, enable them to retain their prey in this manner, and to convey it to the mouth. The eggs are deposited by the female *Mantis* upon plants, and are [illegible] by a glutinous substance, which [illegible] hard and forms a kind of case, in which [illegible] are arranged in a symmetrical manner. The form of the case varies according to the species. The

ning, when hatched, resemble the parents, except in size and in being destitute of wings. *Lantis gingalica* illustrates a common form of the insects of the present family. This insect inhabits the East Indies, and when live is of a green colour. The female is about 4 inches, and the male is 3½ inches in length.—*Eng. Cyc.*

(5202) MANILLA NUT. [GROUND NUT, ARACHIS HYPOGEA.]

(5203) MANILLA HEMP. MUSA TEXTILIS. The power possessed by this fibre of bearing great strains, as well as being very durable, lighter, and also cheaper than Russian Hemp, has latterly attracted much attention to it and it has been much employed for cordage of various kinds, especially those required to bear considerable strain. Many American vessels have the whole of their rigging made of it, and when worn out it can be converted into an excellent quality of paper. The plant which yields this hemp was formerly introduced by Dr. Roxbourgh into the Northern Circars, and Lord Harris has recently made a second effort to obtain a supply of its roots. It is a native of the Philippine Islands where it is called "abaca" and by the Bisayas "Lamot," but there are several varieties known here under different names. The Abaca brava, or wild abaca, is called by the Bicoles, Agotai, the fibres of the mountain abaca only serve for making ropes, which are called by them "Agotag" or Amoquid." The Sagig and "Laquis" of the Bisayas are other varieties. Rumphius states that the Malay name of the "Laquis" is Pissang Utan," thus it is called in Amboyna Kula abbal; in Ternate "Fana"; and in Mindinano "Coffo": also the cloth made from it. The "abaca" is abundant in the volcanic region of the Philippine Islands from Luzon to Mindinao, as also in the neighbouring Islands as far south as the Moluccas. It therefore extends from the Equator to 20° North, and may, probably, be easily cultivated in Travancore, Arracan, Assam and Northern Circars. The "Abaca" should be cut when 18 months old, just before its flowering or fructification appears, at which period the fibres are shorter and finer and they are said to became weaker afterwards. It is cut near the roots, and the leaves cut off first before their expansion: it is then slit open longitudinally and the sheathing fibers removed, as it is from them that the fibres are formed as in all the plantains. The fibres from the outer layers are harder and stronger, and form the "bandala" of commerce, which is employed in the fabrication of cordage. The finer fibres from the inner layers are called lupis, and the "nipis" and other delicate fabrics are made from them: while the intermediate layers produce the "tupos" which are made into cloths and gauzes of different degrees of fineness, and four yards long, and are universally used as clothing. Dr. Hunter's general principles of cleaning explained under the head of fibres, is doubtless well capable of application here, and it is hoped that Lord Harris' present effort to introduce so useful a fibrous plant may be successful. When well scraped, shaken and washed, they require to be dried and picked; those for cordage require no further preparation, but the fibres to be employed by the weavers, are made up into a bundle and made soft and pliant by beatings with a wooden mallet, and their ends are then gummed together as is done with pine apple fibre, and they are rolled up for the loom. The stuffs, when woven, are soaked in warm water, (or lime water) for 24 hours, after which they are soaked in cold water then put into rice water and lastly washed as before, by which means they acquire lustre, softness and a white colour. Some are dyed into blue red colours, some are embroidered: and they seem in Europe to be confounded with grass cloth. Manilla Rope is sold in England at a nett price of £ 32 per ton, on the average of the ten years prior to 1852; but it rose in that year to £ 44 and £ 50 for the average kinds, and in the rise in 1854 it was quoted at £70 to £76. Dr. Oxley of Singapore states that the Musa textilis grows freely in Singapore. See MUSA.

(5204) MANILLA DRAGON CANES. The white and brown Manilla Dragon's canes of commerce are supposed to be made from the stem of the Calamus Draco, the Dragons' blood Palm.

(5205) MARANDA, the *Tamil* name of a tree which is very heavy and close grained. It is one of the best sorts of Ceylon wood; of a dark-brown colour, and grows to about twenty inches in diameter, and twenty feet in height.—*Edye. Cey.*

(5206) MARATINA, the Tamil name of a tree which grows to about twenty inches in diameter, and from fifteen to twenty feet in height. It is sometimes used by the natives for house and boat-work.—*Edye. Ceylon.*

(5207) MARABOU. [CICONIA.]

(5208) MARANTA, a genus of Plants belonging to the natural order *Marantaceæ*. The root stock is white, horizontal, annulated, from which proceed root-fibres, some of which swell into tubers and become jointed stocks, similar to the rhizoma, but covered with scales. These often elongate, curve upwards, and rising out of the ground become new plants. The stem is 2 or 6 feet high, much branched, slender, finely hairy, tumid at the joints; leaves alternate, with long leafy hairy sheaths, ovate-lanceolate; panicles terminal, lax, spreading, with long linear sheathing bracts at the ramifications; calyx green and smooth; corolla white, small, unequal, one of the inner segments in the form of a lip; anther attached to the petaloid filament; style hooded, petal-shaped; ovary 3-celled, smooth; stigma 3-sided; fruit even, dry, 1-seeded.—*Eng. Cyc.*

(5209) **MARANTA ARUNDINACEA** yields the arrow-root of commerce, but it is also procured in large quantities from a variety of closely-allied, and even many distinct, plants. Thus the Surinam and Bermuda arrow-root is the produce of the *M. arundinacea*, while the Jamaica arrow-root is obtained from the *M. Indica* (Tussac); which plant, along with several Curcumas, yields also the East Indian arrow-root. The West Indian arrow-root has mostly a pure white colour, the East Indian a yellow tinge. The tubers, root-stocks, or offsets, are grated or bruised and repeatedly washed with water, which is passed through a fine hair-sieve, so long as it runs off with a milky appearance. It is allowed to subside, the supernatant water drained off, and the powder dried: 100 parts of the fresh plant yield 10 parts of arrow-root; but Benzon states 100 parts to yield 23 or 26 parts. According to the analysis of this chemist it consists of —

Volatile oil, ...	0·07
Starch, ...	26·00
Vegetable Albumen, ...	1·58
Gummy Extract, ...	0·60
Chloride of Calcium, insoluble fibre, ...	6·00
Water, ...	65·60
	99·85

The volatile oil imparts a slight odour to the solution in warm water which helps to distinguish genuine arrow-root from several of the articles substituted for it. Maranta Arrow-root has scarcely any taste, being bland and insipid; the powder, when pressed in the hand, emits a crackling noise, and retains the impression of the fingers, which common starch from wheat does not. Cassava (Manioc, from *Jatropha*, or *Janipha Manihot*) also retains the impression of the fingers, but it has more odour and a somewhat acrid taste. The meals of any cereal grain may easily be distinguished from arrow root by the nitrogen which they contain, and the ammoniacal products which they yield by distillation. Potato-starch is however most frequently used to adulterate arrow-root, or a substitute for it. Microscopic observation of the form and size of the grains will point out the difference, as first indicated by Raspail (Annales des Sciences Nat.,' t. v.), those of arrow-root being smaller; the different habitudes of the starch with reagents will also do this. (See Messrs. Payen et Chevalier, 'Traite de la Pomme de Terre,' p. 126; also 'Journal de Pharmacie,' Aout, 1833.) Potato-starch is not soluble in cold water, which is the case with arrow-root. Dissolved in absolute alcohol, arrow-root separates into two distinct portions, which neither wheat nor potato-starch does. In equal proportions dissolved in warm water, arrow-root yields a thinner solution, with a more slimy aspect than wheat-starch. Arrow-root dissolved in water, milk, or any other appropriate vehicle,

MARANTA ARUNDINACEA.

constitutes, from its easy digestibility, a most excellent article of diet for delicate persons and young children. It may be given plain, or with wine or spices, according to circumstances. The valuable property just mentioned does not belong to either wheat or potato-starch. The latter, if prepared from potatoes in spring, is very liable to disturb the stomach; but less so if prepared in October or November. Potato-starch may be prepared at a very cheap rate, and kept for a long period unchanged, thus affording a protection against times of scarcity. (Sir John Sinclair, *On the Culture and Use of Potatoes*, Edinb., 1828. — *Eng. Cyc.* In India, *Maranta arundinacea* has been sucessfully cultivated near Calcutta. Some Arrow-root is yielded by another species, *M. ramosissima*. Besides these, much is yielded by *Curcuma angustifolia*, *leucorhiza*, *rubescens* &c.; but the greater portion of the Arrow-root which is exported is produced in Travancore, and we have no information respecting the species which yields it as *Curcuma angustifolia* has not been proved to be indigenous there. Some is also made in India from the tubers of *Ipomea batatas*. The Arundinacea plants are propagated by parting the roots; a light loamy soil is most favourable to their growth; when a year old they are fit for use, being taken out of the ground they are washed, and either grated or pounded, in this state the pulp is put into and intimately mixed with water, which washes the farinacious parts from the fibrous which is thrown aside, the white turbid fluid is strained to free it from all fibrous particles and is left for the starchy matter to subside, the supernatant liquor is then drawn off, fresh water is again added, the mixture left at rest, and the water poured off as before, this process may be repeated. The starch being left in a state of purity, the moisture is evaporated by placing it on clean cloths and exposing it to the sun's influence, when thoroughly dried it is fit for use. — *Rohde*. Maranta arrow-root says, Hassal, is obtained from the rhizomes of the Maranta arundinacea. A rhizome is an under ground jointed stem placed horizontally in the earth, giving off from its upper surface, branches, and from the lower, roots: the starch or fecula is contained in the joints of the rhizome, being deposited in innumerable minute cells. The following account of its preparation is given by Dr. Pereira in the new and greatly improved edition of his "Materia Medica." — "The starch, or fecula, is extracted from the roots (tubers), when these are about ten or twelve months old. The process is entirely a mechanical one, and is performed either by hand or by machine.

"*In Jamaica*, it is procured as follows: — The tubers are dug up, well washed in water, and then beaten in large, deep, wooden mortars to a pulp, this is thrown into a large tub of clean water. The whole is then well stirred, and

e fibrous part being cut out by the hands and rown away. The milky liquor being passed rough a hair sieve, or canvas cloth, is suffered settle, and the clear water is drained off. At e bottom of the vessel is a white mass which again mixed with clean water, and drained; ain dry, the mass is dried on sheets in the sun and pure starch.

In Bermuda, the roots are first deprived of eir paper-like scales and then rasped by the id of wheel-rasp, and the fecula well washed rough sieves and carefully dried.

In St. Vincent, upon the Hopewell estate, in is island, the carefully skinned tubers are wash-l, then ground in a mill, and the pulp washed in nned copper cylindrical washing machines. The cula is subsequently dried in drying-houses. In der to obtain the fecula free from impurity, re water must be used, and great care and tention paid in every step of the process. The inning or peeling of the tubers must be per-rmed with great nicety as the cuticle contains resinous matter, which imparts colour and a sagreeable flavour to the starch. German silver dettes are used for skimming the deposited cula, and shovels of the same metal for packing ie dried fecula. The drying is effected in pans overed by white gauze to exclude dust and in-ects." Pure and unadulterated Maranta arrow-ot should be of a dull and opaque white-colour, epitating or crackling when pressed between ie fingers, and treated with about twice its eight of concentrated hydrochloric acid it should eld an opaque paste. The above characters id appearances may all, however, be as-umed by certain of the other arrow roots; ie microscope, therefore, affords the only ready id certain means of distinguishing this arrow-ot from all other species, and these again from ch other. The appellations which have been estowed upon Maranta arrow-root are very nu-erous, their use ought to be wholly discontinu-l for the reasons already assigned; thus it is metimes called West India arrow-root, Jamaica, emerara, Bermuda, Berbice, St. Vincent arrow-ot, &c. The impropriety of denominating it est India arrow-root is shown by the circum-ance that the Maranta plant is cultivated in e East as well as the West Indies.

Curcuma arrow-root, is obtained from the ubers of Curcuma angustifolia one of the family f the Zingiberaceæ. The mode of its prepa-ation does not differ materially from that mployed in obtaining the fecula from the ubers of Maranta arundinacea, and which has eady been described. Two qualities of urcuma arrow-root are imported into great ritain from the East Indies, principally from alcutta a white and a brown variety. The hite is the best; the powder when pressed etween the fingers feels less firm and does not repitate to the same extent as Maranta arrow-root, the two species can however be distinguished from each other only with certainty by means of the microscope.

Tacca arrow-root, is obtained from the tubers of the Tacca oceanica, a native of the South Sea Islands after the chief of which, Tahiti or Otaheite, it is usually designated. According to Ellis, it grows in the high sandy banks near the sea, or on the sides of the lower mountains. In Pereira's elements of Materia Medica the following account is given of the preparation of the fecula. "At Tahiti this is procured by washing the tubers, scraping off their outer skin and then reducing them to pulp by friction on a kind of rasp made by winding coarse twine (formed of the cocoa-nut fibre) regularly round a board. The pulp is washed with sea water through a sieve made of the fibrous web which protects the young frond of the cocoanut palm. The strained liquor is received in a wooden trough, in which the fecula is deposited and the supernatant liquor being poured off, the sediment is formed into balls, which are dried in the sun for twelve or twenty-four hours, then broken and reduced to powder, which is spread out in the sun to dry." Tacca arrow-root is a white starch like powder, having a slightly musty odour. The granules resemble somewhat those of sago-meal, but are very much smaller: when viewed sideways, they are muller-shaped, with truncate or dihedral bases, and when seen end-ways they appear circular, and occasionally angular or polyhedral. The rings are few and indistinct, and the hilum circular, sometimes fissured in a stellate manner. "Tacca arrow-root has been sold in London for some years, in packages, as arrow-root prepared by the native converts of the missionary stations in the South Sea Islands." It is sometimes spoken of as "Williams' arrow-root," after the missionary of that name. The slightly musty odour which it usually possesses show that it is not in general prepared with quite the same amount of care as is bestowed on Maranta arrow-root.

Manihot Arrow-root.—The flour or farina of Manihot utilissima, the plant which yields "tapioca," is sometimes imported into England, under the name of "Brazilian arrow-root." To the application of the word arrow-root to the fecula of this plant there exists no objection, since it resembles closely the other arrow-roots in its properties. *Manihot arrow-root* like the other kinds already described, may be distinguished by the size, and other characters of its constituent granules, which resemble somewhat closely those of Tacca arrow-root, but are considerably smaller, with a larger proportion of granules which exhibit a circular outline as seen in the field of the microscope: the hilum is usually fissured. The price of tapioca to the public varies from 6d to 10d. the pound; now, as greater time and la-

bour are expended in the manufacture of this substance than is required for the preparation of the arrow-root, the price of the latter ought to be still less than this.

Potato Arrow-root. Potato flour, or arrow-root, sometimes called British or English arrow-root, is prepared by rasping and grinding the well cleansed tubers of Solanum tuberosum into a pulp. This is repeatedly washed, and the waters strained through a sieve, which retains the cellular tissue, and allows the starch to pass through. After a time, the starch is deposited at the bottom of the vessel, is again well washed, and finally dried. Potato strach forms a white and somewhat glistening powder, which crackles like genuine Maranta arrow root when pressed between the fingers. Potato arrow-root is the cheapest of all the starches regarded as arrow-roots, the retail price varying from 4d to 6d per pound. Although a cheap and useful article of diet, it is of course inferior to Maranta arrow-root.

Arum arrow-root is procured from the tubers of Arum maculatum, the common "cuckoo pint," "wake robin" and "lords and ladies." It is prepared chiefly in Portland island; hence it is generally called "Portland arrow-root." The mode of its preparation is very similar to that adopted with the other arrow-roots: the tubers are pounded in a mortar the pulp repeatedly washed, and the water subsequently strained. As the tubers are very acrid, great care is required in the washing and straining of this arrow root, so that the acidity may be completely removed. The starch granules of arum arrow-root, are very small, and, except in size, they resemble very closely those of Tacca arrow-root; but this difference is sufficiently constant and considerable to ensure the ready identification of the two kinds. The adulteration, by mixing together Arrow-roots of different qualities and prices in various proportions most frequently consists in the addition of potato flour or arrow-root to Maranta arrow-root, the proportion being subject to every variation, the potato-flour in many cases forming the largest portion of the article. In some cases Manihot or tapioca starch or arrow-root is added to Maranta Arrow-root; and in other instances, again, this as well as potato-flour are employed together. The fraud of the substitution of an inferior for a superior Arrow-root, is most commonly practised by the substitution of potato-flour for Maranta arrow-root. In some few cases, Tapioca or Brazilian arrow-root has been substituted for Maranta arrow-root, and in others both it and potato flour have been used. The adulteration of arrow-root is also in all by the addition to a genuine Arrow-root of other but inferior starches, not usually recognised as Arrow-root. The starch usually had recourse to in this adulteration of arrow-roots is sago starch or meal, indeed, indeed, indeed

ing veins, and whose flowers are constructed with an inferior ovary surmounted by a 3-leaved calyculus; very irregular flowers, white, red, or yellow; and a single stamen, whose anther has but one lobe. With the exception of the genus *Calathea*, and of *Canna*, which is commonly cultivated under the name of Indian Shot, because of its beautiful flowers, the species included in this order are of small size, and by no means attractive, but the fleshy tubers of some of them abound in starchy matter, which renders them nutritious. Arrow-root of the finest quality is obtained from *Maranta arundinacea*, and a similar product is yielded by *Canna edulis* and others. The order is known from *Zingiberaceæ* by the anther having but one lobe instead of two. All the species are found wild in tropical countries only. The species are natives of the tropics of America Africa, and Asia. Amylaceous qualities prevail in this order, and starch is prepared from many of the species. The fleshy corms of some species of the *Canna* are eaten in Peru, and a sort of arrow-root, called Tous le Mois, is extracted from some of the species. The seeds of others, called Indian shot, have been used as a substitute for coffee, and yield a purple dye. (Lindley, *Vegetable Kingdom.*)—*Eng. Cyc.* Of these plants, though little known for their herbaceous parts containing any useful quantity of fibre, one of the South American genera has been named Calathea, in consequence of its leaves being employed in basket-making. In India, the stems of *Moocta patee* of the Bengalees, *Maranta* (*Phrynium*, Roxb.) *dichotoma* of botanists, which are straight and tapering, about as thick as a man's thumb, and from three to five or six feet high, of a beautiful, highly polished, green colour, are said to be employed in making some of the mats for which Calcutta is famous. Mr. Colebrook says: "Mats made of the split stems of this plant being smooth and particularly cool and refreshing, are termed in Hindoo *Sital-pati*, which signifies a cool mat; whence the plant itself is said to bear the name. Suspecting, however, this to be a misappropriation of the term, I have inquired of natives of the eastern parts of Bengal, who assure me that the plant is named *mucta-pata* or *patti-pata*, and the mat only is called 'sital-pati.'" The split stems, as prepared for making mats, are about four feet in length, one twentieth of an inch in breadth, thin as paper, greyish coloured, compact and shining almost like cane on the outside; finely striated on the inside, and apparently made up by the agglutination of very fine fibres. They seem admirably adapted for platting of all kinds. Many of these plants, no doubt, contain a sufficient quantity of fibre to be usefully extracted for the paper-maker. The same may be said of the innumerable plants of Ginger, Turmeric, Cardamom, and others of the nearly allied family of Zingiberaceæ, which are similarly cultivated entirely for their roots and seeds, and the herbaceous plants thrown away. These from their nature cannot but abound in useful fibre, applicable to the purpose of the paper-maker.—*Royle Fib. Pl. p.* 60.

(5212) MARA-VERIE, the Tamil name of a Ceylon tree which is much the same as the Vell-verie in size and quality. It is used for natives' huts, &c. but is not of much value.—*Edye. Ceylon.*

(5213) MARBLE.

Marmer, Dut.	Marmor, Lat.
Marbre, Fr.	Sung-i-Murmur, Pers.
Marmor, Ger.	Marmor, Rus.
Murmur, Guz. Hind.	Marmol, Sp.
Marmo, It.	

The granular limestone, or carbonate of lime of mineralogists. It is hard, compact, of a fine texture, and readily takes a fine polish. The colours by which marbles are distinguised are almost innumerable; some are quite black, others again are of a snowy white; some are greenish; others grayish, reddish, blueish, yellowish, &c.; while some are variegated and spotted with many different colours and shades of colours. Marble is found in many, if not most, primitive countries; it sometimes forms entire mountains, but more often occurs in beds. The finest solid marbles are those of Italy, Blackenburg, France, and Flanders. A strict definition of this term is perhaps impracticable, unless, with Da Costa, we limit it to th calcareous rocks "of very lively colours, and of a constitution so fine that they will readily take a good polish." In a vague sense other ornamental stones, as granite and porphyry, may be ranked among marbles, but the catalogue of the typical or calcareous marbles is long enough without these somewhat inconvenient additions. A limestone which will admit of being worked easily and equally in all directions is properly called 'freestone,' as the Bath or Ketton freestone; a rock of similar chemical composition, generally capable of being worked equally in all directions, and also of taking a good polish, deserves the title of marble; when it is granular and of a white colour, it may be useful in statuary. Da Costa, in his 'Natural History of Fossils' gives a large catalogue of marbles, disposed in methodical order, which we shall follow in the subsequent brief notices of this extensive subject.

Division 1. Marbles of one plain Colour.

Section 1. Black Marbles. Most of these contain bitumen, and are fetid when bruised.

Examples. The Namur marble, the marble of Ashford in Derbyshire, Dent in Yorkshire, near Crickhowell, Tenby, Kilkenny, &c. The marble, anciently called Marmor Lucullæum, and now Nero Antico.

Section 2. White Marbles.

Examples. The marble of Paros, in which the Laocoon and Antinous are executed; the

Carrara marble, of finer grain, much used in modern sculpture; the skye marble, noticed by Dr. M'Culloch; that of Inverary, Assynt, Blair Athol, &c.

Section 3. Ash and Gray Marbles.

Examples. A beautiful marble, of compact oolitic texture at Orelton, near the Clee Hills in Shropshire, deserves mention.

Section 4. Brown and Red Marbles.

Examples. The Rosso Antico; a rival, to which, at least in colour, has been found on the estate of the Duke of Devonshire, near Buxton. The mottled brown marble of Beetham Fell, near Milnthorp, is of good quality.

Section 5. Yellow Marbles.

Example. The Giallo Antico. Siena marble also dug at Mafra, near Lisbon. That used in ancient Rome is said to be from Numidia.

Section 6. Blue Marbles.

Example. Near St. Pons, in Languedoc.

Section 7. Green Marbles.

Example. The Marmor Lacedæmonicum of Pliny. It is dug near Verona.

Division II. Marbles of two Colours.

Section 1. Black Marbles variegated with other colours.

Example. Near Ashburton in Devonshire, Torbay in the same county, Bianco e Nero Antico, the Africa Breccia of the ancients, Giallo e Nero Antico.

Section 2. White Marbles variegated with other colours.

Example. Marble exported from Italy. Marbles of this general character occur in Siberia, at Plymouth, at Killarney, in Sweden, &c.

Section 3. Ash and Gray Marbles variegated with other colours.

These are very numerous, and occur in various parts of Europe.

Section 4. Brown and Red Marbles variegated with other colours.

Section 5. Yellow Marbles variegated with other colours.

Section 6. Green Marbles variegated with other colours.

Example. Egyptian Marbles—the Marmor Tiberium and Augustum of Pliny; some Verde Antico, as that dug near Susa in Piedmont, the beautiful marble of Anglesey (called Mona marble), the marble of Kolmerden in Sweden.

Division III. Marble with many Colours.

Example. Some of the Plymouth marble, the beautiful Brocatello or Brocade marble of Italy and Spain.

Division IV. Marbles containing Shells, Corals, and other extraneous bodies.

The Marble slabs, of China are about a foot square, and are exported to India, Sydney, South America, &c. for pavement or floors. It is a blue clouded marble, obtained to the northwest of Canton: there is also a red breccia marble brought to Canton, which is employed in tables, stone stools,

&c it is seldom sent abroad. The exportation of these slabs was formerly prohibited, and the trade henceforth is likely to increase somewhat. Ten slabs are estimated to weigh a pecul. Tiles of various sorts have in some persons been largely exported. The large square tile is about the same size, and is used for the same purposes, as the marble slabs. The tiles used by the Chinese in roofing are of two sorts, an upper and a lower piece; these are not so often sent abroad. Comp. *Dek.* The Marbles of the Madras Presidency deserve prominent notice on account of their rare color, and fine quality. The specimens sent to the British Exhibition were favorably reported upon as indicative of a valuable material, well adapted to sculptural and ornamental purposes. At present the Indian manufacture in this article is comparatively insignificant and chiefly confined to small miscellaneous articles for domestic use. It may be well worth the consideration of persons of capital and taste to endeavour to further develop the resources of this Presidency as regards this beautiful stone, and to improve the practical means of obtaining it in greater size and perfection. Marble tables, pedestals, vases, baths, and fountains are particularly refreshing, and suitable to an oriental climate and possessing as this Presidency does such an abundance of the raw material, and where labour is comparatively cheap, it seems an anomaly that so much should be imported from foreign countries at a great cost, and of a quantity not superior to some of the marble found in India. (See Report upon the Marbles of Southern India by Edward Balfour, Esq., and the interesting and valuable collection of sculptures in marble from Amrawattee in Guntoor.) The last year the purest white statuary marble and alabaster were discovered in great quantities between Nagpore and Jubbulpore; and it is reported that very large slabs can be easily quarried there at a moderate price. The Rev. S. Hislop writes to say "that the cost of slabs of granular white marble from Korhadi 3 feet by 2 and 9 inches thick is Company's Rs. 2. As soon as the navigation of the Godavery is opened up, this marble and the sandstone and coal of the same locality with the alabaster, gypsum and dolomite of Jubbulpore, will probably become articles of export. At Tinnevelly also, there is an excellent description of white marble, but considered rather too hard for statuary purposes, and Guntoor and the Ceded Districts abound with marbles of great variety of colors being tints of grey yellow and red. *A Cup and Butter Pot of Bellary marble*, exhibited by Lady Montgomery, at the Madras Exhibition of 1855, attracted deserved attention, and some *Egg Cups*, and other small domestic articles exhibited by Captain Applegath were equally worthy of commendation. The natives of Bellary have improved in this useful branch of art, and the above articles are handsome specimens of

taste, and industrial execution. The butter pots cost eight or nine, and the egg cups, two Rupees each. This is rather dear, and a drawback to their general use.—*M. E. J. R.*

(5214) MARGOSA, the Portuguese name, and Vembu the Tamil and Malayala names of a tree which grows from eighteen inches to three and a half feet in diameter. In appearance it is much like mahogany, and is used by the natives for general purposes. It produces a fruit from which an oil is extracted which is used medicinally.—*Edye Ceylon.*

(5215) MARGOSA BARK.

Nim, BENG.	Nimba, SANS.
Bewa, CAN.	Vaypum puttay, TAM.
Tel-kohumba, CYNG.	Vaympa puttay, TEL.
Nim-ka-chall, HIND.	

The bark of the *Nim* tree is bitter, and not unpleasant to the taste, and is considered by native practitioners a valuable tonic. This bark has been tried by European physicians with a success nearly equivalent to what might have been expected from the cinchona bark. The *Nim* tree is common in gardens in Bombay, and the bark is procurable in most bazars.—*Faulkner.*

(5216) MARGOSA OR NEEM OIL AZADERACHTA INDICA; AND MELIA AZADIRACH.

Vaypum Yennai, TAM.	Neem ka Tael, HIND.
Vapa noona, TEL.	

This valuable and much used medicinal oil is obtained by either expression or boiling, from the seeds of the abovementioned trees, which are common throughout the Presidency. The fruit of the *Nim* tree, is not unlike a small French olive in size and appearance. It enters much into the practice of native Physicians. The oil is very bitter, and is much esteemed by native doctors as a warm medicine, as an external application in foul ulcers, and as a liniment in rheumatic and spasmodic affections, &c. The oil is of a deep yellow colour, has a strong smell and an unpleasant bitter taste. In the year 1847-48 galls. 1,587 were exported, and in the year 1851-52, galls. 1, 917, in 1852-53, galls. 3-111. The chief market is Ceylon, but the demand is not constant. It is frequently burnt in lamps, and is sold in the bazar, under the name of "bitter oil."—*M. E. J. R.* It is cheap and easily procurable in Ceylon. Dr. Maxwell, garrison surgeon of Trichinopoly, states that he has found this oil equally efficacious to cod-liver oil in cases of consumption and scrofula. He began with half-ounce doses, morning and evening, which were gradually reduced.—*Simmonds' Comml. Product, p.* 587.

(5217) MARJORAM, SWEET.

Mir-zun-joosh, ARAB.	Murwa, GUZ. HIND.
Marjolaine, FR.	Marroo. TAM.
Majoram, GER.	

Sweet marjoram is a native of Portugal, and Palestine, but is cultivated in most parts of lower India, and may be frequently met with in gardens. The flowers are considered by Hindoo doctors as possessing cephalic qualities, and the plant is known to possess tonic virtues. It is now chiefly used in Europe as a culinary herb.—*Faulkner.* Marjoram, is very easily reared, in beds or pots, either by slips from the roots, or seed. It is used for flavoring ragouts, sauces, &c.—*Jaffrey.*

(5218) MARIGOLD, TAGETES PATULA AND ERECTA. Any of the species will do well on the plains, they require to be sown thinly in boxes or pots during the rains, when two or three inches high, they should be transplanted into the flower beds, called French and African Marigolds.—*Jaffrey.*

(5219) MARINE GLUE, patented by Mr. Jeffery in 1842, possesses very powerful cementing properties. It is formed by dissolving 7 lb. of caoutchouc in small pieces, in 4 gallons of coal naptha with frequent stirring, the solution occupying 10 or 12 days: 2 parts shell lac are then fused in an iron vessel, and 1 part of the solution being stirred well in, the glue is poured out on slabs to cool. When two pieces of wood or glued or cemented by its means, the joint becomes stronger than the fibres of the wood itself. Large masts being formed of pieces cemented or jointed together, it has been proposed to Mr. Jeffery to employ his marine glue for this purpose; but, from a Report made to the Admiralty by a board of Dock-yard Officers, in 1843, it appears that this glue is even too good for the purpose; if any part of a mast decays, it is customary to take the mast to pieces, and re-employ all the sound pieces, but it was found that a mast which had been formed by aid of the marine glue was with such difficulty separated, that the pieces were scarcely available again. The marine glue also constitutes an excellent substance for pitching or paying the seams of ships An inferior but strong marine glue is formed by simply dissolving shell-lac in naphtha. —*Tomlinson.*

(5220) MARKING NUT, MALACCA BEAN.

Beladur, ARAB.	Bhallataka Arushkara, SANS.
Gheru, CAN.	Shayng Cooty, Shayrang coitay. TAM.
Bellawane, Bhela, DUK.	Nellajiedie, Jeedighenzalo, TEL.
Bellama, GUZ.	
Bellama, Bheela, HIND.	

The tree bearing this nut (*Semecarpus Anacardium*), is a native of all the mountainous parts of India. The nuts are black, smooth, shining, and flattened on both sides. The acrid black-juice of the nut is employed by the natives externally to remove rheumatic pains, aches, and sprains, by rubbing a little over the affected part. It is also universally used for marking cotton cloth, whence its name of marking nut, the colour being improved, and prevented from running, by being mixed with lime water.

(5221) MARKING NUT OIL. SEMECARPUS ANACARDIUM.

Shayng Cottay Yennai, TAM. | Bhallahwan ka tael, HIND.
Nellajiede Noona, TEL.

The acrid and vesicating oil which is found between the two laminæ of the pericarp of the marking nut is collected and used, as a preventive against the attacks of white ants, and by native practitioners in Rheumatic and Leprous affections. By boiling the whole nut, not divested of its pericarp, an oil is also obtained which acts as a blister. The qualities of the oil of the kernel of the nut, of which a good specimen is shown by Lieut. Hawkes, require investigation. The preparation or collection either of the oil or acrid juice is liable to cause much irritation and inflammation of the hands, face, &c. of those engaged in the work. Specimens of the acrid juice (improperly called oil) were shown by the Tanjore and Goa Local Committees, Madras Tariff and Major Miller.—*M. E. J. R.*

(5222) MARMALA WATER. A fragrant perfume distilled in Ceylon from the flowers of the Ægle marmalos, and used in the ceremonial sprinkling of visitors.

(5223) MARMALADE. A confection generally made of oranges, citrons, &c., cut into very thin slices, and boiled with sugar.

(5224) MAROR PHULL, HELICTERES ISORA SCREW-TREE. This small tree grows at Ajmeer: the twisted pods are used: considered refrigerant and astringent, taken in curds in diarrhæa; one pice's size is the dose.—*Genl. Med. Top. page* 146.

(5225) MARSDENIA TENACISSIMA, MARSDENIA ROYLEI. Asclepias tenacissma.

Tongoose, ENG.
Tungoos, HIND.
Jetee Fibre,
Rajmahl Bowstring Creeper,
Asclepias, now Marsdenia tenacissima.
Asclepiadeæ.
Tungoos, TAM.
Simmonds. Mason.

This comparatively small climbing plant, with greenish yellow flowers, was found by Dr. Roxburgh's son growing in dry and barren places in the Rajmahl Hills; since then also near Chittagong. Of the fibres of the bark of this plant, the Rajmahl mountaineers make their bowstrings. These are said to last for five years, though in constant use and exposed to all sorts of weather. A drawing and full description of this plant is given by Dr. Roxburgh in his 'Coromandel Plants,' iii, t. 240. In preparing the fibres of this plant, the Hill people do not put the stems in water, but let them stand in the sun for a day till drier; from the ends, when cut, there exudes a milky juice, which thickens into an elastic substance, like, indeed forming one kind of, caoutchouc, acting in the same way in removing black lead marks. According to Dr. Roxburgh, the fibres of this plant are not only beautiful in appearance and durable, but the strongest of any he had met with. Some twine made with it bearing 248 and 343 lb. in the dry and wetted states, when Hemp twine bore only 158 and 190 lb, in the same state. Mr. W. C. Taylor since then met with the same plant near the Palamow coal-mines, having observed his boatmen twisting a substance into thread, which they called *chittee*, of which they made nets, finding it much stronger and more durable then Hemp, and not so liable to rot by being kept in water. Mr. Taylor mentions that the stems are cut into lengths, and then cut down the middle; then dried, and afterwards steeped in water for about an hour or more which enables the bark to be separated with greater ease; when the fine silky filments are separated. A 1½-inch rope having been made and sent to Calcutta, was there tested in the Master-Attendant's Office, and found to break with 903 lb., when even Europe rope broke with 1293 lb., and others with greater weights. Its elasticity was considerable, as it stood ninth in strength, but second in elasticity. It was supposed that this might possibly be caused by its being laid up by hand; and it was also observed that the result might have been better, if the yarns had been more easily (evenly)? laid up." But the plant is suited for better purposes than rope-making besides not being eligible for this purpose, from its comparative rarity and mode of preparation. Mr. Taylor states it might be easily cultivated. (*v.* 'Journ. Agri-Hortic. Soc.,' 1844, p. 22.) Specimens of the fibre of another species of *Marsdenia*, which has by Dr. Wight been named *M. Roylei*, are stated in the Catalogues to have been sent from Nepal to the Exhibition of 1851. Though the specimens have not been found, we may infer that the fibres of this species are made use of in Nepal.—*Royle Fil. Pl. p.* 304.

(5226) MARSDENIA TINCTORIA, ASCLEPIAS TINCTORIA BLUE DYE. The Karens, and sometimes the Burmese, plant a creeper that is indigenous in some sections, and which makes quite a good indigo blue, though not equal to the Ruellia dye.—*Mason.* The Javanese, who of all the Malayan race, have certainly made the highest progress in all the useful arts, have a specific term for dyeing or tinting,—"madal;" but the Malays express it only by the word for dipping, "*chalup.*" Yet the only generic words which either of them possesses for "colour," are the Sanscrit, warna; and the Portuguese, tinta. Their colours are usually sombre,—little varied, but generally fast. Blues are always produced from indigo, yielded for the most part by the Indigofera tinctoria, as in other parts of India, but in Sumatra, occasionally, from this plant the Marsdenia tinctoria, a plant of the natural order of the Asclepiadeæ. Yellows are produced from the woods of two species of Artocarpus, the jack

and champadah, and from turmeric; and reds from the bark of the root of the "*mangkudu*," the Morinda umbellata,—from the "*kusumba-jaiva*," safflower or Carthamus tinctorius, from the "*kusumba-kling*," which is the annatto, or Bixa orellana, from the sapang, or sapan-wood, Cæsalpinia sappan, and from the nidus of the lac insect. Black is produced from the rinds of the mangostin fruit, and of the "*Katapang*," Terminalia catappa, with sulphate of iron. Sails and nets are dyed, and perhaps also tanned with a wood called in Sumatra "*ubar*" which is the Ricinus tanarius of botanists. The mordants used are rice-bran, alkalis from the combustion of some vegetable matters, as the fruit stalks and mid-ribs of the cocoanut palm and alum brought from China.—*Crawfurd.*

(5227) MARSH DATE OR GROUND RATTAN, CALAMUS ROTANG: its leaves are used at Cuddalore for making ropes and mats.

(5228) MARSH MALLOW. ALTHÆA OFFICINALIS.

(5229) MARSH MALLOW, SYRUP OF: This is a mucilaginous demulcent, and for the same purposes may be prepared Syrup of Bombax malabaricum root,—of dried Abelmoschus esculentus capsules, (okra,)—of Asparagus sarmentosus, (soota moolli,)—of Bilva fruit, (bel.) Ægle marmalos. These syrups all spoil very readily. —*Beng. Phar. p.* 407.

(5230) MARSILEA QUADRIFOLIA. Lin.

Awrei keeray, TAM.	Ara koora, TEL.
Chuppati ke banjee, DUK.	Chittoor Dulla, SANS.

Ainslie, p. 252.

(5231) MARTYNIA. PEDALIACEÆ. These are handsome plants, common in India, the leaves are covered with a glutinous soft substance, the flowers are red, and pale purple, the capsule of the seeds is hard, with a hooked bill at the end. The plant thrives luxuriantly in any light rich soil.

(5232) MARTYNIA DIANDRA. An herbaceous plant with large cordate leaves, covered with a glutinous dew like substance; flowers diandrous, much like those of the sesamum. Capsule, with a curious double hooked bill.—*Ridd.*

(5233) MASK FLOWER. ALONSOA.

(5234) MASLIN. A mixture of rye and wheat. It is extensivsly grown in Durham, where bread made of this compound is in general use.

(5235) MASSALA, garm, or warm spices, includes pepper; cloves, cardamoms; cummin and cubebs:—the thunda or cold spices, comprize chillies, onions, garlic, ginger; turmeric; coriander and cummin seed, tamarand, &c.

(5236) MASSICOT. An oxide of lead, prepared from the dross of the melted metal. It is of a pale yellow colour, and is used as a pigment. —*Waterston. Faulkner.*

(5237) MASTIC, (GUM), Turkish Olibanum.

Arah, Auluk Bagdadie, ARAB.	Mastico, IT.
Mastik, DUT.	Kinneh, PERS.
Mastic, FR.	Almacegu, PORT.
Mastix, GER.	Almaciga, SP.
Roomie Mustakie, GUZ. & HIND.	Roomie mustakie, TAM.
	Sakes, TURK.

This resinous substance is the produce of the *Pistacia Lentiscus*, a native of the Levant, and particularly abundant in the island of Chios, whence it is brought to India by way of the Red Sea. The best is in the form of dry, brittle, yellowish, transparent, tears; it is nearly inodorous, and almost insipid to the taste. It forms the basis of several drying varnishes, is one of the ingredients used in fumigations, and is considered to be efficacious in promoting a healthy state of the mouth when chewed.—*Faulkner.*

(5238) MASTODON, the name of an extinct genus of gigantic Pachydermatous Proboscidian Mammals (*Mastotherium*, Fischer), whose remains are found abundantly in the third and fourth, or Pliocene, divisions of the tertiary fresh-water deposits, and also, but less frequently, in the deposits of the second, or Miocene, period. In the greater portion of their organisation the Mastodons must have closely resembled the elephants. [ELEPHANTIDÆ.] The tusks, the proboscis, the general conformation of the body and the limbs were very similar; and the principal distinction between the two genera was formed by the molar teeth. These indeed were gradually pushed forward from behind as they are in the Elephant, and displayed the same relative increase in proportion as the animal was advanced in life; but, unlike those of the Elephant, their crowns exhibited on cutting the gum large conical points of a mammiform structure, whence the animal derives its name. As these conical points were worn down by mastication, the tooth presented discs more or less large, according to the degree of attrition which it had undergone. Remains of the Mastodon were found by Captain Cautley in the Sewalik Mountains; and in assigning an age to the formation, the Captain adopts the views of Dr. Falconer, who considers the deposit to be synchronous with that from which Mr. Crawfurd obtained the remains near Prome, on the banks of the Irawaddi. Captain Cautley having found jaws in which the front teeth are not to be distinguished from the teeth of *M. latidens*, and those in the rear from the teeth of *M. elephantoides*, he conceives that the distinction which was established on detached teeth will be found to be erroneous.—*Eng. Cyc.*

(5239) MATS.

Matten DUT.	Boorya, PERS.
Nattes, FR.	Esteiras, PORT.
Matten, GER.	Progoshki, RUS.
Chuttæ, GUZ. HIND.	Esteras, SP.
Stuoje, Stoje, IT.	

A texture formed of rushes or the bark of trees, and leaves of different species of palm trees interwoven. Mats are made in various countries but chiefly in Russia, where a kind termed *bast mats* are largely manufactured from the inner bark of the lime tree. China mats are in general use in India for covering floors, and lining staircases.

Lime or Linden Tree (*Tilia europæa*), *and Russia Mats.*—The Lime tree abounds in the forests of Europe, but especially in those of Russia; and is esteemed for its sweet-scented flowers. The wood of the tree is white and light, and employed for making furniture, for turning, and for carved works. The bark of these trees when steeped in water soon separates into thin layers, which are employed for making a coarse kind of rope, for making matted shoes much worn by the Russian peasantry, and also for making the mats which are so largely exported from Russia, and which are so extensively used in England for packing furniture, as well as for gardening purposes, and for covering the floor. A Linden shoot growing in moist situations, is stated by Mr. Tooke as not fit for peeling, for the purpose of being platted into shoes, in less time than three years. To every pair of shoes, from two to four young Linden stems are requisite; and though these grow faster as they are cut, yet the consumption is enormous, and the destruction of the Linden tree is in consequence immense. For the better, larger kind of mats, trees of from eight to sixteen years are cut down when full of sap, and the bark is immediately separated both from the tree and the branches. It is first cut longitudinally, then raised with an instrument made of bone, and then torn off with the hand. When the bark has been removed, it is stretched on the ground to dry, two or three strips being laid one over the other, and kept straight by being tied down to long poles. They are employed for making ropes in some parts of England, and for well-ropes in France. When required for use, they are steeped in water, and the cortical layers readily separate from each other. The best of these layers are those which are in the interior, while the coarser layers are on the outside. The manufacture of mats is nearly confined to Russia and to some parts of Sweden. Trees of from six inches to one foot in diameter are selected in the woods, and in the beginning of summer the bark is stripped from the trees in lengths of from six feet to eight feet. These are afterwards steeped in water, till the bark separates freely into layers; it is then taken out and separated into ribands or strands, which are hung up in the shade—generally in the wood where the trees grew from which they were taken; and in the course of the summer they are manufactured into mats. The fishermen of Sweden make fishing nets out of the fibres of the inner bark. The trees from which the bark is taken are cut down in the summer, and, properly cut, are burnt in heaps into charcoal. The sap is drawn off, and, when evaporated, yields sugar. The honey of the flowers is much sought after by bees. The Lime tree is principally produced in the governments of Vialka, Kostroma, and those immediately contiguous; and in the months of May and June—the period when the bark is most easily detached from the stem—the villages in the governments in question are almost deserted, the whole population being then in the woods employed in stripping the trees. The academician Koppen, who has carefully investigated this curious subject, estimates the average annual production of mats in European Russia, as follows:

Government of	Vialka...	6,000,000 pieces
„	Kostroma...	4,000,000 „
„	Kasan...	1,000,000 „
„	Nijni Novgorod ...	1,000,000 „
„	Vologda, Tamboff. Simbrisk, and Penza...	2,000,000 „
Total	... ...	14,000,000 „

Koppen further estimates that about a fourth part of this vast quantity, or 3½ millions, are exported, the rest being consumed at home. Archangel is the principal port for the shipment of mats, and it appears that on an average of the years 1851 and 1852, the export of mats from that port amounted to 615,360 pieces a year. Large quantities are also shipped from Petersburgh, Riga, and other ports. (M'Culloch's 'Com. Dict.') The extent of the Imports of Russia Mats into Great Britain may be judged of by the following statement furnished to Dr. Royle by Messrs. Wrench:

1832	.....	840,000	1847	.....	520,359
1840	.....	817,772	1848	.....	397,553
1841	.....	508,485	1849	.....	576,565
1842	.....	532,401	1850	.....	359,223
1843	.....	861.565	1851	.....	734,659
1844	.....	449,817	1852	.....	333,008
1845	.....	634,041	1853	.....	657,040
1846	.....	898,619			

The price in Jan., 1834, was £4 10*s.* per 100, the duty included; in 1848, 95*s.* to 100*s.*; and in 1849, under 80*s.* In 1850, 90*s.*; 1851, 87*s.* 6*d.*; 1852, 85*s.* to 100*s.*; and in 1853, 120*s.* per 100.—*Royle Fib. Pl. p.* 233. Large quantities of Bast are imported into England, in the form of mats, from Russia, chiefly for the use of gardeners, who use them for covering pits and frames, or protecting plants, and afterwards, when pulled to pieces, for tying up plants and vegetables. The mats are also extensively used for packing cabinet-work and furniture in general. It is calculated that about 3,500,000 mats are exported from Russia, and about 500,000 to 800,000 are annually imported into England. They are made of the bark of the Lime or Linden tree, which, when stripped off, is also made into shoes, cordage, sacks for corn, &c.—*Royle, Fib. Pl. p.* 236. Mats, about 3,500,000 mats are

annually exported from Russia, from 500,000 to 800,000 of which are imported into England. *Mats of Arracan.* There are six kinds of Bast, called in Arracan "Sha" which might successfully be fabricated into similar mats. In 1854, the price of Russian Mats was £ 7-10-0 to £ 8 per 100 wholesale and from 2*s.* to 2*s.* 6*d.* each, retail. Mats of Bengal, called *Sital Patee*, are made from the Phrynium dichotomum. Several species of *Typha*, Juncus and Saccharum, abound in the Madras Presidency, and are applied to useful purposes. Many of the mats exported from Calcutto are made from a species of papyrus, the P. Pangorei. Some of the Burmese mats are made from the split stems of a species, of Maranta, M. dichotoma, Burm: "*Then*," which grows abundantly in the forests of Burmah and the Tenasserim Provinces. The large coarse mats in universal use in Burmah, are made from the leaf of a species of screw pine Pandanus furcatus? Burm: tha-ban: known as the Lowland screw pine, in distinction to "Highland" species of Pandanus, which grows on the highlands above tide waters, from which the smaller and finer mats are fabricated.

China Mats.—Table mats are made by the Chinese very beautifully and the demand for them has increased the importation of rattans within the last few years. They are exported to all parts of the world. Table mats are put up in sets of six each of different sizes, or else are made and put up to order. Floor mats are made of a rush cultivated for the purpose; the best are called Lientan mats. They are either plain white, or plain red and white. The manufacture of matting for sails of boats and junks employs myriads of workmen; and that for floors and envelops of boxes and cases, as many more. Floor matting is put up in rolls containing 50 mats of 6 by 4 feet; such a roll is estimated to weigh a pecul. The annual exportation to the United States is upwards of 10,000 rolls of 40 yards each, at $4 a roll. It is also sent to India and south America, Sydney, &c. When matting is shipped, care should be taken that the rolls are perfectly dry, or they will mildew and become rotten. *Mats* made of rattan for table-furniture, and of grass for floors, are largely exported from China. The latter is manufactured of different widths and patterns, and though the amount annually sent to the United States and elsewhere is calculated to exceed half a million yards, it forms a very small proportion to the home consumption. Floor matting is put up in rolls containing fifty mats, or forty yards,—*Williams.* The manufacture of mats for sails of junks and boats, floors, bedding, &c., employs thousands. A sail containing nearly 400 square feet can be obtained for ten dollars. The rolls are largely exported, and still more extensively used in the country for covering packages for shipment. A stouter kind made of bamboo splinths serves as a material for huts, and many other purposes that are elsewhere attained by boards or canvas. Rattans are also worked into mats, chairs, baskets, and other articles of domestic service. Several branches of manufacture have entirely grown up or been much encouraged by the trade at Canton among which the preparation of vermilion, beating gold leaf, cutting pearl buttons, weaving and painting fancy window blinds, and the preparation of sweetmeats, are the principal.—*Williams' Middle Kingdom, Vol.* II. *page* 142.

Colored Mattings.—The manufacture of mattings from colored grass has long been carried on successfully in the Madras Presidency, and those from Cochin, Paulghat, Tinnevelly, and Wandiwash, have been in considerable demand; the two former on account of their brilliance of colors, and fine quality, and the two latter from their extreme cheapness. Several species of grass appear to be employed for mats, some being broad, flat and soft, while others are round, fine and wiry; the mats of Cochin, Paulghat and the Western Coast are of the latter description, and are more durable in consequence. The chief defect in this manufacture was that the mats have hitherto been made in long strips which required to be sewed together when a large surface of floor is to be covered. This defect was pointed out to the Local Committee of Cochin, who have contributed two large mats 12 feet × 12 (CCV 115 and 116) each woven in a single piece of good pattern and harmonious colors. The Jury considered this an important improvement in the manufacture, and recommended a 2d Class Medal to the exhibitor; and that the two large mats be purchased for addition to the collection intended for the India house. The mats from Tanjore, Tinnevelly and in the Tariff, were creditable.

Coir Matting.—Some good specimens of plain coir matting are exhibited from Malabar, and of colored red and black matting from Canara, the Jury recommended a prize of 20 Rs. to the maker of the former, Mr. Haller, and a prize of 30 Rs. to the manufacturer of the latter. A thick door mat made of Aloe fibres exhibited by the Coimbatore Local Committee, was deserving of attention, as a novel and useful manufacture, the Jury would point out that this substance is well suited to the manufacture of rugs and carpets, as it is cheap, strong and nearly white; it is exhibited in another class dyed of the most brilliant colors and manufactured into cloth, damask, and imitation horse hair cloth.

Mats made in	Palghaut	called	Manha Poo Paya.
,,	,, Needoongund	,,	Cooroo Nare Virallee.
,,	,, Palghaut	,,	Anjee Pooketty Mookeya Valle
,,	,, ,,	,,	Shooyakunden, Virallee.
,,	,, Palghaut	,,	Kella Mooka Virallee.
,,	,, ,,	,,	Ketta Mookya Virella.

Mats are made, in the Laccadive Islands, from the coaconut leaf cut out of the heart of the tree just before it unfolds. The mats are employed in the islands as sails of ships: they are of fine quality and much esteemed when exported.

The most common and most generally useful are formed of the bamboo, those made with the shining outside strips are used for matting of rooms where the rattan is not procurable. Common bamboo mats are used for lining vessels previous to receiving cargo for covering bullock carts. Rattan mats are generally preferred for rooms, Tonga mats similar to the Bengal is prepared in many parts of Southern India, the date, and palmyra leaf mats are generally used by natives for sleeping on and are very useful; the kildara (Mogali) leaf furnishes a good material for matting for packing, the Mauritius sugar bags are made from it; different grasses and rushes furnish material for common mats, the mat-makers stain the mats with red and black.—*Rohde, M.S.S.* Paulghaut mats and those from Cochin are considered the finest in Southern India. Mats of Travancore are made from the grass *Cyperus Textilis*, and another grass called Cooray.

(5240) MAT BAGS.

Cuppas, Guz. Hind.

Are formed of the leaves of the date and other palm trees, and are extensively used in Bombay and many parts of India for packing goods. They are imported into Bombay from Sonmeeanee and the Persian Gulf.

(5241) MAUT KE BAUJEE. Amarantus tristis. Lin.

Aray keeray, Tam.	Tontakoora, Tel.
Maut ke baujee, Duk.	Jillika, Sans.

Agri. Nom. Vol. II. *p.* 252.

(5242) MAUT KE BAUJEE. Amarantus Oleraceus.—Greens. There are two sorts of these common greens, cultivated in all native gardens; the leaves are eaten as spinach or put into curries.

(5243) MATE, YERBA, Paraguay Tea. The leaves of an evergreen shrubby plant (*Ilex Paraguayensis*), largely consumed, in the manner of tea, in many parts of South America, where they are the subject of extensive commerce. The manner of using it is as follows; a pinch of the leaves is put into a small cup of warm water, and the infusion is imbibed through a little tube pierced with small holes; in the lower part, which only allows the passage of the water, and keeps back the leaves. The same leaves serve for three infusions. It is drank by some with sugar or lemon-juice, and is used at all times.

(5244) MATICO, the Peruvian styptic, a powerful vegetable astringent, was first made known to the medical profession of England by Dr. Jeffreys, of Liverpool, in the *Lancet*, as far back as January 5th, 1839. A paper on its history and power was published in May, 1843, in the "Transactions of the Provincial Medical and Surgical Association," vol. 10. It is stated to be the *Piper angustifolium* of Ruiz and Parsons. Dr. Martin believes it to be a species of *Phlomis*. The leaves are covered with a fine hair.

(5245) MAUND, a measure of weight, which varies from 25 lbs. to 84, according to the substance weighed.

(5246) MAURANDIA BARCLAYANA, &c. Very pretty creepers, with pink, white and blue flowers, require a rich soil, well adapted for mixing amongst other creepers on arbors or trellises. —*Jaffrey.*

(5247) MAURANDIA. Scrophulariaceæ. Maurandia Semperflorens. These are very elegant climbing plants with dark blue and white, also purple coloured flowers, well adapted for trellis work, and are easily grown from seed, the plants thrive well in a good soil, either in pots or on the ground.—*Riddell.*

(5248) MAYBYOUNG. This is a hard, tough, knotty wood, which the Tavoyers select for anchors to their large boats, wooden anchors laden with stones constituting the greater part in use. I have never seen the tree.—*Mason.*

(5249) MEADOW GRASS. Poa. In Tenasserim, Meadow grass has one or two representatives among the most conspicuous grasses.—*Mason.*

(5250) MEADOW SAFFRON, Colchicum.

Sorinjan, Arab.

Is a bulbous plant (*Colchicum autuminale*), the roots and seeds of which are employed in medicine.—*Faulkner.*

(5251) MEAL.

Meel, Dut.	Farine, It.
Farine, Fr.	Farina, Lat.
Mehl, Ger.	Muka, Rus.
Atta, Guz. & Hind.	Farina, Sp.

The edible parts of wheat, oats, rye, barley, and pulse of different kinds, ground into a coarse flour.—*Faulkner.*

(5252) MECONOPSIS, (from μήκων, a poppy, and ὄψις, a resemblance), a genus of Plants belonging to the natural order *Papaveraceæ*, and formerly referred to *Ppaver*. This genus stands between *Papaver* and *Argemone*. It has 4 petals, numerous stamens, a short style, 5-6-radiating free stigmas, the capsule obovate, opening by pores beneath the apex.—*Eng. Cyc.*

(5253) MECONOPSIS ACULEATA. A native of Nepal, Choor, Kedarkanta, Peer Punjal. The roots are reputed to be exceedingly narcotic. A fine drawing of this plant is published in Royle's Illustrations of the Botany of the Himalayas. An alcoholic extract of one drachm of the root given to a small dog produced no perceptible effect.—*O'Shaughnessy, page* 184.

(5254) MECONOPSIS NEPALENSIS, a Nepaul plant, is described as being extremely poisonous, especially its roots.—*Eng. Cyc.*

(5255) MEDICINAL SUBSTANCES. The medicinal substances employed by the people of Eastern and Southern Asia, are very numerous.

Dr. Impey mentions that drugs to the number of ninety are found perfect substitutes for those employed in Europe. The following are the better known.

Catechu,	Acacia catechu.
Aconite,	Aconitum ferox.
Sweet flag,	Acorus calamus.
Bael fruit,	Aegle marmelos.
Mutty pal,	Ailanthus malabaricus.
Aloes,	Aloes indica.
Galanga root,	Alpinia galanga.
Lemon Grass, or Citronelle,	Andropogon citratum.
Roosa Grass,	„ calamus aromaticus.
Prickly poppy,	Argemone Mexicana.
Indian Birthwort,	Aristolochia indica.
Dhak kino,	Butea frondosa.
Indian hemp,	Cannabis sativa.
Senna leaves,	Cassia senna.
Purging Cassia,	Cathartocarpus fistula.
	Chiretta.
Clitorea,	Clitorea ternatea.
	Cocculus Indicus.
	Colchicum.
Croton seed,	Croton tiglium.
Colocynth,	Cucumis colocynthis.
Thorn apple,	Datura stramonium.
Foxglove,	Digitalis purpurea.
Borneo Camphor,	Dryobalanops camphora.
Gamboge,	Garcinia pictoria.
Dikkamully gum,	Gardenia lucida.
Bonduc nut,	Guilandina bonduc.
Chaulmoogra,	Gynocardia odorata.
Country Sarsaparilla,	Hemidesmus indicus.
Hydrocotyle,	Hydrocotyle asiatica.
Henbane,	Hyoscyamus niger.
	Juniper Berries.
	Kreyat.
Linseed,	Linum usitatissimum.
Chiretta, variety of,	Ophelia elegans.
Assafœtida,	Narthex assafœtida.
Opium,	Papaver somniferum.
Cubebs,	Piper cubeba.
Black pepper,	Piper nigrum.
Indian Leadwort,	Plumbago zeylanica.
True kino,	Pterocarpus marsupium.
Pomegranate Rind,	
Rhubarb,	Himalayas and Tibet.
Castor Oil,	Ricinus Communis.
Different sorts of Galls,	Terminalia catappa, and other species.
Country Ipecacuanha,	Tylophora asthmatica.
Sarsaparilla,	Smilax.
Nux vomica,	Strychnos nux vomica.
Clearing nut	Strychnos potatorum.
Connessee bark,	Wrightia antidysenterica.

M. E of 1857.

The Tenasserim Provinces are rich in medicinal plants, both in number and quality. Lindley's Flora Medica contains descriptions of all the known medicinal plants in the world, and more than a tithe of the whole number may be seen growing on the Tenasserim coast. Were we deprived of European drugs, and left to our own resources; we could find good substitutes for almost every article in the Medical Flora. Besides those to which separate paragraphs have been allotted, the bark root of the red cotton tree, and the roots of the clitoria are emetic; and the root of *Tylophora vomitoria* has been pronounced by Indian practitioners not inferior to ipecacuanha for any of the purposes to which that medicine is applied. *Cassia fistula* pods, the chebula fruit, the root of the heart seed, the seeds of the Sapodilla, Otaheite gooseberry, and physic nut are aperient or purgative. The gum of the white cotton tree, the bark of *Wrightia antidysenterica*, and the peel of the mangosteen are prescribed in bowel complaints. The green fruit of the papaya, the root of the Persian lilac, and the fruit of the Rangoon creeper are vermifuges. The bitter roots of *Sida acuta*, and *Tephrosia purpurea*, and the seeds of the musk-mallow or musk plant, are deemed cordial and stomachic, and the bark of *Guilandina Bonduc*, is considered a good substitute for cinchona where that cannot be had. The decocted leaves of the goat-footed ipomœa are used as an external application in cholic. The leaves of *Vitex trifolia* are applied in diseases of the spleen. The bark of the white plumbago root will raise a blister, it is said, almost as quickly as cantharides. The oil of the cashew nut "has been used successfully in ring-worms, cancerous ulcers and corns." The mango tree exudes a large quantity of gum-resin resembling bdellium, and an indigenous pine can furnish any quantity of turpentine. The bark of the root, the leaves, and the fruit of the Bengal quince, are as popular with the natives, as the root, bark, flower, and fruit of the pomegranate, which have been famous for their medicinal properties ever since the days of Celsus—*Mason*.

(5255) MEDICAGO (from Μηδική, the Greek name of one of the species), a genus of Plants belonging to the natural order *Leguminosæ*, to the tribe *Loteæ*, and the sub-tribe *Trifolieæ*. It has the calyx somewhat cylindrical, 5-cleft, the keel rather removed from the vexillum; the stamens diadelphous; the legume many-seeded, of various forms, reniform, falcate, or cochleate, but usually twisted in a spiral manner. The species are herbs or shrubs, with the stipules usually cut; the leaves trifoliate, the leaflet usually toothed, and the peduncles 1-2-many flowered. They are exceedingly numerous, upwards of 80 species having been described.—*Eng. Cyc.*

(5256) MEDICAGO SATIVA, Lucerne has many flowered racemes; the pods compressed, spiral, with two or three turns, downy, unarmed; the pedicels shorter than the calyx or bract; the leaflets obovate, oblong, dentate above, emarginate. This plant is a native of Europe, and is found wild in England and Scotland. It has an erect stem, with yellow or violet flowers. It is commonly cultivated in the fields of Europe, and Babington says that "the wild specimens found are scarcely naturalised." This is the Μηδική of Theophrastus, 'Plant. de Caus.,' lib. 2, cap. 20; and the *Medica* of Pliny, lib. 2, cap. 20; and the *Medica* of Pliny, lib. 18, Cap. 20.—*Eng. Cyc.* Lucerne is cultivated in the Deccan for feeding horses, also in Goozerat, where it is coming fast into use among the na-

tives as green food for cattle. Propagated by seed; may be sown at any season, in beds or rows. It requires much water, and each plant should have five or six inches of space allowed to it. Cultivators generally cut it, as it begins to blossom, when fresh shoots spring up, and a succession of crops is continued in this way for several months, by manuring it occasionally.—*Riddell.*

(5257) MEEAN MILILE. A very hard, fine, close grained, heavy Ceylon wood.

(5258) MEERSCHAUM, a Mineral belonging to the series of Silicates of Magnesia. It is dull-white, opaque, and earthy, nearly like clay. Its hardness is 2·0, and specific gravity 2·6 to 3·4. A variety from Anatolia, analysed by Thomson, gave—

Silica,...	42 0
Magnesia, ...	30·5
Water, ...	23·0
Lime, ...	2·3
Alumina, ..., ...	2 0
	99·8

When heated it gives out water and a fetid smell, and becomes hard and perfectly white. When first dug up it has a greasy feel, like soap, and on this account is used by the Tartars in washing their linen. It is known in Europe from its being made use of in Turkey to make the bowls of tobacco-pipes, which are hence called meerschaums. These pipes are first imported into Germany, where they are softened in tallow and wax, and then polished. *Aphrodite* and *Quincite* appear to be varieties. (Dana, *Mineralogy.*)—*Eng. Cyc.*

(5259) MEETHEE. TRIGONELLA FŒNUM-GRŒCUM. Fœnugreek. This is a small annual, commonly cultivated during the cold season. The greens are used by the natives and the seed in curries. It is sown like all other common greens. —*Riddell.*

(5260) MEETHEE KUDHOO. CUCURBITA PEPO. Sweet Pumpkin. This is grown at the same time as all the other species, and if hung up in a dry place is an excellent store vegetable, keeping for several months.—*Riddell.*

(5261) MEGACHILE. The nest of the leaf-cutter bee is to be found in thousands in the cliffs of the hills of the Soane valley with May-flies, Caddis-worms, spiders, and many predaceous beetles.—*Hooker Him. Jour. Vol.* 1. *p.* 52.

(5262) MELALEUCA (from μέλας, black, and λευκός,, white), a genus of Plants belonging to the natural order *Myrtaceæ*. It has the calyx-tube nearly hemispherical, the limb 5-partite; the petals 5; the stamens numerous, combined into 5 elongated bundles, which alternate with the petals; the anthers incumbent; the style filiform, the stigma obtuse; the capsule cannate with and inclosed in the thickened tube of the calyx, which is sessile on and adnate at its base to the flower-bearing branch, 3-celled, many-seeded; the seeds angular. The species are trees or shrubs with alternate or opposite entire leaves, equal at the base, with flowers perfectly sessile, or somewhat combined with the branch, arranged in spikes or heads, and of a white, yellowish, or purplish colour.—*Eng. Cyc.*

(5263) MELALEUCA CAJUPUTI. (Roxburgh), *M. minor* (Smith), *Melaleuca Cajuputi*, Roxb. (fig. 64), forms a small tree with an erect but crooked stem covered with thick, rather soft, light-coloured bark; branches scattered, with slender twigs which droop like those of the Weeping Willow. Leaves alternate lanceolate, acute, slightly falcate, 3 to 5 nerved, while young silky, and diffusing a powerful odour when bruised. Spikes terminal and from the extreme axils, downy as well as the calyx and branchlets, while in flower there is only a scaly conic bud at the apex, which soon advances into a leafy branchlet. Bracts solitary, 3 flowered. Calyx urceolate, (fig. 64, 3,) limb 5 parted. Petals 5, white, scentless. Stamens from 30 to 40, in five bundles; filaments 3 or 4 times longer than petals. Anthers incumbent with a yellow gland at the apex. Style long. Stigma obscurely 3-lobed. Ovary ovate, and like the capsule 3-celled, (f. 64. 2 and 1,) many seeded, lower half united with, but the capsule is enclosed within the thickened tube of the calyx. Seeds angularly wedge shaped. A native of the Molucca Islands, especially of Bocrou, Manipe and of the S. of Borneo. It is called *Daun kilsjil*, but also Cajuputi. The leaves are collected on a warm dry day in autumn, and placed in dry sacks, in which they neverthless become heated and moist. They are then cut in pieces, macerated in water for a night, and then distilled. Two sackfuls of the leaves yield only about 3 drachms of the oil. This is clear and limpid, of a light green colour, very volatile, diffusing a powerful odour, having a warm aromatic taste, something resembling that of Camphor, followed by a sense of coolness. Sp. Gr. 0·914 to 0·927; soluble in Alcohol. It boils at 343°. When distilled with water, a light and colourless oil first comes over, and then a green-coloured and denser oil, which with less odour, is more acrid. Comp. C_{10} H_9 O=77. Some adulterations are occasionally practised with this oil, especially at the time when it reached a high price, chiefly with the Oils of Rosemary and of Camphor; but it is now commonly met with in a pure state, and without any admixture of Copper. In its *Action* and *Uses*, it is Diffusible Stimulant, Antispasmodic; externally in Rheumatism. Surprise was excited in India when Cayaputi Oil was stated to be a cure for Cholera, as Oil of Peppermint is as useful. Dose ℥ iij.—℥v. given on a lump of Sugar—*Royle.*

(5264) MELALEUCA LEUCODENDRON, White-Tree, or Cajeput-Tree, has alternate long lanceolate acuminated falcate 3-5-nerved leaves; the flower-bearing branches pendulous; the flowers in spikes rather distant, which, as well as the rachis, are quite glabrous. It is a native of the East India Islands, and was at one time supposed to yield the oil of commerce. Roxburgh asserts that it possesses little or no fragrance in its leaves, and that it is seldom or never used for the distillation of the oil which is used in the European markets. Upwards of 30 species of *Melaleuca* have been described, the majority of which are natives of Australia. Many of them are fine plants with beautiful blossoms, and very desirable for the conservatory or greenhouse. They grow well in a mixture of peat, loam, and sand, and may be propagated by cuttings, which will readily take root if planted in a pot of sand and placed under a hand or bell-glass. (Lindley, *Flora Medica*; Don, *Dichlamydeous Plants.*—*Eng. Cyc.*

(5265) MELANORRHÆA, a genus of Plants belonging to the natural order *Anacardiaceæ*, so called from the brown fluid with which every part of the principal species abounds turning black upon exposure to the air.—*Eng. Cyc.* In the Tenasserim Provinces, there are two indigenous species Melanorrhæa glabra and M. Usitata, of the same genus that produces the common black varnish; but Mr. Mason, is not aware that the exudation which they yield is applied to any economical purpose.—*Mason.*

(5266) MELANORRHÆA USITATA.

Theet-see, Burm.

This is the *Theet-see* or *Lignum vitæ* of Pegu. It is plentiful in the Tounghoo and Prome Forests, especially in the former. It is of dark red colour, of extreme closeness of grain and density of structure, with a specific gravity so great, that it serves in place of iron as anchors for native boats. Its great hardness and weight prevent its being employed in house-building. It would answer for sheaths or block-pulleys and other purposes connected with machinery, where great strength and density are required. The tree is very common above the parallel of Tounghoo and grows to a girth of six feet Dark-brown wood. —*McClelland. M. usitata*, which is familiarly known as the Birmese Varnish-Tree, or Theetsee, was not described by botanists until discovered by Dr. Wallich, and figured in his splendid work 'Plantæ Asiaticæ Rariores,' t. 11 and 12. The tribe to which it belongs abounds in plants yielding a blackish, acrid, and resinous juice used for varnishing and other such purposes, as the Marking Nut and the Japan Varnish-Tree. This tree was first seen near Prome, and is found in different parts of Birma and along the coast from Tenasserim to Tavoy, extending from the latter in 14° to 25° N. lat., as Dr. Wallich has identified it with the Kheu or Varnish-Tree of Munipoor, a principality in Hindustan, bordering o the north-east frontier districts of Silhet an Tippera. It grows especially at Kubbu, an e tensive valley elevated about 500 feet above th plains of Bengal, and 200 miles from the neare sea-shore. There it attains its greatest size; som and those not the largest, having clear stems 4 42 feet to the first branch, with a circumferen near the ground of 13 feet. It forms extensiv forests, and is associated with the two stap timber-trees of continental India, Teak and Sa (*Tectona grandis* and *Shorea robusta*), especiall the latter, and also with the gigantic Wood Oil Tree, a species of *Dipterocarpus*. Th Theetsee forms a large tree, with the hab of *Semicarpus*, and abounds in every part wit a viscid ferruginous juice, which quickly become black by the contact of the atmosphere. It leaves are large, coriaceous, simple, very entire and deciduous. The panicles of flowers ar axillary, oblong; those of the fruit simple an lax, with very large rufous and finally ferrug nous involucres. It sheds its leaves in Novem ber, and continues naked until the month of May during which period it produces its flowers an fruit. During the rainy season, which lasts fo five months, from the middle of May until th end of October, it is in full foliage. At Prom a considerable quantity of varnish is extracte from this tree, but very little at Martaban. I is collected by inserting a pointed joint of a bam boo, which is closed at the other end, int wounds made in the trunk and principal bough which are removed after 24 or 48 hours, an their contents, which rarely exceed a quarter o an ounce, emptied into a basket made of bambo and rattan previously varnished over. The co lecting season lasts from January to April. I its pure state it is sold at Prome at about 2*s.* 6 for about 3½ lbs. avoirdupois. (Wallich.) M Smith, who was long resident at Silhet, and wa acquainted with this substance in 1812, state that it is procurable in great quantities fro Munipoor, where it is used for paying river craft and for varnishing vessels designed t contain liquids. The drug, he says, is conveye to Silhet for sale by the merchants who com down annually with horses and other objects o trade. In Birma, Dr. Wallich states that almos every article of household furniture intended t contain either solid or liquid food is lacquere by means of it. The process consists in firs coating the article with a layer of pounded calcin ed bones, after which the varnish is laid o thinly, either in its pure state or variously co loured. The most difficult part consists in th drying. It is also much employed in the pro cess of gilding; the surface, being first beamea ed with this varnish, has then the gold leaf im mediately applied to it. Finally, the beautifu Pali writing of the Birmese on ivory, palm-leave or metal, is entirely done with this varnish in it

native and pure state. Some difference of opinion exists as to the effects of this juice on the human frame. Dr. Wallich states that it possesses very little pungency, and is entirely without smell, and that both Mr. Swinton and himself have frequently exposed their hands to it without any serious injury, and that the natives never experience any injurious consequences from handling its juice; but he has known instances where it has produced extensive erysipelatous swellings attended with pain and fever. Sir D. Brewster, on the contrary, considers it a very dangerous drug to handle, one of his servants having been twice nearly killed by it. A second species of the genus, *M. glabra*, was obtained by Dr. Wallich from Tavoy. (Wallich, 'Pl. As. Rar.,' i., p. 9, t. 11 and 12; and 'Edinb. Journ. of Science,' viii., p. 96 and 100.)—*Eng. Cyc.*

(5267) MELASTOMA (from μέλας, black, and στόμα, a mouth, because the berries when eaten stain the mouth black), a genus of Plants, the type of the natural order *Melastomaceæ*. It has the tube of the calyx ovate, half-adhering to the ovary, densely covered with scales or bristles; the limb 5- rarely 6-cleft, the segments alternating with the appendages, both deciduous; the petals 5-6; the stamens twice the number of the petals; the anthers oblong linear, a little arched, opening by a pore at the apex, each furnished with a stipe-formed connective, which is in some species elongated and in others short, but always biauriculate or emarginate in front; the free part of the ovarium conical and bristly: the style filiform, somewhat thickened at the apex; the stigma a pruinose dot; the capsule baccate, 5-6-celled, opening irregularly; the seeds cochleate. The species of this genus are shrubs, which are usually covered with strigæ. The leaves are petiolate, and either quite entire or serrulated. The flowers are large, white, rose-coloured, or purple. Between 30 and 40 species of *Melastoma* have been described. They grow in the warmer districts of the Old and New World, and are found in South America, Asia, and Africa. Their flowers are very handsome, and all the species may be cultivated for ornament. They grow well in a mixture of loam, peat, and sand, and young cuttings root freely in sand in heat under a hand-glass. (Lindley, *Vegetable Kingdom*; Don, *Dichlamydeous Plants.*)—*Eng. Cyc.*

(5268) MELASTOMACEÆ, *Melastomads*, an extensive natural order of Polypetalous Exogenous Plants nearly related to *Myrtaceæ*.—*Eng. Cyc.*

(5269) MELASTOMA MALABATHRICUM, Malabar Melastoma, is a shrubby plant with tetragonal branches rough from strigæ; the leaves elliptic-oblong, obtuse at the base, acute at the apex, quite entire, green on both surfaces, and scabrous from strigæ; the corymbs 1-5-flowered; the calyx clothed with adpressed strigose scales, with ovate acute lobes; the connectives of the anthers short, or very long. It is a native of the East Indies, and frequent in the Indian Archipelago. The leaves of this plant are employed by the natives where it grows as a remedy in diarrhœa, dysentery, and mucous discharges.—*Eng. Cyc.* In the Tenasserim Provinces, this species of melastoma with large gaudy purple petals, and long yellow stamens, is a common weed. Its calyx opens like a lid, and bears a fruit which in taste and flavour strongly resembles the blackberry of temperate regions. In Bengal the same plant is cultivated as a garden flower, but it does not compare with the wild plant of Tenasserim.—*Mason.* This is one of the Black-Dye Plant of Asia. The blossoms of the shoe-flower plant are used by the Chinese to dye leather black, the juice of the cashew-tree gives a black to linen, and the fruit of this melastoma affords a black dye—*Mason.*

(5270) MELANIA. Lamarck gives the rivers of the East Indies, Madagascar, the Mauritius, &c., as the locality of *M. amarula*, the animal of which, he says, is very bitter, and passes for an excellent remedy for the dropsy. The apex of all the species is generally eroded as the animal advances in age. Woodward, in his 'Manual,' says, there are 160 recent species. The following are sub-genera:—*Melanatria*, Bowdich; *Vibex*, Oken; *Ceriphasia*, Sw.; *Hemisinus*, Sw.; *Melafusus*, Sw.; *Melatoma*, Anthony; *Anculotus*, Say; *Amnicola*, Anthony; and *Pachystoma* Gray—*Eng. Cyc.*

(5271) MELIA (so called from Μελία, the Greek name of the Common Ash, which one species of the genus is thought to resemble in foliage), a genus of Plants belonging to the natural order *Meliaceæ*, to which it has given its name, and which is, like *Melia*, characterised by having the filaments of the anthers combined into a tube, with the anthers sessile within it, and opening inwards; the seeds without wings. The species are few in number, and chiefly Indian; one is naturalised in the south of Europe, and one is found in North America.—*Eng. Cyc.*

(5272) MELIA AZADIRACHTA. Lin.

Vaypum marum. TAM.

Flowers of the Indian azadirachta.

Vaypum poo, TAM. | Vaympa poo, TEL.
Neem ka pool, DUK. |

M. Azadirachta, the Neem-Tree or Margosa-Tree of the peninsula of India, has been separated into a distinct genus on account chiefly of its ternary, not quinary, structure of the parts of the pistil, and its single-seeded fruit. This has been named *Azadirachta* from the Persian (Azad-i-Du rukht, 'the excellent tree'). Its bark is bitter, and considered a valuable tonic. The fleshy part of the fruit (like that of the olive) yields a fixed oil, which is bitter, and considered anthelmintic and stimulant. The leaves are universally used in India for poultices, and both the flowers and seeds are irritating and stimulant. According to

Dr. Ainslie, a kind of toddy is procured by fermenting the sap of healthy young margosa-trees. The wood is serviceable, that of old trees is very beautiful and well adapted for furniture, the bark is astringent as well as the leaves, a decoction of which is used as a remedy for itch with effect, the seeds yield a bitter oil which is useful as an external application; the flowers are collected for making a kind of chatun.—*Rohde M.S.S.* In general it is a soft reddish coloured, rather loose textured wood, which however takes a pretty good polish, and is much used for cabinet-making purposes, under the name of bastard cedar.—*Wight.*

(5273) MELIA AZEDARAK, sometimes called Persian Lilac, Pride of India, and Common Bead-Tree (Hill Margosa by Dr. Ainslie), is said by Dr. Roxburgh to be a native of China; it is also a native of the north of India. It is much cultivated in the southern part of the United States of America. It is called Dek in the northern provinces of India, and may be confounded with another species under the name *Azedarach* by Avicenna. When in flower it has some resemblance to the Lilac, and its flowers are very fragrant. The berries are sweetish, and, though said to be poisonous, are eaten by children in the United States without inconvenience, but are reputed to be a powerful vermifuge. The bark of the root in its recent state has a bitter nauseous taste, yielding its virtues to boiling water, and is cathartic and emetic, and considered in the United States an efficient anthelmintic, and also useful in infantile remittents.—*Eng. Cyc.* The Melia Azedarak or Persian Lilac or Hill margosa, *Dek*, flowers in the Botanical Garden of Calcutta during the hot season; it thrives luxuriantly, and becomes a large useful timber tree, of very great beauty. Its flowers are like those of the lilac, and sweetly fragrant. (Roxb. ii p. 395.)—*O'Shaughnessy.*

(5274) MELIA BUKAYUN is distinguished by Dr. Royle from the West Indian *M. sempervirens* of Schwarz, with which it was united by Dr. Roxburgh. This tree appears to be a native of Persia, though common throughout India. It is called by the Arabs Ban, and by the Persians Azad-i-Durukht. It is probable therefore that this may be one of the trees included under the *Azedarach* of Avicenna. The seeds are bitter, and considered laxative and anthelmintic, as is also the bark. *M. tomentosa* is a species found in the Island of Penang; and *M. composita*, in which are included both *M. superba* and *M. robusta*, is a species found in Malabar and Mysore.—*Eng. Cyc.*

(5275) MELIA ROBUSTA. A large tree a Native of Malabar: in seven years the trunk of one raised in the Calcutta gardens attained a circumference of forty-four inches and a height of forty-six feet.—*Rohde M.S.S.*

(5276) MELIACEÆ, *Meliads*, a natural order of Polypetalous Exogenous Plants, distinguished from all others by their stamens being united into a complete cup, within and often below the rim of which the anthers are inserted. It consists of trees or shrubs with alternate often compound leaves, inhabiting all countries within the tropics, but very rare in colder climates; *Melia Azedarach*, or Bead-Tree, a Syrian plant, now naturalised in the south of Europe, forming the principal exception. In general the species are bitter and astringent, but they are sometimes dangerously poisonous, acting violently as emetics and purgatives. Notwithstanding this, the pulpy fruit of the *Lanseh* is esteemed in the Indian Archipelago; and that of *Milnea edulis* is eaten in Silhet where it seems to resemble the Litchi and Longan of China. There are 33 genera and 150 species.—*Eng. Cyc.*

(5277) MELIA SEMPERVIRENS or BUKAYUN. Ever-green Bread Tree.

Bukayun, Bukain, PERS. | Maha nimba, BENG.
Ban, ARAB. |

A smaller tree than the M. Azedarach—the flowers bluish.—*O'Shaughnessy, page* 243-244. It is common at Ajmeer; as is also the large deciduous variety. This is the chief tree in compounds, being very ornamental when in blossom, and odoriferous.—*Genl. Med. Top., p.* 193.

(5278) MELICOCCA TRIJUGA.

Kobin or Jobin, BURM.

A most valuable timber, called by the Burmese Kobin, and employed by the natives of the country for cart-wheels, oil-mills, and other purposes requiring great strength and solidity. It is found in greatest perfection on the banks of the Sitang in the Kareen Forests above Tounghoo; but it is also found throughout the Pegu and Tounghoo Forests in abundance, more particularly the latter. It is also found along with Teak in Tharawaddy and Prome Forests. Light-brown wood.—*McClelland.*

(5279) MELILOTUS. MELILOT. Griffith saw large fields of melilot in the neighborhood of Ava, but Mr. Mason has not seen it in these Provinces.—*Mason.*

(5280) MELILOTUS ARBOREA. BOKHARA CLOVER. A plant under this name has attracted some notice in Ireland, on account of its fibre. It is the *Melilotus arborea* and is nearly allied to *M. leucantha*, and therefore not a true Clover. It grows so freely as to yield five or six cuttings in the season of green herbage, from which, it is said, a considerable proportion of strong fibre may be obtained; but the Committee of the Irish Flax Society state, that the trials made in steeping this plant were unsuccessful with them.—*Royle, Fib. Pl. p.* 198.

(5281) MELOE. The Linnæan genus *Meloe* included the several genera of Heteromerous *Coleptera* now forming the family *Cantharidæ*, interesting on account of its including those beetles known under the name of 'blistering flies,' and employed in medicine. [CANTHARIDÆ.] The term *Meloe* is now restricted to the Apterous *Cantharidæ*, and the species are all beetles with large and swollen bodies, and short oval elytra, lapping over each other at the base of the suture. They are sluggish creatures and feed on various plants, especially the species of *Ranunculus*. When alarmed they emit from the articulations of their legs an oily, yellow, or reddish liquid. Latreille maintained that this insect was the *Buprestis* of the ancients, to which noxious qualities were attributed. (See his paper on the subject in the 12th volume of the 'Memoires du Museum d'Hist. Naturelle.') The nature of the larva of the *Meloe* has been a subject of considerable discussion among entomologists, having been supposed to be a minute, active, parasitic animal found on bees and flies. Most entomologists have held this view since the time of Linnæus, but the observations of Geoffroy, Newport, and Westwood, go far to prove that it is a mistake, and that there is no anomaly in the case.—*Eng. Cyc.*

(5282) MELOE TELINI. MYLABRIS CHICOREI. The blistering-beetle, or native blister-fly of East India, abounds at Lahore.—*Dr. Honigberger, p.* 307. Telini is the Hindoostanee name given in the higher provinces of India to an excellent substitute for the Spanish fly. It abounds in Bengal, Behar and Oude; particularly in the rainy season, during which period, Dr. Fleming tells us, it is seen feeding on the flowers of Cucurbitaceos plants. Ainslie had not met with it in lower Hindoostan.—*Ains. Mat. Med. p.* 118.

(5283) MELOE TRIANTHEMA. While the fly called Telini in higher Hindoostan is often used as a substitute for the Spanish fly, Dr. Fleming informs us that another species of Meloe, which has got the scientific appellation of Meloe Trianthema from being frequently found in fields over-run with the common plant Trianthema Decandia (Willd.) is now much used, as a safe and efficacious epispastic in the Medical Hospitals of the upper provinces. Its peculiar qualities were discovered by Dr. Adam Burt, Superintending Surgeon of the Bengal Establishment, in 1809, who first noticed the insect in fields around Muttra; it has since, however, been ascertained that it abounds in every part of the Doab, and in the districts on the right banks of the Jumna. Dr. Ainslie learned that this valuable fly had never been met with in lower India.—*Ainslie's Mat. Med. p.* 297.

(5284) MELOCHIA CORCHORIFOLIA, Lin. Hort. Mal.

Poonnacoo keera, TAM. | Ganuka peindie koora, TEL. Tjeroo, URIA.

The whole of this plant, with the exception of the root boiled in oil, is supposed, on the Malabar coast, to be an efficacious remedy for preventing bad consequences from the bite of a water snake. See Hortus Malabaricus, part 9th page 143.—*Ains. Mat. Med. p.* 134.

(5285) MELON.

Khurbooza, HIND.

Rock, green, and musk melons are all sown in the Deccan at the same time,—generally in beds of rivers where the soil is light and sandy. They are very seldom sown in gardens. The seed is put down in November, three or four together, with as rich manure as can be procured. The plants must not be close together—a distance of from six to eight feet is generally allowed. They come in about March, and continue until the rains. In Bombay they are in season at the same time, and a second crop is grown during the rains: this is not the case in the Deccan. The water melon (*Hind.* Turbooza) is also to be had at the same time, and grown in a similar manner. The seed should always be preserved from the finest and richest-flavored fruit, and is better for being three or four years old. The green melon is the finest flavored, although many of the others are very good, the melons growing finer in the sandy beds of rivers is attributed to the temperature being more equal about the roots than it is in beds in the garden—especially during the night.—*Riddell.*

(5286) MELON, MUSK. CUCUMIS MELO. A very indifferent musk melon is cultivated by the natives generally.—*Mason.*

(5287) MELON SEED OIL, CUCUMIS MELO. Pitcha Pusjhum—harbooza, Khurbooza.

(5288) MELON, WATER. CITRULLUS CUCURBITA. Both Burmese and Karens raise water melons, but they are neither so large nor so sweet as those of America.—*Mason.*

(5289) MEMECYLACEÆ, are a very small natural order of Polypetalous Exogenous Plants, consisting of a few tropical species of little interest. Most of them inhabit the East Indies, the Mauritius, and Madagascar. They are in habit and foliage like *Myrtaceæ*, with which order they agree in most respects; but they have anthers which in form resemble those of many *Melastomaceæ*, and the leaves have no transparent dots. From the latter order they are distinguished by their leaves not being ribbed, and by their cotyledons being convolute. In the opinion of Brown and Chamisso, it is rather as a section of *Melastomaceæ* than as a peculiar order, that *Memecylaceæ* are to be accounted. No useful properties have been assigned to any of the species, except to *Memecylon edule*, an East Indian plant, whose leaves, according to Rox-

burgh, are an ingredient in the dyes of Coromandel, and whose ripe astringent pulpy black berries are eaten by the natives.

(5290) MEMECYLON EDULE, Roxb. 82.

Aalee pundoo, TEL.

Aalee pundoo is the Teloogoo name of a berry which grows upon a small bush, common in most jungles on the Coromandal coast, it has much pulp of a bluish color, and is of an astringent quality.—*Ainslie, p.* 221.

(5291) MEMECYLON TINCTORIUM. Aliakoo or Casau elay.

Kasha marum, TAM. | Alaika chettoo, TEL.

This tree is said by Rheede to abound in the woods about Cochin. Its leaves are known to be used as a dye stuff.—*M. O. C.* It is a small tree common in jungles in the Carnatic. The wood is brought into Madras for firewood and a large quantity of the leaves are imported daily for dyeing purposes. Cold infusion of the leaves imparts a yellow dye.—*M. E. J. R.* In Tenasserim, this small blue flowered species of memecylon bears its flowers in compound corymbs, which contrast favourably with its shining green leaves,and is interesting to the florist in that country, where blue flowers are so rare.—*Mason.*

(5292) MENISPERMACEÆ, *Menispermads*, an important and extensive natural order of Exogenous Plants, considered by some to be Polypetalous, and referred to De Candolle's Thalamifloral sub-class ; by others placed among the *Monochlamydeæ* of that author. The order consists of twining or scrambling shrubby plants with alternate leaves without stipule, and small greenish or white unisexual flowers, often collected in large loose panicles or racemes. The floral envelopes are arranged in a power of three or four, and usually in more rows than one ; whence arises the opinion that these plants belong to Polypetalous Exogens, the inner series being regarded as a corolla. The stamens are either distinct or monadelphous, either equal in number to the inner series of the calyx, and of the same number or much more numerous. The carpels are in most cases three, or some multiple of that number, either distinct from each other or consolidated. The fruit consists of succulent one-celled drupes, with a solitary seed and a horse shoe shaped embryo with thin flat cotyledons. The wood of the stem is arranged essentially upon the Exogenous plan, but has some striking peculiarties. According to M. Decaisne, it has no annual concentrical layers. The woody plates are always simple and do not divide longitudinally, as in other Dicotyledons, but increase each year by the formation of a new woody layer outside the former and inside the liber. The latter ceases to grow after the first year. In *Cissampelos Pereira* and some others, new woody plates, like the first in appearance, but having no spiral vessels or liber, show themselves, at the end of several years, on the outside of the first, and produce around them a concentric circle, a formation which may be repeated a great many times. ('Comptes Rendus,' v. 393.) The order is common in the tropics of Asia and America, but uncommon out of these latitudes. All Africa contains but five, North America six, and Siberia one. The species are universally found in woods twining round other plants. *Cocculi* are most common in the Old World, and *Cissampeli* in the New World. *Menispermaceæ* are usually bitter and tonic plants ; the species of *Cocculus* called *Batis Fibraurea, cinerascens*, and others, are used in their native countries as a remedy for intermittent fevers. *Cocculus palmatus* furnishes the Calumba Root of the shops, a valuable bitter. *Pereiria medica* is used for the same reason in Ceylon as is *Clypea Burmanni* in Malabar, and various sorts of *Cissampelos* in Brazil. But the bitter principle, which in its diluted state is thus valuable, becomes a dangerous poison if concentrated, as in the seeds of *Anamirta cocculus*, the Cocculus Indicus of the shops. There are 11 genera and 175 species of this order.—*Eng. Cyc.*

(5293) MENISPERMINA, a vegetable alkali extracted by Pelletier and Courbe from the *Menispermum cocculus*, or *Cocculus Indicus*, in the shells of the fruit of which it occurs.—*Eng. Cyc.*

(5294) MENISPERMUM (so called from μήνη, the moon, and σπέρμα, seed, from the crescent-like form of its fruit), a genus of the natural family of *Menispermaceæ*, which formerly contained numerous species, many of them valuable for their medicinal and other qualities, such as the Calumba Root, and the berries called *Cocculus Indicus*, which are now referred to the genus *Cocculus*. *Menispermum*, as at present constituted, contains but few species ; and these are climbing shrubs, which have their sepals and petals in quaternary order, arranged in two or three whorls. Male, stamens 16 to 20 ; Female, ovaries 2 to 4 ; drupes baccate, round, kidney-shaped, single-seeded. *M. Canadensis* and *M. Smilacinum* are found in the United States of America, and *M. Dauricum* in the wooded hills of Dauria.—*Eng. Cyc.*

(5295) MENTHA, a genus of Plants belonging to the natural order *Lamiaceæ*, or *Labiatæ*. It has a campanulate or tubular calyx, 5-toothed equal, or somewhat 2-lipped, with the throat naked inside or villous ; corolla with the tube inclosed, the limb campanulate, nearly equal, 4-cleft, the upper segment broader, nearly entire, or emarginate : stamens 4, equal, erect, distant ; filaments smooth, naked ; anthers with two parallel cells ; style shortly bifid, with the lobes bearing stigmas at the points ; fruit dry and smooth.—*Eng. Cyc.* Several of the Mints, remakable for their odour and taste, have long been used in medicine *inter-*

Ἥδυοσμος and Καλὰ μινθα of the Greeks, *nana* of the Arabs), and some as sweet herbs; but it is difficult to distinguish one species from another by the short descriptions given.—*Royle.*

(5296) MENTHA CRISPA. Lin.

Widdalilam, Tam. | Poodina, Duk.

Ainslie's Mat. Med. p. 258.

(5297) MENTHA PIPERITA, Peppermint, is found by the sides of ditches and rivers in Britain, all over Europe, in Egypt, the middle of Asia, India, and North and South America. It has a procumbent ascending branched stem, reddish, quite smooth, or fringed with a very few spreading hairs; petioles generally ciliated; leaves ovate-oblong, or somewhat lanceolate, rounded at the base, deep green, smooth, or hairy on the under side; the upper floral leaves small, lanceolate, subulate, shorter than the flowers; whorls few, lax, the uppermost collected into a short oblong obtuse reddish spike, the lowermost remote, with the cymes shortly stalked; bracts subulate, the outer ones as long as the calyx: pedicels quite smooth; teeth of the calyx hispid, subulate, erect. Peppermint is an aromatic stimulant, and the most pleasant of all the mints. It is employed in medicine for several purposes; the volatile oil is an antispasmodic.—*Eng. Cyc.*

(5298) MENTHA PULEGIUM, Pennyroyal also a British plant, is found in wet ditches in most parts of Europe, also the Caucasus, Chili, and Teneriffe.

(5299) MENTHA ROYLEANA, is much used by the Hill people of the Himalayas.—*O'Shaughnessy, p.* 489.

(5300) MENTHA SATIVA.

Widdatilam. Tam. | Nana, Arab.
Poodina, Duk. | Hibbuk, Arak.

Is prescribed by the Mahomedans in dyspeptic complaints and to stop vomiting —*O'Shaughnessy, p.* 489.

(5301) MENTHA VIRIDIS, Spearmint, is a native of Britain, and is also found in the milder parts of Europe, the Canaries, Cape of Good Hope, and America, both North and South. It is a creeping rooted herbaceous plant, with an erect smooth stem; leaves subsessile, ovate-lanceolate, unequally serrated, smooth, those under the flowers all bract-like, rather longer than the whorls, these and the calyxes hairy or smooth; spikes cylindrical, loose: whorls approximated, or the lowest or all of them distant. This plant greatly resembles *M. piperita*. The colour however is of a deep green. It is also frequently confounded with *M. crispa*, than which it has a stronger and more agreeable odour, but weaker than peppermint. It has not the aromatic odour of that plant, nor does it leave the sense of coolness in the mouth. From it are prepared a distilled water, a spirit, and a volatile oil, which are used as the former.—*Eng. Cyc.*

(5302) MENTHA VIRIDIS. Spearmint. Pahari Poodena. A native of Cashmere but cultivated in the plains for its essential oil and distilled water.—*O'Shaughnessy, p.* 489.

(5303) MENISPERMUM CORDIFOLIUM. Heart Leaved Moon Seed, *Russel.*

Sheendie codie, Tam. | Tippatingay, Tel.
Goolbayl, Duk. | Guduchi, also Amoorta,
Gurcha, Hind. | Sans.
Cita-merdoo, Mal.

Very common in the Ajmeer hills; M. Cordifolium &M. Glabrum are called Gullanchi by the natives indifferently.—*Genl. Med. Top. p.* 211. The powder of the dried tender shoots of this creeper which is bitter, and a little nauseous to the taste, the Tamool Practitioners prescribe as an alterative in cases of depraved habit of body proceeding from visceral obstruction and Jaundice. Dr. Fleming informs us that the Hindoo Physicians consider a decoction of the leaves as a febrifuge and as a tonic in gout. And this plant (which in some parts is called Somalatay) is bruised and put into water and taken by the Brahmins at some of their religious ceremonies.—*Ains. Mat. Med. p.* 112.

(5304) MENISPERMUM CORDIFOLIUM, INFUSION. An infusion of Gulancha is an excellent alterative tonic and diuretic. It is especially valuable in convalescence from fevers, and in secondary venereal affections. Dose, two to four ounces thrice daily.—*Beng. Phar. page* 300.

(5305) MENISPERMUM CORDIFOLIUM, TINCTURE. A tincture of Gulancha, is Tonic and febrifuge. Dose, two to four fluid drachms repeated as required.—*Beng. Phar. p.* 427.

(5306) MENISPERMUM GLABRUM. Nim-gilo Gulancha. A climber found often on Neem trees: the whole plant is very bitter, the stem is chiefly used: six masses are given as a dose, with other ingredients in fevers. An extract called "giloysut," is prepared and much used.—*Genl. Med. Top. p.* 148. Common in Ajmeer. The whole plant is used in fevers as elsewhere in India, every part is very bitter; an extract is prepared called Giloysut, from the stems and leaves.—*Genl. Med. Top. p.* 210.

(5307) MENISPERMUM VERRUCOSUM. Warty-stemmed Moonseed. Found in the Ajmeer hills.—*Genl. Med. Top. p.* 211.

(5308) MENISPERMUM VILLOSUM. Woolly Moon-seed. Found in the Ajmeer hills.—*Genl. Med. Top. p.* 211. I only obtained one specimen of a plant which I am almost sure was the Cocculus Indicus or Plutakenetu, but I could not again obtain portions of the plant, the person who first brought it having forgotten where he first found it.—*Genl. Med. Top. p.* 211.

(5309) **MENYANTHES INDICA**, INDIAN BUCKBEAN.

Bara-phooli, HIND.

In standing water at Ajmeer and Pushkur.—*Genl. Med. Top. p.* 190,

(5310) **MERCURY, QUICKSILVER.**

Abuk, Zibakh, ARAB.	Rassa, MAL.
Shwuyyin, CHIN.	Seemab PERS.
Mercure, Vif-argent, FR.	Rtut, RUS.
Quecksilber. GER.	Rasa, Sutum, Parada, SANS.
Para. GUZ. & HIND.	Azogue, SP.
Argento Vivo, IT.	Rasam. TAM.
Hydrargyrum, LAT.	Rasam, TEL.

Mercury (Hg=202), or Quicksilver, was known to the ancients. The Romans seem to have employed it as a medicine externally (p. 133), as did the Arabs; but the Hindoos were probably the first to prescribe it internally. (v. p. 191.) It is found in China, at Almaden in Spain, and Idria in Carniola, and likewise in South America. It occurs occasionally in metallic globules; usually as the native Bisulphuret or *Cinnabar*; combined with Silver, forming a *Native Amalgam*; or with Chlorine, as in *Horn Mercury*. It is chiefly obtained from the Sulphuret by distillation with lime or with Iron, which combining with the Sulphur, the metal distils over and is condensed.—*Royle*. Quicksilver, or native mercury, is imported from Burmah into Tenasserim, and it is said to be brought to Ava from China.—*Mason*.

(5311) MERCURY, BICHLORIDE OF: CORROSIVE SUBLIMATE. This is much used as a preservative of timber, canvas, &c. from the ravages of mildew, the dry rot and of white ants. A solution is made in the proportion of one pound to four gallons of water, and in this the article to be protected is steeped a variable time according to its nature —*Beng. Phar. p*, 340,

(5312) MERCURIAL PREPARATIONS OF INDIA. *Russa Karpoor*. Several preparations of mercury have been described by the Sanskrit and Tamul writers, especially in the "Purana Sastram," a work on Materia Medica and religious observances. The processes Dr. O'Shaughnessy examined generally led to the production of a mixture of calomel and corrosive sublimate, and the analysis of all the bazar preparations he collected, shews their composition to be a mixture of varying proportions of these substances. The Raskarpur is generally considered to be corrosive sublimate, but on analysis he found that it is usually calomel. Once, however, he met a specimen which was corrosive sublimate of the finest kind. The cause of the uncertainty is to be traced in the different portions of the ingredients recommended by different native writers, and which of course must lead to the results described.—*Beng. Phar. p.* 342.

Rustapushpum.—This is a sort of muriate of mercury, in great repute amongst the Tamuls, and which appears to be administered by them in larger doses than any other preparations of this metal. But it generally happens that through defective manipulation a mixture of calomel and the bi-chloride is formed.—*Beng. Phar. p.* 342.

Shasirum.—This strange compound is administered by the Tamuls in very small quantities; and it ought to be so, as it is evidently a harsh, uncertain, and dangerous preparation. In the mode of preparing it, the vapours of calomel simultaneously rising and meeting the chlorine are converted into the bi-chloride of mercury, the preparation now described.—*Beng. Phar p.* 342.

(5313) MERIANDRA BENGALENSIS; a plant of the family of Labiatæ.

Kafoor ka putta, HIND.

Is in use amongst the people of India.—*O'Shaughnessy, p.* 492.

(5314) MERIANDRA STROBILIFERA. (MURTOO) of the family of Labiatæ has a strong fragrance, and is considered by Royle as very promising.—*O'Shaughnessy, p.* 492.

(5315) MERINO. The term applied to a fine kind of woollen fabric, of various colours. —*Faulk.*

(5316) MEASKHEE FIBRE, BOEHMERIÆ SPECIES (Urticeæ). A fibre is enumerated by Major Hannay ('Journ. Agri-Hortic. Soc.,' vii, p. 217), which he says is called *Mesakhee*, and is an *Urtica*, but not a stinging one. It is a shrubby tree, probably a species of *Boehmeria*, and is very abundant. Its young branches, which are tender and red-coloured, as well as its leaves, are edible. Capt. Thompson had a log-line made of the fibre and found the strength of it quite equal to Russia Hemp, but for want of being properly harvested, the fibres cling so close together that great loss of material takes place in heckling it. He thinks it well adapted for cordage, and if brought into general use ought to bring as much as Petersburgh Hemp." ('Journ. Agri-Hortic Soc.,' viii, p. 60.) Major Hannay says: "The Murrees and others might be induced to bring the fibre for sale; but as the value of this Nettle in the market has not been ascertained, I have only offered at the rate of Rs. 5 per maund which, however, on account of the slow method of manipulation, has not been considered remunerative." (*l. c., p.* 86,) Of Major Hannay's Nos. 9, 7, and 5, the first, which is the foregoing, he says is called *Mesakhee* or *Mejingah*, the other *Mesakhees*. No. 9 has but little fibre and a very rough stem. No. 7 has much the same habits as Bon Rheea., and can be cultivated like it. Its fibre is also of the same character, but white, strong, and durable. It is used for the same purposes. Capt. Dalton, in a letter, dated 20th July, 1854, referring to what Dr. Royle had said

respecting the Wild or Bor. Rheea, writes:—"As he alludes to the batch sent through this office by Major Hannay in 1853, he must refer to the 'Mesakhee,' of which large quantities are procurable, growing wild in Upper Muttock and elsewhere in the district. The instructions regarding the specimen of Petersburg Hemp sent out as a sample are more applicable to this fibre than to the Dom Rheea. I propose to take measures for collecting as much of it as I can get prepared. The cost will be from three to four annas a seer. This might be accompanied by samples of the *Bon Rheea*, *Bon Surat* and other fibres, all prepared to resemble the Petersburgh Hemp. If for these wild fibres we had a good market, the frontier tribes, Singphoos &c., who understand how to prepare them, might be induced to assist in supplying them." The specimens which Dr. Royle had referred to in the above communication were sent under the name of Bon Rheea from India. The two plants, *Bon Rheea* and *Mesakhee*, may be identical or nearly allied species, but this cannot be ascertained without authentic Botanical specimens. Major Hannay distinguishes the two kinds—the *Bon Rheea* being his No. 2 and *Mesakhee* No. 9—in his paper in the 'Journ. Agri-Hortic. Soc.,' vii, *p.* 215.—*Royle. Fib. P. p.* 365.

(5317) MESONA WALLICHIANA. A Labiate plant that grows on the Jyntea Hills, on the ascent, whose bruised leaves smell as strongly of patchouli, as do those of the plant producing that perfume, to which it is closely allied.—*Hooker, Vol.* II. *p.* 314. *Pogostemon Patchouli* has been said to occur in the Khassia Hills of India, but Dr. Hooker never met with it, and doubts the accuracy of the statement. It is a native of the Malay peninsula, whence the leaves are imported into Bengal, and so to Europe.—*Hooker, Him. Jour. Vol.* II, *p.* 314.

(5318) MESPILODAPHNE PRETIOSA. Woods near Para. Inner bark and rind of the calyx very fragrant, resembling cinnamon and bergamot.—*O'Shaughnessy, p.* 547.

(5319) MESUA. The mesua, which in Ceylon is called "iron wood tree," though not large, has an erect symmetrical figure, whose deep evergreen foliage, flowing downward from its cone shaped crest, quite conceals its bowering branches, so that when covered with its rich blossoms, with ivory white petals and deep yellow stamens, it looks like the royal umbrella bespangled with gold; and the Burmese say that their next Budha, *Aree-ma-tuya*, will enter the divine life while musing beneath its hallowed shades, hence it is a favorite tree with the priests who plant it around their monasteries. In Sanscrit it is called nagakeshura, and Sir William Jones remarks of it:—"This tree is one of the most delightful on earth; and the delicious odor of its blossoms justly gives them a place in the quiver of Camadeva, the Hindoo god of love."

To this Moore alludes in the following stanza.

"Then rapidly with foot as light
As the young musk deer's, off she flew
To cull each shining leaf that grew,
Beneath the moonlight's hallowing beams
For this enchanted wreath of dreams;
Anemones, and seas of gold,
And new-blown lilies of the river,
And those sweet flowerets that unfold
Their buds on Camadeva's quiver."

There are at least two different species in the Tenasserim Provinces, *M. pedunculata* and *M. ferrea*. Much confusion exists in our standard works on botany in relation to this last species. The *Mesua ferrea* of Roxburgh is the *M. Roxburghii* of Wight's illustrations; the Mesua tree of Calcutta, Serampore, and neighbourhood.—The *M. ferrea* of Wight's Prodromus is the *M. Coromandelina* of Wight's Icones, and Illustrations.—The *M. ferrea*, of Wight's Illustrations, is the *M. nagaha* of Gardener, the mesua tree of Ceylon; while the *M. ferrea* originally described by Linnæus is *probably* the species found on this coast; but for the lack of books which contain the description of Linnæus, it cannot be affirmed with certainty.—*Mason.*

(5320) MESUA FERREA, Nagsara or Nagkesur. As. Researches, iv. 295. Lin.

Irool Marum, Tam.	Nagacessra, Sans.
Nagasar, Hind.	

The blossoms of this tree, which Sir W. Jones says, is one of the most beautiful on earth, are extremely fragrant, and with them one of the five arrows of Kama the god of love, is tipped.—*Ains. Mat. Med. p.* 163. Under the Tamool name of Irool maram this or another species of Mesua is common in the Nelambore jungles and much used by the natives for building purposes: being durable and not liable to be attacked by insects.—*McIvor. M. E. of* 1857. Mesua Ferrea is cultivated in gardens at Jaepoor, is very ornamental and the flowers are fragrant.—*Genl. Med. Top. p.* 199. This tree is found chiefly in gardens in Bengal, where it flowers in the beginning of the warm season. The dried anthers are fragrant; the flowers and leaves are used in Bengal as antidotes to snake poison.—*O'Shaughnessy, p.* 230.

(5321) MESUA——Irool Marum Mesua sp.: Nelambore Jungles common: much used by the Natives for building purposes: durable and not liable to be attacked by insects.—*McIvor.*

(5322) METALLIC MIRRORS are still in use in Southern Asia.

(5323) METROSIDEROS (from μητρα, the heart of a tree, and σιδηρος, iron), a genus of Plants belonging to the natural order *Myrtaceæ*. It is distinguished from allied genera by the tube of the calyx not being angular, adhering to the ovarium, the limp 6-cleft; the stamens 20-30, free, very long, and exserted; the style filiform, and stigma simple; the capsule 2- or 3-celled,

the cells many-seeded; the seeds wingless. The species are trees or shrubs, with opposite or alternate leaves, with the flowers pedicellate, not adnate to the branches, as they are in the genera *Melaleuca* and *Callistemon*. The last genus with *Angophora*, has been recently separated from *Metrosideros*.—*Eng. Cyc.*

(5324) METROSIDEROS VERA, true Iron-Wood, has opposite ovate-lanceolate acuminated quite glabrous leaves, seated on short petioles; the cymes axillary, pedunculate, many flowered. It is a native of Java and Amboyna, among rocks. The Chinese and Japanese value the wood of this tree, which they apply to many purposes, as the making of rudders, anchors, &c., for their ships and boats. The bark is used in Japan as a remedy in mucous discharges, diarrhœa, and dysentery. It is usually mixed with some aromatic, as Penang cloves, or nutmeg.—*Eng. Cyc.*

(5325) METROSIDEROS POLYMORPHA, has opposite coriaceous leaves, of various forms, glabrous on both surfaces, but covered with a little silky tomentum beneath; the peduncles 3- or many-flowered, terminal and axillary, corymbose; the calyxes and branchlets glabrous or clothed with silky tomentum. The species is a tree, and grows in the Sandwich Islands, and is said to be the plant from which are made the clubs and other weapons employed in warfare by the South Sea Islanders. "The Aki, or Lignum Vitæ of New Zealand, the Rata and the Pohutu Kawa of the same country, are all hard-wooded trees belonging to the genus *Metrosideros*." (Lindley.) Several other species of *Metrosideros* have been described, natives of Australia and the South Sea Islands. *M. lucida*, a beautiful tree, occurs as far south as Lord Auckland's Islands, in lat. 50½ S. The *M. buxifolia* of Allan Cunningham is the New Zealand plant called Aki, and is a rambling shrub, adhering to trees, and climbing by means of its lateral roots to the summits of the loftiest trees in the forests of Wangaroa and the Bay of Islands. In cultivation these plants may be grown in a mixture of loam, peat, and sand. They may be propagated by seeds or cuttings. Ripe cuttings will root in sand under a hand-glass. (Don, *Dichlamydeous Plants*; Lindley, *Vegetable Kingdom*; Burnett, *Outlines of Botany*.)—*Eng. Cyc.*

(5326) METROXYLON SAGO, *Syn* SAGUS KONIGII.

Rambaya, MALAY.

Is cultivated in the Eastern Archipelago, to obtain sago from its wood.—*Seeman.*

(5327) MEZEREUM BARK, MAZRIOON, Rei; Root of Daphne mezereon. Linn.—*Ben. Ph.* 214.

(5328) MEZEREON, OCTANDRIA TRIGYNIA, Linn. This plant is supposed to be included with *Daphne oleoides* under the χαμελαια of Dioscorides. It is called *Mazrioon* in Persian works on Materia Medica, and *Khamela* assigned as its Greek name. Mezereon is a small shrub. Leaves lanceolate, tapering below, smooth, evergreen. Flowers subternate, lateral arranged in a spike-like manner, appearing before the leaves, rose-coloured. Perianth 4-fid, segments ovate acute, tube hairy, Stamens 8, short inserted (1) in the tube of the perianth in two rows. Ovary (2) oval, oblong, with a short style and peltate and stigma. Berry bright red, fleshy, 1-seeded (v. 3), where some of the sarcocarp has been removed, to show the seed.—Woods of central Europe, less common in Great Britain; cultivated in gardens as an ornamental shrub.—Nees von E. 125. St. and Ch. 65. *D. Guidium* (Fr. *Garou*), *D. Laureola*, Spurge Laurel, and other species, are also employed on the continent. The bark of the latter forms much of what is used, even in England, for Mezeroon—Squire, P. J. i. 395. The bark of the root is officinal in the L. and E. P. and is the most efficacious; that of the stem and branches in the Dublin Pharmacopœia; but all these parts as well as the berries, are acrid. The bark is tough and fibrous, as in all Daphnes; it is met with in strips which are of a light greyish colour externally, whitish and shining within; when fresh dried, it has a slight but peculiar odour. The taste, especially of the inner part of the bark, is hot, acrid and durable, though at first a little sweetish.—*Royle, page* 528.

(5329) MICA.

Abraka, SANS. | Ubruck, HINDU.
Tulk, PERS. and DUK.

Several varieties of this beautiful and useful mineral are found in India, especially in Behar, and in the Northern Circars. It readily splits into transparent, elastic flakes. It consists of nearly equal parts of silica and magnesia, and about 6 per 100 of lime. Slips of Mica afford the young chemist a very convenient substitute for platinum foil, in several experiments especially on the effect of heat on organic bodies. —*O'Shaughnessy, page* 694. Mica, is a Mineral belonging to the extensive series of Silicates of Alumina. It occurs in oblique rhombic prisms of about 120° and 60°. The crystals usually with the acute edge replaced. The cleavage is very decided, yielding easily thin elastic laminæ of extreme tenuity. It is found usually in thinly foliated masses, plates, or scales: sometimes in radiated groups of aggregated scales or small folia. The colour is from white through green, yellowish, and brownish shades, to black. The lustre is more or less pearly. Transparent or translucent. Tough and elastic. Hardness 2·0 to 2·5. Specific gravity 2·8 to 3·0. Mica resembles externally talc, and some forms of gypsum. From talc it differs in affording thinner laminæ, and being elastic. It also has

not the greasy feel of talc. The same characters, except the last distinguish it from gypsum, besides it does not crumble so readily on heating. Mica is one of the constituents of granite, gneiss, and mica-slate, and gives to the latter its laminated structure. It also occurs in granular limestone. It is found abundantly in India in the United States, in Russia, in Great Britain, and other parts of the world. It is not often found in large isolated masses, but filling up the veins and fissures of rocks, into the composition of which it enters. It occurs in the oldest rock, as well as in those which are new and possess a crystalline character. In Russia it is used extensively as a substitute for glass, and hence it is called Muscovy Glass. The very thin laminæ are employed for examining objects under the microscope. Hauy states that these laminæ are sometimes not more than the 1-300,000th part of an inch in thickness — *Eng. Cyc.*

(5330) MICHELIA CHAMPACA.

Shemboogha poo. TAM.	Bongas jampacca, MALAY
Champeka pooi, DUK.	Shumpenghie poo, TEL.
Schampakam, HORT. MAL.	Champac SANS.

This beautiful golden coloured flower is held in high estimation by the Hindoos, by whom it is dedicated to Krishna and is one of those with which the five Arrows of Kama the god of love are said to be tipped. Sir William Jones tells us, that its aromatic scent is so strong as to be offensive to Bees, who never alight upon it. Itheede informs us that the powder of the bark of the root of this tree is given to excite the flow of the menses. The wood itself is employed in making drums.—*Ains. Mat. Med. p.* 157. In Pegu *Michelia Champaca* is a large tree, cultivated greatly by the Burmese for the fragrance of its yellow flowers. It is from this that the aromatic *Sumpunghee oil* of the Madras list is obtained —*McClelland* In Tenasserim the streets of the towns and villages are often shaded with the lofty distinguished champac, one of the few trees embalmed in English song of which the poet sings:

> "The maid of India blest again to hold
> In her full lap the Champac's leaves of gold.
> Thinks of the time when by the Ganges' flood
> Her little playmates scattered many a bud
> Upon her long dark hair."

The tree is in flower or fruit a great part of the year, and its rich orange blossoms, which are exquisitely fragrant, are also used by Burmese maidens to adorn their "long black hair." It is the only representative on that Coast of the "Glory of America" — the Magnolia tribe.—*Mason.* The bark of this well known tree is bitter, and aromatic, and on several trials appeared to Dr. O'Shaughnessy to possess the properties attributed to the Magnolia glauca. It may be given in powder in intermittent fevers in doses of from 10 to 30 grains. Its aromatic properties are dissipated by boiling either in water or spirit, and on evaporation a bitter extract remains, which contains tannic and gallic acid.—*O'Shaughnessy, page* 193. The roots of the Uvaria narum are employed in the Mauritius in decoction as tonic and stimulant, and are externally applied for destroying vermin. The powdered seeds of the custard apple are used in Bengal for the same purpose.—*O'Shaughnessy, page* 193.

(5331) MICHELIA NILAGIRICA. MAGNOLIACEÆ, Ill. 5, Icon. 938.

Shemboogha marum, TAM.

This tree is rare in the Walliar forests, being alpine in its tendencies. It is common on the Neilgherries, wood said to be good as regards strength, but too highly hygrometrical to be useful in other form than rafters or beams, though close and fine grained. —*Wight.*

(5332) MICHELIA RHEEDII. PEELA CHUMPA OR GOLDEN FLOWERED CHUMPA.

Sampaughy Marum, TAM.

This is a handsome tree with beautiful golden coloured flowers, held in high estimation by the Hindoos, the bark of the root of the tree is used medicinally in some female complaints.—*Riddell.* The Michelia Rheedii, (*Wight*) Sumpaghymaram, yields a pretty olive colored mottled wood, close grained, without being heavy, and well suited for cabinet making. It is, being tried in Bombay for ship building purposes. At the Madras Exhibition of 1855, a very large plank was contributed by Capt. Cunningham of the Mysore Commission, obtained from *Michelia Rheedii* (Sumpaghy). The extraordinary dimensions, (length 11½ feet, breadth 4½ feet, thickness 3 inches.) which the tree assumes, though rarely, and the ornamental character of the wood, were well shown in that specimen, which may with justice be declared *unique*. This remarkably large specimen was apparently derived from a tree of very great age.—*M. E. J. R.*

(5333) MICO. A sort of butter prepared in Japan from the Dolichos bean.—*Simmonds.*

(5334) MICROLÆNA SPECTABILIS is a tree found at the foot of the Himalayas, which yields fibres for rope-making.—*Royle.* It is one of the most numerous timber trees of Pegu, and yields, it is said, a fibre fit for making rope, but the Burmese do not make use of it.—*McClelland.*

(5335) MICROPUS (Swainson), a genus of Birds belonging to the family *Brachypodinæ*, the first sub-family of the *Merulidæ*, according to his arrangement. [MERULIDÆ.]

(5336) MICROPUS CHALCOCEPHALUS. IXOS CHALCOCEPHALUS, Temm. The male has the whole head covered with a sort of hood of metallic black with violet reflection; the neck,

the shoulder, the back, and wings, dull gray or lead colour; breast deep gray, which becomes brighter on the other lower parts of the body; wings black, but the secondaries gray, bordered with whitish on the exterior barbs; tail gray with a transverse black band, and terminated with a broad white border. Length 9 inches 4 lines. Female: less lively in colour. It inhabits Java, where Van Hasselt found it in the wild and woody district of Bantam.—*Eng. Cyc.*

(5337) MIGNONETTE. RESEDA ODORATA.—A general favorite in all countries, may be had in great luxuriance on the plains during the cold months, does not like to be transplanted, and ought invariably, whether in pots or flower beds, to be sown where intended to flower: requires an open soil and free drainage, sometimes lives through the hot season, if sheltered by a high building.—*Jaffrey.*

(5338) MIGRATION.—The reader, curious on the subject of the migration of Indian birds, should consult a paper by H. M. Hodgson, Esq., in the 18th volume of the Asiatic 'Researches,' Part II., 122.—*Cal. Rev.*

(5339) MILDEW, PUCCINIA GRAMINIS, a fungus attacking corn, in England, the spores of which appear to enter the grass, not by the roots, but by the stomata.—*Hassall.*

(5341) MILK HEDGE.—Euphorbia Tirucalli.

(5342) MILK OF PALM NUTS. This popular term, is the albumen of the seed when in a liquid state; and which, when the fruit is quite ripe, appears as a solid, white or yellowish mass, and is then termed the kernel. This albuminous fluid or water, when the nut is taken from the tree early in the morning and whilst the dew is still upon it, is a cool and delicious draft. It is slightly effervescent and gently aperient.—*Seeman.*

(5343) MILLET.

Dukhn, ARAB.	Milium, Panicum Miliaceum, LAT.
Kungoo, BENG.	Kuma[illegible], MAL.
Tana-hul, CYNG.	Arzun[illegible], PERS.
Navonay, CAN.	Milho Mindoo, PORT.
Cay Khe, COCH-CHIN.	Kangu, Priyangu, SANS.
Bal, Rawla, DUK.	Mija, SP.
Mil. Millet, FR.	Tenny, TAM.
Hirse, GER.	Coraloo, TEL.
Kang, GUZ. HIND.	
Miglio, IT.	

Millet of various kinds is met with in the hottest parts of Africa, in the South of Europe, in Asia Minor and in the East Indies. In India they hold a rank second to rice alone, and those chiefly cultivated are as follows,

Botanical Names.	English.	Hindoostanee.	Tamil.
Setaria italica.	Italian millet.	Kala kangnee.	Tenny.
Setaria germanica.....	German millet.....	Kora kang..... ...	....
Panicum miliaceum... ...	Common or little millet...	Sawee; cheena; Warree... ...	Varagoo.
Pencillaria spicata.....	Spiked millet.	Bajree.....	Cumboo.
Sorghum vulgare..... ..	Great millet...	Jowaree.....	Cholum.
Eleusine coracana.....	Raggy.....	Natchnee Ragee...	Kavaroo.

The native West Indian species are P. fasciculatum and oryzoides. Setaria Germanica is the most common in America, where millet is chiefly grown for making hay, half a bushel of seed to the acre is the usual quantity, sown broad-cast and harrowed in, but to procure the finest quantity of hay, an additional three or four quarts of seed is sown. The ordinary yield of crops is about a ton to a ton and half of hay to the acre, but it should be cut as soon as it is out of blossom, for if it stands later, the stems are liable to become too hard to make good hay. In Southern India, there are three kinds of Jowaree, white, green and red, the straw is of great bulk and goodness, and furnishes good provender for cattle being preferable to that of rice. It is however given dried, as the green plant is injurious. Among culmiferous plants and legumes used in the East, are the Panicum italicum, Eleusine coracana (the meal of which is baked and eaten in Ceylon under the name of Corakan flour), and Paspalum of several varieties. The pigeon pea (Cytisus Cajan;) and a very valuable and prolific species of bean called the Mauritius black bean (Mucuna utilis), growing even in the poorest soil, is cultivated in India and Ceylon. Sorghum vulgare is the principal grain of Southern Arabia and the stems are also used extensively for feeding cattle. The plant bears its

Indian name of joar, or jwari, and is cultivated throughout Western Hindostan. Mr. Simonds says Job's tears (Coix lachryma) is another cereal grass, native of the East Indies. Millet of different kinds is met with in the hottest parts of Africa, in the South of Europe, in Asia Minor, and in the East Indies. One is a small yellowish seed growing in dense panicles or clusters, the produce of a grassy plant with large and compact seeds growing to the height in India of seven or eight feet. The millets are known to Europeans as petit mais, tropical crops. In India they hold a second rank to rice alone, and in Egypt perhaps surpass all other crops in importance. In Western Africa they are the staff of life. The red and white millets shown by Austria, Russia and the United states, at the Great Exhibition, were beautiful, and Ceylon exhibited fair samples. Turkey abounds in small grains. Panicum miliaceum and P. frumentaceum are the species grown in the East Indies. Loudon says there are three distinct species of millet, the Polish, the common or German, and the Indian. Setaria Germanica yields German millet. The plants are readily increased by division of the roots or by seed, and will grow in any common soil. The native West Indian species are *P. fusciculatum* and *oryzoides*. Millet receives some attention in New South Wales. In 1844, there were 100 acres of land under cultivation with it, and the amount grown in some years in this colony has been about 3,500 bushels. In the United States millet is chiefly grown for making hay, being found a good substitute for clover and the ordinary grasses. It is a plant which will flourish well on rather thin soils, and it grows so fast that when it is up and well set it is seldom much affected by drought. It is commonly sown there in June, but the time of sowing will vary with the latitude. Half a bushel of seed to the acre is the usual quantity, sown broadcast and harrowed in. For the finest quantity of hay, it is thought advisable to sow an additional quantity of three or four quarts of seed. The ordinary yield of crops may be put at from a ton to a ton and a half of hay to the acre. It should be cut as soon as it is out of blossom; if it stands later, the stems are liable to become too hard to make good hay. The variety known as German millet is that most common in North America. It grows ordinarily to the height of about three feet, with compact heads from six to nine inches in length, bearing yellow seed. There are some sub-varieties of this, as the white and purple-seeded. The Italian millet, *Setaria italica*, is larger than the preceding, reaching the height of four feet in tolerable soil, and its leaves are correspondingly larger and thicker. The heads are sometimes a foot or more in length, and are less compact than the German, being composed of several spikes slightly branching from the main stem. It is said to derive its specific name from being cultivated in Italy, though its native habitat is India. It is claimed by some that this variety will yield more seed than any other, and the seed is rather larger, but the stalk is coarser, and would probably be less relished by stock. If the greatest amount of seed is desired from the crop, it is best to sow it in drills, two to two-and-a-half feet apart, using a seed drill for the purpose. This admits of the use of a small harrow or cultivator between the rows, while the plants are small, which keeps out the weeds. The crop will ripen more uniformly in this way than broadcast, and enables the cultivator to cut it when there will be the least waste. The seed shatters out very easily when it is ripe, and when the crop ripens unequally, it cannot be cut without loss, because either a portion of it will be immature, or, if left till it is all ripe, the seed of the earliest falls out. It should be closely watched, and cut in just about the same stage that it is proper to cut wheat, while the grain may be crushed between the fingers. It may be cut with a grain cradle, and, when dry, bound and shocked like grain; but it should be threshed out as soon as practicable, on account of its being usually much attacked by birds, many kinds of which are very fond of the seed. The seed is used in various European countries as a substitute for sago, for which it is considered excellent. It is likewise a valuable food for poultry, particularly for young chickens, which from the smallness of the grain can eat it readily, and it appears to be wholesome for them. In some countries millet seed is ground into flour and converted into bread; but this is brown and heavy. It is, however, useful in other respects, as a substitute for rice. A good vinegar has been made from it by fermentation, and, on distillation, it yields a strong spirit. Millet seed—the produce of *H. saccharatum*—is imported into this country from the East Indies for the purpose chiefly of puddings; by many persons it is preferred to rice. It is cultivated largely in China and Cochin-China. The stalks, if subjected to the same process that is adopted with the sugar-cane, yield a sweet juice, from which an excellent kind of sugar may be made. Millet will grow best on light, dry soils. The ground being first well prepared, half a bushel of seed to the acre is ploughed in at the commencement of the rains in India. The crop ripens within three months from the time of sowing. The usual produce is about 16 bushels to the acre. The Canary Islands export annually about 212,400 bushels of millet.

Great Indian Millet, or Guinea Corn.—This is a native of India (the *Sorghum vulgare*, the *Andropogon Sorghum* of Roxburgh), which produces a grain a little larger than mustard or millet seed. It is grown in most tropical countries, and has peculiar local names. In the West

Indies, where it is chiefly raised for feeding poultry, it is called Guinea corn. In Egypt it is known as Dhurra, in Hindostan and Bengal as Joar and in some districts as Cush. In Lower Scinde joar is very extensively cultivated, as well as bajree (*H. spicatus*). It is harvested in December and January, requires a light soil, and is usually grown in the east, after *Cynosurus coracanus*. The natives of Mysore reckon three kinds known as white, green, and red. The red ripens a month earlier than the rest, or about four months from the time of sowing. Near Bengal, Bombay, and elsewhere, in Eastern India, sowing is performed at the close of May or early in June. A gallon and a third of seed is sown per acre, and the produce averages 16 bushels. This grain, though small, and the size of its head diminutive, compensates for this deficiency by the great bulk and goodness of its straw, which grows usually to the height of 8 or 10 feet. It is sometimes sown for fodder in the beginning of April, and is ready to cut in July. It is said to be injurious to cattle, if eaten as green provender, the straw is therefore first dried, and is then preferable to that of rice. This grain is frequently fermented to form the basis, in combination with goor or half made sugar, of the common arrack of the natives, and in the hills is fermented into a kind of beer or sweet wort, drank warm.

Holcus spicatus, the *Panicum spicatum* of Roxburgh, is cultivated in Mysore, Behar, and the provinces more to the north. From one to four seers are sown on a biggah of land, and the yield is about four maunds per acre. It is sown after the heavy rains commence, and the plough scres to cover the seed. The crop is ripe in three months, and the ears only are taken off at first. Afterwards the straw is cut down close to the surface of the soil, to be used for thatching, for it is not much in request as fodder. Being a grain of small price, it is a common food of the poorer class of natives, and really yields a sweet palatable flour. It is also excellent as a fattening grain for poultry. The *Poa Abyssinica* is one of the bread corns of Abyssinia. The bread made from it is called *teff*, and is the ordinary food of the country, that made from wheat being only used by the higher classes. The way of manufacturing it is by allowing the dough to become sour, when, generating carbonic acid gas, it serves instead of yeast. It is then baked in circular cakes, which are white, spongy, and of a hot acid taste, but easy of digestion. This bread, carefully toasted, and left in water for three or four days, furnishes the *boza*, or common beer of the country, similar to the *quas* of Russia.—*Simmonds.*

(5344) MILLELE. A wood of Ceylon probably specifically identical with sapoomilile, with which it coincides in very respect.

(5345) MILLINGTONIA HORTENSIS. Bignoniaceæ. An elegant tree growing to the height of fifty feet, is in blossom towards the close of the rains, and the seeds ripen in March. The bark is of a soft spongy nature, the wood is white, firm, and close grained.—*Riddell.*

(5346) MILLINGTONIA SIMPLICIFOLIA, is also scarce, but found in the Forests of the Pegu Valley. Its properties as a timber are valuable from its weight and strength. Wood, white-colored, adapted to every purpose, house-building.—*McClelland.*

(5347) MILL STONES.

Pierres meulieres, Fr.	Schernowoi kamen, Rus.
Muhlsteine, Ger.	Muelas de molino. Sp.
Mole macine, It.	

Are large circular stones, which, when put in motion by machinery, grind corn and other articles.—*Faulkner.*

(5348) MIMOSA, a genus of Plants belonging to the natural order *Leguminosæ*. It has polygamous flowers; petals 4 or 5, connected together into a 4 or 5 cleft funnel shaped corolla; stamens inserted in the base of the corolla, or in the stipe of the ovary, equal in number to the lobes of the corolla, or double or triple that number; legume compressed, flat, 1- or many-jointed; joints 1-seeded; ribs permanent; stipules petiolar; leaves bipinnate, with one or more pairs of pinnæ, each pinna bearing 2 or many pairs of leaflets; flowers rose-coloured or white, disposed in heads. The leaves are frequently sensible to touch, as in the Sensitive Plant. The species are very numerous.—*Eng. Cyc.* Of this genus of plants, many are to be found all over the country, the leaves of some of the species are remarkable for being sensitive to the touch. The pink and yellow flowers of one of the small shrubby kinds are particularly beautiful in the rains, readily grown from seed in any soil.—*Riddell.*

(5349) MIMOSA, or WATTLE-BARK, is procured from different species of mimosa, which grow in Australia and New Zealand. It is sometimes imported in the form of fluid extract, as well as bark. The leather produced by its means is of good quality, but of bad colour. The bark must be finely ground, or it does not give up the whole of its tannin to warm water.—*Simmonds.*

(5350) MIMOSA ABSTERGENS, Soap nut. Roxb.

The fruit.

Seekayah, Tel.	Seeyakkoy, Tam.
Secka kai, Hind.	

The leaves.

Shee a kai elley, Tam.	Sheeka-kayo, Duk.
Sik kai ka paat, Duk.	Ghodasala, Sans.

This is a long, flat pod or legume, containing separate, small, oval, dark coloured seeds, and is

considered by the Native Practitioners as a most valuable medicine. In taste it somewhat resembles the soap nut, but is more acid, less bitter, and has a singular pungency. Its qualities are said to be deobstruent and detergent; and I am inclined to believe that it is also an expectorant. It is commonly prescribed by them in cases of Jaundice and other biliary derangements, and is, besides, used by them like the soap nut, for washing the head. The small leaves of this prickly shrub have a pleasant acidity, and are frequently put into pepper water, when it is found necessary to keep the bowels open or work off bile. The pod is usually prescribed in electuary, in doses of about the size of a small walnut, every morning for three days.—*Ainslie's Mat. Med. pages* 111 *and* 260.

(5351) MIMOSA ADENANTHERA.—The UNARMED MIMOSA. Nat. Lajwanta species.

(5352) MIMOSA ALBA.—The WHITE MIMOSA.

(5353) MIMOSA PUDICA.—The Sensitive Plant.

Lajuk Hind. | Total vadic. Tam.

Common in gardens, and grows readily from seed, color of the flowers pale pink.—*Jaffrey. M. pudica* has a prickly herbaceous stem, with the petioles and peduncles more or less beset with stiff hairs or bristles; leaves somewhat digitately pinnate, with 4 pinnæ, each pinna bearing many pairs of linear leaflets. It is a native of Brazil, and is commonly grown in gardens under the name of Sensitive Plant, the leaves falling on the slightest touch. The roots of this plant and its allies emit a most offensive smell, resembling the odour of a sewer at the time of impending rain.—*Eng. Cyc.*

(5354) MIMOSA SAPONARIA. The legumes of *M. saponaria*, according to Royle, form considerable article of commerce in India on account of their saponaceous qualities. [SENSITIVE PLANTS.] (Lindley *Vegetable Kingdom*; Don, *Dichlamydeous Plants.*)—*Eng. Cyc.*

(5355) MIMOSA PROCERA.

Padda Patscroo, Tel.

A Native of Coromandel where it grows to be one of their largest trees. *Roxb.*—*Rhode M.S.S.*

(5356) MIMOSA SCANDENS.—The climbing Mimosa.—*Riddell.*

Gela, Hind. | Gilla liga, Tam.

(5357) MIMOSA SENSITIVA, the Sensitive Plant, has prickly stems and petioles; leaflets ovate-acute, dotted with adpressed pili beneath, but glabrous above. It is a native of Brazil. The flowers are rose-colored and tetrandrous. The leaflets are sensitive to touch, but not so much so as the following species.—*Eng. Cyc.* This vegetable wonder will grow in almost any situation and soil, raised easily from seeds.—*Jaffrey.* In Tenasserim, where "garden flowers grow wild," near deserted habitations the pink globular heads of the sensitive plant may be often seen peeping through the grass. It is cultivated by the Burmese, and is quite naturalized.—*Mason.*

(5358) MIMOSA XYLOCARPA.

Conda Tungedoo, Tel. | Betada swamuniki Vriksha, Can.
Maici Avarei, Tam.

It is called Pingadoo in Pegu where it is used for knees, crooked timbers &c. in ship building. A large stately timber tree; a native of various parts of India. It blossoms during the hot season, at which period it is nearly destitute of foliage. The timber is remarkably strong and durable—*Roxb.* In the Vizagapatam district this wood is used for common purposes, it generally is faulty in the centre, it is not a bad wood for furniture, is well adopted for handles of tools &c. the average size at Vizagapatam is 12 inches in diameter and fifteen feet long; on the Godavery it is seldom obtained exceeding 8 inches in diameter and generally is faulty in the centre; it is used for posts.—*Rhode M. S. S.*

(5359) MIMOSEÆ, a sub-order of Plants belonging to the natural order *Leguminosæ*, whose flowers are regular, the stamens long, usually indefinite in number, and hypogynous, and the flowers valvate in æstivation. They are in many cases polygamous, and their leaves are always more or less compound. The principal genus of the division is the *Acacia. Mimosa* itself consists of a considerable number of species many of which are remarkable for the irritability of their leaves, a curious property which has always rendered them objects of interest. [SENSITIVE PLANTS.] The species commonly cultivated for the exhibition of this phenomenon is the *Mimosa pudica*, a South American annual. Among the useful plants belonging to *Mimoseæ*, and not included in the genus *Acacia*, are the *Inga saipida*, *I. dulcis*, *I. biglobosa*, and some others, whose pods contain a sweet nutritious fæcula, which renders them fit for food: and several kinds of *Prosopis*, the astringency of whose pods and bark renders them valuable for tanning purposes. In general, in the northern hemisphere, *Mimoseæ* are confined to tropical countries, or to those which have a high summer heat: but in the southern hemisphere they extend beyond such limits as in Van Diemen's Land, where Acacias, called Wattles, are the commonest wood. [LEGUMINOSÆ.]

(5360) MIMULUS. SCROPHULARINÆ. Monkey flower.—*Riddell.*

(5361) MIMULUS CARDINALIS. These plants are well suited for flower borders, the colours are chiefly blue, red and yellow, easily grown from seed in any garden soil, it takes its name from *Mimo*, an ape, the seed bearing some resemblance to the face of a monkey.—*Riddell.*

(5362) MIMUSOPS ELENGI. SAPOTACEÆ.

The Tree.

Maghidam maram, TAM.	Pogada mannoo, TEL.
Taindoo or Bacul, Mulsari, DUK.	Moogali mara, CAN.

An ornamental tree with dark green oblong alternate leaves, and white fragrant flowers; common.—*Wight.* A tree of moderate size, cultivated for the oil obtained from its fragrant flowers. The wood is little known. Wight No. 40, Mysore 23,33, Nellore 87, Travancore 209, Rajahmundry 54, Hort. Gard. 54.—*M. E. J. R.* The quality of the wood, says Mr. Rohde, is unknown to me, and, being so much a cultivated plant, it is not probable that it is much used and is therefore little known.—*Rohde.* This species of mimusops, a rare ornamental tree, is much valued by Burmese ladies for its small delicate sweet-scented blossoms, which they string in chaplets for the head.—*Mason.* It thrives well at Ajmeer, growing to a large size, the flowers are delightfully fragrant, and the wood is very hard and durable, the foliage is beautiful and evergreen. The berries are eaten sometimes by the poor. This tree would be very ornamental in compounds.—*Gen. Med. Top. p.* 190.

(5363) MIMUSOPS ELENGI. Lin. Colebr. 92.

The Flower.

Maghadam poo, TAM.	Mulsari ka pool, HIND.
Poghada, TEL.	Bacula, SANS.
Bolsarika pool, DUK.	

The small pale brown sweet smelling flowers of this most beautiful and ornamental tree are celebrated in the puranas and even placed amongst the flowers of the Hindoo paradise.—*Ains. Mat. Med. p.* 158.

(5364) MIMUSOPS OIL. MIMUSOPS ELENGI. A medicinal oil, obtainable in tolerably large quantities in some parts of the country. At the Madras Exhibition of 1855, it was exhibited by W. E. Underwood, Esq. as a new oil, but is known in England.—*M. E. J. R.*

(5365) MIMUSOPS HEXANDRA.

The Tree.

Pala marum, also patta, TAM.	Rajun, HIND.

This is a tree common in the Deccan, and is generally planted by the Mussulmans with the Elengi; the wood is much used where strength and toughness are required; the fruit is eaten by the natives —*M. E. J. R. Riddell.*

(5366) MIMUSOPS HEXANDRA. ROXB.

The Fruit.

Palay pullum, TAM.	Pala pundoo, TEL.
Keernie ka pull, DUK.	Cheerie, SANS.

This is the olive shaped reddish colored fruit of a very large tree. It is eaten (but not much sought after) by the poor, and grows in the woods of the Northern Circars.—*Ainslie, p.* 229.

(5367) MIMUSOPS KAUKI, OBTUSE-LEAVED MIMUSOPS.

Kirnee, HIND.

Cultivated at Ajmeer and Kotah, the tree becomes very large and is very handsome, the small fruit is eatable, the wood is fine-grained and hard.—*Irvine, page* 190. In the Deckhan, this tree grows to a large size, and is generally planted in groves: the fruit, which is about the size of a small olive, is of a yellow color when ripe, after the rains, and contains a sweet clammy juice, eaten chiefly by the Natives.—*Riddell.* This dried fruit is occasionally seen among the Chinese, brought from Singapore, and some of the seeds produce trees, which, judging from their leaves, can be no other than that now under notice.—*Mason.*

(5368) MINERAL SPRINGS.

1. SULPHURETTED.

Malacca, thermal (Ward).

Spring, 27 miles N. from Hazareebagh, thermal, (H. H. Wilson).

Bum Buklesir, thermal, 16 miles, W. and S. of Sooree in Bheerbhoom, (Sherwill).

Jorya Booree, not far from Chaunch, near meeting of Barakur and Damooda rivers, thermal (Oldham).

Tantloie near it, on other side Damooda, thermal.

Tata Pani, Sirgoojah, Chota Nagpore, thermal (Breton).

2 springs at N. base of Maha Deo Mountains, Nerbudda, thermal, (Spilsbury).

Well at Gwalior, (Col. Todd).

Below Landour, (Murray).

At Sonah, 30 miles from Delhi, thermal, (Ludlow).

At Lousah, in Noorpore, (Marcadieu).

At Bishisht in Kulloo, thermal, (Gerard).

In the Bukh Ravine Salt Range, thermal, (Fleming).

At Jubba in Salt Range, 10 miles E. of Indus (do.)

Chihalee Pass W. of Indus below Kalibag, (do).

Mittah near Esau Khail W. Bank of Indus (do.)

Peer Mungal and Gazee Peer in Scinde, thermal, (Major Baker and Lt. McLagan.)

At Lukkee Pass, near Schewan, thermal, (Gibson).

Within high water mark in Kuttywar, (Sandwith),

Temple of Somnath in Guzerat, (Col. Todd.)

Arowlee in the Concan, thermal, (Duncan).

At Bhadrachellum on the Godavery, thermal, (Heyne, Malcomson).

At Chittoor, slightly thermal, (Hardy).

2. SALINE.

Several springs at Sooroojkoond near Belcuppee and Burkutta, Grand Trunk Road, (Sherwill and Hooker), thermal.

Tevah in Kangra district, (Marcadieu).

Mukhdoor Rusheed in Moultan, (Edgeworth).

Shahpore near Jhung, (Neelmadub Mookerjee).

Lahard Khad on Sutledge above Roopur, (Wade).

Universal throughout Salt Range, (Fleming).

Sumoondur and Kullur kuhar lakes in Salt Range? (Fleming).

Doozeekoostuck Scinde, thermal (Viccar).

Ooch Scinde, (Viccary).

Lukkee Pass, (Gibson).

Well at Banda? (Prinsep).

Near Hyderabad Deccan, (Voysey).

a. brine.

Sambher lake?

Many springs in Salt Range, (Fleming).

Old spring near Jeypore in Assam?

Brine springs in Becaneer and Jessulmeer, (Irvine).

Cachar Hills.

Peer Mungul Scinde, (Baker and McLagan).

b. alkaline.

Loonar lake, 50 miles from Jaulnah, (Malcomson)?

At Mean Meer, and others in Punjab, (Baddely).

Kairi water, or Soda water wells in Ajmeer, (Irvine),

Well at Jowali Mookhi? (Marcadieu).

c. aluminous.

Well below Landour, (Murray).

d. iodine.

Traces of iodine in well at Jowali Mookhi and Arlun in Kangra, (Marcadieu).

Ditto Thunga Bara near Hurripore, (ditto).

Strong iodide of potass well at Jowali, [Mr. Marcadieu states, that though bronchocele is very common in the district—the inhabitants of Jowali are exempt from it.] (do.)

e. lime.

Many in Murree Hills above Rawul Pinddee, (Fleming).

Peeth in Halla mountains thermal, (Viccary).

Kye in ditto, thermal, (A. Young).

Near Sunjabundia, Kurnool, thermal, (Newbold) temperature decreasing.

f. silicious.

Burrare and Bheem Bhand, Kurruckpore Hills thermal, (Sherwill and McClelland).

3. CHALYBEATE.

At Dallhousie, Chumba, (Clemenger).

Rhotas near Jhelum, (Fleming).

Bakh ravine in Salt Range, (ditto).

Chibalee, W. Bank of Indus, (ditto).

At Munnee Karn, (Edgeworth).

At Nagconda, Simla hills, (ditto).

Below Landour, (Murray).

On Rungeet river, Darjeeling (Liston).

Rungnoo river, 4 miles E. by N. of Darjeeling, (Withecombe).

Bangalore, (Garrard).

Ramandroog hills near Bellary, (Mayer).

Near old town of Attaran, Moulmein thermal?

4. THERMAL SPRINGS WITH NO IMPORTANT INGREDIENTS, OR IMPERFECTLY KNOWN, SOME OF THEM PROBABLY CARBONATED.

Hot springs at Cannea in Ceylon. Temp. variable?

Hot water fountain at Tavoy,
Ditto at Lunkyen in ditto,
Ditto at Sienlee in Martaban. } Prinsep.

Near Kaline Aurig Martaban, (Low.)

Hot spring on Attaran river Tenasserim, (Piddington).

Hot springs on the Palouk river and at Pee, between Mergui and Tavoy, some sulphuretted, (Major W. McLeod).

Springs at Numyan near Prome.

Between Mecaday and the Arracan hills, (Phayre).

Seetacoond, near Chittagong.

Utteer, 30 miles from Poorie, (Brander).

Kaljhurnee, Maharoo, Hathulleah, Nonbhil, between Rajamahal and Sooree (Sherwill).

Lacarakoonda 21 miles S. W. of Sooree in Beerbhoom, (Sherwill).

Tantlooee 16 miles N. W. of Sooree, on Sidh Nulla, (Sherwill).

Springs at Katkamsandi, old Benares Road, (Everest).

Pinarkoon, Ramgur, (Breton).

Seetacoond, Monghyr.

Paharpoor, Kurruckpore hills, (Sherwill).

Rajgeer and Guriuk, N. by E. of Gyah, (Sherwill).

On Rungeet river, (Darjeeling Guide).

Near Bagin river in Pana district Bundlecund, (Franklin)

Two hot springs in Alwar country, one 15 miles W. by S. from Alwar, one 20 miles N. E. of Jeypore, (Capt. Bellew's survey.)

Mineral springs at Machery? (Col. Todd.)

At Seetabaree, in Harowtee, also cold springs, (Col. Todd).

At Jumnootrie, Gungootrie, Kedernath, and at Badrinath, in Ghurwal.

Hot springs near Nutpa, Booktee and Jauree, valley of Sutledge, (Gerard).

Opposite Sonee banks of ditto, (Prinsep).

Hot spring at Silol, Kangra, (G. T. Survey).

Munneekarn in Kulloo and hot spring further up the Parbutti. (Mr. Edgeworth informs me that the water where it issues from its source, is of the temperature of 207° Fahrt. It is therefore one of the hottest known springs

Some of the hottest of these are the Geysers 180°, Sooroojkoond 190°, the Petersquelle in the Caucasus 195°, spring on Palook river 196°, and what Humboldt discovered and describes as the hottest spring in the world, Guanaxuata in Mexico 207°. The boiling point of water at the elevation of Munneekaru is much below that point. Rice is cooked in the spring at Jumnootrie 194°, at about 11,000 feet above the sea, and in many others of inferior temperature.)

Kulat in Kulloo, (Gerard).

Lower range of Sooliman mountains, (Fleming).

Peer Muggen Alligator Tank, 13 miles from Kurachee, (Carless).

Juggun and Deyrah, N. Scinde, (Kirk).

Springs at the base of the Halla mountains, Scinde, (A. Young).

Oonee, Central range of Kuttywar, variable temp. (Gibson).

Oonopdeen and Soonoopdeen in Satpoora Range, (Briggs).

From near Surat to Rajapore many hot springs, at Mahar, Rutnaghery Mat, &c. more than 12 in number (Duncan.)

At Kair and Urjunnah, Deccan, (Malcomson).

At Byorah (Malcomson).

5. PETROLEUM.

Pegu?

Arracan, Paidong 5 miles from Ramree (Bogle).

Island of Cheduba.

Assam, at Jeypore and five other places, (Hannay).

Sylhet, (Inglis)

Kaffir Kote, Algud ravine W. bank of Indus, (Fleming).

Jubba, N. side of Salt Range, 10 miles E. of the Indus, (do.)

Jowali Mookhi, (Gerard).

Three springs in Dooloo, eastward of Gogra, (do.)

The preceding list, which, though a rude general classification has been attempted, has no pretension to being any thing more than a catalogue, includes, it is hoped, most of the mineral sources in India and its dependencies, of which accounts have been published. The names attached to the notices have been added; generally they are those of the discoverers, or rather describers; but in some instances of the analysers of the waters. Some springs, such as the Monghyr Seetacoond, have been so long known, that it is uncertain who the original describers were. A few have been communicated to me by friends. I have to acknowledge my particular obligations, to Capt. Sherwill for information about the Rajmahal and Bheerbhoom springs, to Mr. Edgeworth about those in Kulloo, Dr. Fleming the ones in the Salt Range, and Mr. A. Young those in Scinde. About 30 springs are believed to be here noticed for the first time. Major Sanders gave me some valuable information from the Maps in the Quarter Master General's Office: and I also was kindly allowed access to the Surveyor General's Office. I have thus, although I cannot hope to have escaped mistakes, been able to verify most of the localities, which in many instances, owing to strange transmutations of names, has been no easy matter. Three or four are from the records of the Foreign Office and Medical Board. It seemed useless, with reference to the generally imperfect nature of most of the observations, to attempt to include an abstract of such analysis as have been made, or even a record of the temperature of the thermal springs, or of the nature of the rocks or soil from which they issue. This was the less necessary, as it is understood that these points will be fully investigated in the course of a general inquiry about to be made by order of the Government of India. Petroleum wells have been included in the list, as they are of some commercial value, although they perhaps cannot properly be called *mineral* springs. Their medicinal use, which is known to the Natives of India, is also now almost abandoned except in some cutaneous affections. Even in the present imperfect state of our knowledge of the mineral waters of India, a few points of interest are suggested by the table, which I shall now consider. What districts are richest in mineral waters? These appear to be, the Tenasserim Provinces, a district round Hazareebaugh stretching in almost every direction for about 130 miles, in many places literally teeming with hot springs, the upper part of the Jullunder Doab, or rather the hills beyond its Northern boundary, the salt Range, and Northern and

Western Scinde; next is the Concan, and, though not to be compared with any of the foregoing, the peninsula of Guzerat. The deficiency of mineral sources in the Southern portion of the peninsula of India, and throughout the great central trap formation, is remarkable. They are found at every elevevation, from within high water mark to a height of 12,000 feet. What kinds of mineral waters are most common? More than half of those in the Table are thermal. The most frequent of all appear to be the Hot springs without any very strong mineral impregnation, which are so abundant in the Tenasserim Provinces, and in the Hazareebaugh districts, in some parts of the Himalaya, in the Concan, also in Scinde, where, as in many other places, an impregnation with carbonate of lime is common. One or two such have been found in Rajpootana and the Deccan. The Sulphurous Springs, appear to be pretty equally diffused; several in Hazareebaugh, some in the Nerbudda, some in the Concan and Guzerat, some in Scinde and the Salt Range, many at the base of the Himalayas, and in the upper part of the Jullunder Doab. Only one has been noticed in the Madras Presidency, (Chittoor is scarcely an exception to this,) and no true one in Tenasserim. The great majority of them are thermal. The Saline springs are chiefly found in Scinde and in the higher portion of the Punjab; they usually contain common salt with some sulphate of soda and small quantities of other salts, when they are not simply brine. Traces of iodine are found near Kangra. Throughout Rajpootana and in some parts of the Punjab, the wells are abundantly impregnated with soda. Some of the springs in Kemaon contain mineral impregnations, but scarcely to an extent to be considered saline. Scarcely any strong saline ones are thermal. The few thermal salines are chiefly calcareous, and one or two silicious. There appears to be a general deficiency of Chalybeates, and there is no one district in which they have been found more frequently than another, unless the outer ranges of the Himalayas; the wells in the Neilgherries are said often to have a trace of iron. None of the Indian chalybeates are thermal, and none of those known, except that at the beautiful spot Nagconda, appear to be strong ones; but it is difficult to suppose, especially with reference to there being no want of iron in India, that other sources of this description and of more powerful virtues will not be discovered. I am told there are many undescribed chalybeates in the Himalayas. The Murree hills contain scarcely any, and it is to be hoped that the one at Chumba, may prove of value. It is much to be regretted, that none of the agreeable Acidulous carbonated waters, such as the Selters, commonly called Seltzer water, which are abundant in some parts of Germany, have been found in India, where they would be so grateful. Some of the thermal springs, as the Seetacoond, at Monghyr, the water of which is highly prized and often carried on long voyages, are probably slightly carbonated, and observers talk of Indian springs effervescing, for instance the so-called chalybeate at Bangalore. When, however, it is considered, that almost all the strongly carbonated Springs in other parts of the world are found in the neighbourhood of extinct volcanoes, as in Auvergne, the Rhine Provinces, the Caucasus, or near active ones, as at Ischia, they are scarcely to be looked for in India. [Hot springs are not necessarily indices of volcanic action; they are most common at points of great displacement of strata, or at the junction of stratified and unstratified rocks. There seemed to be no sufficient grounds for considering the Loonar lake volcanic. Former observers could not discover scorix or lava, but it appears that Dr. Bradley in 1851 found both, See a paper by Dr. Buist in Trans. Bombay Geogr. Society, from which I have got much useful information. He has collected a large list of thermal springs, and connects them with volcanic agency.] By analogy, some might be expected to be found in Arracan, or in the Pegu and Tenasserim Provinces, the first being, and the other two being nearly included in the belt of volcanic action that runs up the eastern side of the Bay of Bengal, terminating in Barren Island and the mud volcanoes; but I never heard of any when I was stationed in Arracan, although I visited some of its volcanoes. I may now inquire how far these waters have been had recourse to, by the natives of the country, and to what extent they are likely to be of use to Europeans? In the great majority of instances, they have only been regarded by the natives of the country as emanations of the deity, and as objects of poojah or worship. Wherever there is a hot spring, there is pretty sure to be a temple, visited by pilgrims. Many have, however, been used medicinally. Some of those, which appear to be most resorted to, for their healing virtues, are the springs at Malacca, those at Sonah near Delhi, where considerable buildings have been erected for the convenience of bathers, at Munnee Karn, and at the Lukkee Pass. All of them are thermal, and except Munnee Karn, are sulphuretted, and natives have undoubtedly faith in them in certain cases. Such springs might easily at a small expense be made more extensively useful to natives. Europeans can scarcely be said to have ever made a fair trial of any of the mineral springs of India. Mr. Ludlow in 1826, suggested that the wells at Sonah should be made use of for European soldiers. Dr. Murray's spirited attempt in 1843-44, to employ the sulphuretted and chalybeate springs in the

valley below Landour for the benefit of the Invalids at that sanatarium, never, I think, met with the support it deserved, and the situation of the springs at the bottom of a hot and confined though picturesque valley, was a very important obstacle to success. In 1846 I found them all but abandoned. That more attempts of the kind have not been made, that springs of as high virtues as those so prized in Europe, should have been neglected, must no doubt be a matter of surprise to people who have not visited India, to foreigners, to whom of all but the poorer classes a visit to a bath is a yearly necessity, and to Germans, who publish annually some 30 new works on their watering-places, but not to those who are aware of the many practical difficulties to be contended with in this country. It is not, however, generally known in Europe, nor indeed in this country, that mineral springs are so abundant in the East. Above 100 separate localities have been included in the Table, and it would be easy to extend the list, if I were to insert waters beyond the bounds of British India. There are hot springs in Ladak, Nepal, and Sikkim; at Uchebul in Cashmeer, and hot sulphur springs near Rajourie, in Goolab Sing's territory. See Cunningham's Ladak. Hooker's Travels, Mrs. Hervey's Travels &c. In what direction are we to look as the most favorable one for the establishment of a spa in India? The mere absence of strong ingredients in the water, as in the Tenasserim and many of the Hazareebaugh hot springs, would be no essential obstacle to success in their use, for some of the popular European baths, as Matlock, Wildbad, Pfeffers, and Bad Gastein, are very deficient in salts, yet are found efficacious in many affections, being chiefly used for bathing. But the absence, at most seasons of the year, of a bracing climate, at the generality of the thermal springs in India, diminishes the chance of their ever proving of utility to Europeans. Unless the climate of Hazareebaugh, w[illegible] European visitors, there is not the sea, alone[illegible]s of interest in the neighbourhood to this remar[illegible] *Macpherson M. in No. iii, India* have been for the [illegible] *Science, page* 205, *Oct.* 185[illegible]ountain of Parisnath, [illegible]INT. [illegible] miles off, were adapte[illegible] [illegible]me of the mineral springs which a[illegible] Frauen murze, [illegible]nt in the adjacent country, had been discovered in its clefts. But all evidence goes to show, that the space on the ridge at its summit, is far too limited for more than two or three bungalows, and there would be much difficulty in procuring a proper supply of drinking water for any number of people. Besides, it is very doubtful whether in the plains of Bengal, its height, although equal to Mahableshwar, about 4,500 feet, is a sufficient elevation for a sanatarium. The opening of the Railway to Raneegunge will bring two or three sulphuretted springs within reach of Calcutta.

That at Chaunch is only twenty miles from the terminus, and about three miles off the Grand Trunk Road. It is prettily situated, not far from the Pachete hills, and there is a colliery near. But there is a much more abundant and hotter one called Tanloie, on the banks of the Damooda, two or three miles off. Those at Bum Buklesir are about 15 miles from Mungulpore, and the same distance from Sooree: they are further off the high road, but are more powerful and abundant. The hot spring at Lakarakoonda is not far off, and there is said to be another near at Kisshun. The elevation of all them may be about 300 feet above the sea level. The Europeans resident at the Collieries count the district healthy, except during the rains. Of these places, Bum Buklesir, is particularly deserving of an early investigation, for no analysis of its waters has yet been made. There are four or five springs: the temperature at least of the hottest, which is 162°, exceeds that of the most popular springs of the kind, Aix-la-Chapelle, or Bareges and Cauterets in the Pyrenees. During the four cold weather months the climate is probably not inferior to that of any of those places in their short bath season. Indeed, but for the peculiar arrangements of society in India, depending on Europeans being birds of passage, and not colonists, but for the absence here of any season of general relaxation from business, these wells might, for all I can see to the contrary, that is, if there be no local objection to them, have long ago been found of much utility to the inhabitants of Calcutta. The truth is, the facility of communication with England and of going to sea, enjoyed by Calcutta people, has led to indifference about the sanitary resources of the country, and to the neglect of Cherra Poonjee and Darjeeling, or rather to their never being fully appreciated, and to the abandonment of the only sanatarium they had on the sea-coast, Poorie; not that it was ever in very high favor. A few of the residents of Cuttack still go there, during the hot months, but I never hear of any one visiting it from Calcutta. In fact, sea bathing, or any other kind of bathing, except for purposes of ablution, is scarcely known in Bengal, and probably not much practised in any part of India. Swimming baths are scarcely an exception to this statement. Yet how refreshing is the following description, extracted from the dry Madras Road Book—"Cootallum (not very far from Cape Comorin) is a large place with several bungalows close into the hills. The well known cataracts are close at hand. The lower cataract falls from a height of 200 feet. The average temperature of the water is 72° to 75°, and invalids derive great benefit from bathing in it. The bathing-place is under a shelving rock, affording the most delightful shower-bath possible. The

climate is particularly enjoyable to Europeans in June, July and August. The scenery is splendid; there are in all three falls, the highest being 2,000 feet above the sea." Amherst, too, or Negrais, should either be hereafter employed as a sanatorium, may indeed be useful to the occupants of our new provinces, but will never be any great resource to the inhabitants of Bengal. Of Negrais in particular a very favourable account appeared in an interesting article in the *Calcutta Review*, five years ago. Negrais has since then been reoccupied, but not exactly in the way anticipated by Mr. J. R. Martin, when he wrote on the subject. But, to return from what would have been a digression, if sanatoria and watering-places were not so intimately connected with each other, if we look next to Scinde, which abounds in mineral waters, the situation of the province and its climate alike preclude the hope of their ever being extensively useful to Europeans, though they might be more employed for sepoys, and the people of the country. There is also no great prospect of any of the other wells in Bombay becoming available. The thermal springs of the southern Concan do not appear to be powerful, and they have no advantage as to climate. For Madras there seems to be no hope, but in making the most of the chalybeates at Ramandroog. The European Regiment and Artillery might well be moved there from Bellary—so far, at least, as one without local knowledge can judge. There is table land 3,198 feet above the sea; climate cool, invigorating and healthful, 13° to 14° cooler than Bellary; the table land is 2,735 yards long by extreme breadth 996 yards. The climate must make the sulphur springs of Bhadrachellum useless for Europeans, even if in other respects they were promising. What then is the Land of promise? The higher portion of the Jullundur, a tract abounding in mineral wells of all descriptions, where the icy stream of the Parbuttie, close to the boiling fountain of Munneekarn, which rises in a jet at an elevation of 5,587 feet, could furnish Russian baths, if they were desired, and where the immediate vicinity of a chalybeate is not to be forgotten: where some are reported to contain Iodine or Bromine (the asserted presence of less than $\frac{1}{3}$ of a grain of bromide of potass, with the merest trace of iodine, in 16 ounces of the water, was the making of the Saline of Kreutznach), and where some must possess the advantage of an almost European climate. In this district also and on the Banks of the Beas, is Bishihi, at an elevation of 6,681 feet, with an ample thermal sulphuretted source. After touching on the subject of the use of grapes, Dr. McPherson continues; but to get grapes in abundance, (and the vine blight has not yet reached Asia,) they would have to proceed further into the Himalayas than any of the springs I have enumerated, beyond the influence of the periodical rains, to the beautiful valley of Chinee, of which Mr. Grant has furnished so pleasing an account, and where he describes the grapes as being plentiful, excellent, and exceedingly cheap. There too may yet be found sources of value, for Gerard says, there are a few mineral springs impregnated with salt, iron and alum, that may possess medicinal virtues, and the famous wells of Zungsum, at the meeting of the Speetee and Parati rivers, 4 miles North of Shealkhur, where inscriptions in the Tartar language on tablets of stone describe the particular virtues of each spring, are scarcely beyond the limits of Kunawur.

Bum Buklesir.—So interesting does this locality appear to me, with reference to its vicinity to Calcutta, that I do not hesitate to add to this paper some detailed information respecting it, which I owe to the kindness of Capt. Sherwill. Dr. Sheridan of Bheerbhoom has had the kindness to write me an account of a recent visit to the springs. It tallies with Capt. Sherwill's; only one went in the rains, when the country was under water, the other in the cold weather. Bum Buklesir is a pretty and curious spot, easily accessible. It is healthy and not jungly, being situated in a well-cultivated country, with a little jungle to its South. It is one mile from the large town of Tantipara, on the banks of a small nullah, called the Buklesir. There are five or six hot springs, the whole group called Bum Buklesir. The hot wells that have been surrounded with masonry walls are immediately on the North or right bank of the nullah. There are numerous hot springs in the bed of the nullah only to be seen in the dry season, giving out the well-known smell of sulphuretted hydrogen, with which the air is tainted. Near the hot springs there are several cold ones, all flowing from a tough gneiss rock. The hot and cold springs are only separated by a few feet from each other. The body of water ejected from the hottest well is very considerable, being about 120 cubic feet per minute; the[n] runs from innumerable [illegible] mud and [illegible] In the mas[s] [illegible] 162°, a g[reater] [illegible] spring is [illegible] 3 or 400 feet from [illegible] of bathers is a large pucka tank which is supplied by two springs, one hot and the other cold; so that at one end the water is warm, at the other cold, and in the centre tepid. The stream of the nullah is about 50 yards across, with a brisk current, and it retains its heat below the springs for a considerable distance; its temperature was 83° in the month of December, when the temperature of the air was in the shade 77°. The sand of the stream some little way from the spring, and at the depth of six inches, is intolerably hot to the hand. Extending for about 200 yards along the right bank of

the stream, are 320 small brick and mortar Viharahs or temples, built by various pilgrims, each containing a Priapus or emblem of Maha Deo. Only one temple has any pretension to architectural elegance. Numerous attendant Brahmins, who are most importunate beggars, loiter about the temples, engaged in bathing in the hot stream, or watching the cremation of dead bodies, which operation is constantly being carried on. Tantipara is a fine substantial village, with most of its inhabitants engaged in preparing silk for the Calcutta market; there is an indigo factory besides a police chokee and abkaree station; a short way off is the large town of Dobrajpore, offering a good market for English piece goods, and producing a large supply of fish from its numerous tanks. Between it and Bum Bucklers, and in the town of Dobrajpore, large naked and picturesque masses of granite and gneiss protrude through the soil, occupying altogether about a mile square. The scene is a very curious one, and there is a good view of the surrounding country from the top of one of the rocks, on which is a Grand Trigonometrical Station about 60 feet high. In the opposite direction, but further away, is Nagore or Jy Nuggur, a large town; the greater part of it has gone to decay, as is shown by its falling mosques, half-filled and weed-choked masonry tanks, and ruined buildings which almost approach to palaces in extent. The famous Nagore wall or entrenchment, extends in an irregular and broken figure round the town of Nagore, at a distance of about 4 miles; its length is about 32 miles. At Lakarakoonda, about 5 miles off, is a warm spring, temp. 85°. Near the feeble stream which carries away its waters is a curious Hindu cut stone temple, which is fast falling into ruin. I trust that I have quoted at sufficient length from Capt. Sherwill's interesting notes and reports to show, that if Bum Buklesir were fitted for the reception of European visitors, there is no lack of objects of interest in the neighbourhood.—*Dr. John Macpherson M. in No. iii, Indian Annals of Medical Science, page* 205, *Oct.* 1854.

(5369) MINT.

Hibbuk, Nana, Arab.	Frauen murze, Ger.
Baume Verte, Fr.	Menta romanna, It.
Pudeena, Nana, Guz. Hind.	Nana, Pers.
	Widdatilum, Tam.

A well-known leaf, chiefly used for culinary purposes in England, as well as in India, where it is easily grown. Mint is occasionally prescribed by Mahomedan practitioners in dyspeptic complaints, and to stop vomiting. Several kinds are distinguished, all remarkable for their peculiar odour and taste.—*Faulkner.* The common sorts are three, Spear-mint, Pepper-mint and Penny Royal. The first is generally used for culinary purposes: it may be propagated by layers, or cuttings, or parting of the roots; it requires a moderate proportion of water. In the rains a small black caterpillar attacks the leaves, and will destroy the whole bed if not removed by hand, or flooding the beds, when the insect becomes detached from the leaves, and is easily destroyed.—*Riddell.*

(5370) MIRABILIS JALAPA, Marvel of Peru. Belle de nuit.

Patrash, Tam.	Gool bajee, or Gulabbas, Hind and Duk.
Reso, Japan.	Krishna keli, Beng.

Cultivated as an ornament in all the gardens of Bengal. Considered an aperient by the native doctors. Drs. Hunter and Shoolbred tried it without satisfactory results, and Dr. O'Shaughnessy's experiments lead him to believe it destitute of any efficacy. It is at best an uncertain cathartic. The roots of this plant were long regarded as the source of the true Jalap. They are considered purgative, their taste is acrid and nauseous, and they abound in starch; the seeds also contain this principle in such abundance that they have been proposed as an alimentary article. The Mirabilis dichotoma and longiflora are reputed to possess similar properties.—*O'Shaughnessy, p.* 511. This plant is very beautiful though very common, and known as the Marvel of Peru. The flowers are of various colours, red, white and yellow, also variegated red and white, yellow and white. The root when dried is prepared for medicinal use. It becomes in a short time quite a weed in a garden. Is propagated by seed, and in any soil.—*Riddell.*

(5371) MIRCHEE. Capsicum Frutescens. Capsicum.

(5372) MISHME TEETA. Golden thread-root of Assam. Roots of Coptis teeta.—*Beng. Ph.*

(5373) MISSEE, a powder made from gall-nuts: sulphate of copper; steel filings: myrobalans, and the pods or gum of the keekur tree: the Hindoo and Mahomedan women use it in staining the teeth black.—*Herklots.*

(5374) MISWAK, a substitute in India for a tooth brush, made from a twig of the Margosa: the rough acharantes: careya arborea, Phyllanthus multiflorus; and Palmyra.—*Herklots.*

(5375) MOCHA STONES AND MOSS AGATES are semitransparent calcedony, including various ramified forms, produced by iron, manganese, bitumen and chlorite or green earth, but sometimes also, as has been proved by Daubenton and MacCulloch, produced by the presence of real vegetable bodies, such as Confervæ and Mosses. The finest are found in Guzerat, but received their name from having been brought from Mocha, in Arabia.—*Eng. Cyc.*

(5376) MOCHEAL, the Tamil name of a Ceylon tree which is about twenty inches in diameter,

and eight or ten feet high. It is used in native boats &c. It produces a fruit from which oil is extracted.—*Edye. Ceylon.*

(5377) MODEL OR PUTCHA OOTOO WOOD.

(5378) MOHAIR.

Moire, FR.	Moerro, IT.
Mohr, GER.	Mue, Muer. SP.

The hair of the Angora goat, famous for being soft, fine as silk, and of a silvery whiteness. It is made into camlets, &c.—*Faulkner.*

(5379) MOHUL WOOD.

Mohul, HIND.

(5380) MOHUNNANEE WOOD OIL.

(5381) MOHUR OR ASHRUFFE. A gold coin, of India, now rarely seen, of fifteen rupees value.

(5382) MOLASSES, TREACLE.

Melasses, FR.	Melasso, PORT.
Syrup, GER.	Patoka sacharnaja, RUS.
Kakwee, GUZ HIND.	Meil de azucar, SP.
Meilazzodi zucchero, IT.	

The uncrystallisable part of the juice of the sugar-cane, separated from the sugar during its manufacture. It is of a brown or black colour, and a sweet taste. Molasses is used in preparing the coarser sorts of preserves, and on the Continent and in India, in the preparation of tobacco.—*Faulkner.*

(5383) MOLINDA CANESCENS.

Korive : Sapindus tetraphyllus, TEL.

A native of the Circar mountains ; flowers about the time the sapindus does. The wood of this tree is white and not so serviceable as that of the *Sapindus* rubiginosus. Roxb.—*Rohde, M.S.S.*

(5384) MOMORDICA, a genus of Plants belonging to the natural order *Cucurbitaceæ*. The flowers are monœcious, yellow or white ; the staminiferous flowers have a 6-cleft calyx, with very short tube, a 5-parted corolla, tridelphous stamens, with connate anthers ; the protilliferous flowers have three sterile filaments, the styles bifid, the ovary 3-celled ; the fruit opens with elasticity when ripe ; the seeds compressed, reticulated.—*Eng. Cyc.*

(5385) MOMORDICA CHARANTIA, CUCURBITACEÆ.

Kurilla, DUK.

(5386) MOMORDICA CHARANTIA.

Punney Fodaylang-kai, TAM.

This vegetable is very commonly cultivated by the natives at the commencement of the rains, the fruit is from ten to fourteen inches long, and from two to four in diameter; the edges are curiously notched and ridged, the flavour is bitter, and it requires to be soaked before being cooked. —*Riddell.* The green fruit used in curries, &c., it grows about 1 foot or 15 inches length, commonly cultivated, known by the name of small snake gourd ; before cooking it is generally steeped in salt water.—*Jaffrey.* In Tenasserim, two or three varieties of momordica, a fruit the size of a cucumber covered with tubercles, are used in curries.—*Mason.* In Ajmeer, cultivated in the rains.—*Gen. Med. Top. p.* 209. This is a creeper, sown at the commencement of the rains, and may be continued during the cold season ; it is a bitter fruit, very rough skinned, and from four to five inches long ; the edges have a very wrinkled appearance ; when ripe it is of a beautiful deep red and yellow. The natives fry and eat them, but they are principally used in curries ; they require to be soaked in salt and water before dressing. They sell from one to two pice a seer.—*Riddell.*

(5387) MOMORDICA CHARANTIA, VAR. FRUCTIBUS OBLONGIS.

Comboo pagulkai, TAM.	Pandy pavel, HORT. MAL.
Lumba carala, DUK.	Deerga Karavullie, SANS.
Commoo Kakakaia, TEL.	

This is a very valuable pleasant tasted and wholesome hot vegetable though perhaps a little too bitter. It is about four or five inches long and of a wrinkled and scabrous appearance outside. The natives sometimes make curry of it, but prefer it fried. In some parts of the country the Tamool name of this article is pronounced Comboo pawakia.—*Ainslie, p.* 238.

(5388) MOMORDICA CHARANTIA, *Var.* MURICATA.

Pavay-kai, TAM.

The bitter gourd. Commonly cultivated and used in curries, said to be very wholesome ; another fruit called Nerree pavay-kai, is sold in the bazaars, I have seen nothing but the fruit, and take it to belong to Curcurbitaceæ.—*Jaffrey.*

(5389) MOMORDICA DIOICA.

Angakara Gudda, TEL.

This is a smaller species and round-fruited, but differs little from the former : both are much cultivated by the natives for their curries.

(5390) MOMORDICA DIŒCA. DIŒCIOUS MOMORDICA. A species of momordica with small muricated fruit, is occasionally eaten by the natives.—*Mason.*

(5391) MOMORDICA MIXTA.

Gol-Kakra, BENG.

This is erroneously named *Makal* by Ainslie, and as he also by mistake applies the same term to the colocynth plant, many errors have originated in attempts to introduce the Indian colocynth into medical practice in India. The fruit of the Gol-Kakra is large, red, and thorny, contains a yellow insipid pulp, is totally inert as a medicine, and is indeed occasionally used for

food in Bengal. *Makal* is the correct name of Trichosanthes palmata.—*O'Shaughnessy, p.* 349.

(5392) MOMORDICA MURICATA. Bura Hurela. HIND. cultivated.—*Gen. Med. Top* p. 209.

(5393) MONEY. The current and convenient principal coin of the Malay and Philippine Archipelagos is at present, and has long been, the hard Spanish dollar, the peso duro of the Spaniards; and that with globes and pillars, containing 3709 grains of pure silver, and worth in sterling money 5179 pence, has an universal preference. The English rupee and Dutch guilder are but of local currency and always, more or less, at a discount. The dollar, in the native languages, is known by various names; the Malays usually call it real, which is, no doubt, an "abreviation of the Spanish real de a ocho, or a piece-of-eight." The common name with the Javanese is ring git, which literally means "scenic figure."—*Crawfurd Dict. page* 285. A great variety of small coins of brass, copper, tin and zinc are in circulation throughout all the islands. The most frequent of these is the Dutch doit, of which about 300 ought to go to a Spanish dollar. The intrinsic value of all such coins, however, having no relation to their assumed one, and being usually over issued, they are generally at a heavy discount. The small coins of Palembang, Achin, Bantam, and Queda are of tin. Those of the latter place go under the name of tra, which is, however, only the word "stamp" or "impression." Of these 160 are filed on a filament of ratan, of which 8 strings or 1280 coins are considered equivalent to a hard dollar. In Bali and Lomboc the currency consists of Chinese Zinc coins with a hole in the middle for filing them on a string, each string having 200, and five of these called a siah, that is, "one thousand," being the highest denomination of money in the reckoning of the inhabitants of these islands. Their value rises, and falls in the market according to the supply, like any ordinary article of merchandise; so that a Spanish dollar will sometimes buy 800 of them, but often as few as 500 only. All these small coins are generally known by the Javanese name of pichis, corrupted pitis by the Malays, a name which had extended to the Philippines.—*Crawfurd Dict. p* 285. The only native country of the Archipelago in which a coin of the precious metals seems ever to have been coined, is Achin. This is of gold of the weight of nine grains, and of about the value of 14d. sterling: to which European traders have given the name of a mace, a corruption of the Malay mas, itself a corruption of the Sanscrit, masha, the name of an Indian weight. All the coins of this description that have been seen are inscribed with Arabic characters, and bear the names of the sovereigns under whom they were struck, so that they are comparatively modern.—*Crawfurd Dict. p.* 286. Previous to the arrival of Europeans, the natives of the Archipelago generally, had no other coin than the small bits of copper, brass, tin, or zinc, already named. The Javanese appear to have coined some of their own money, as we find from many examples excavated from old temples, and other places.—*Crawfurd's Dictionary, page* 286.

(5394) MONGHYR, is celebrated for its iron manufactures, especially of muskets, in which respect it is the Birmingham of Bengal. Generally speaking, these weapons are poor, though stamped with the first English names. A native workman will, however, if time and sufficient reward be given, turn out a first rate fowling-piece. The inhabitants are reported to be sad drunkards, and the abundance of toddy-palms was quite remarkable.—*Hooker Him. Jour. Vol.* 1 *Page* 87.

(5395) MONITORIDÆ, or MONITORS, a family of Lacertian Reptiles: the name Monitor has been given to the typical genus of this family in consequence of the supposed warning given by them of the vicinity of crocodiles. The warning of these Monitory Lizards was said to be a hissing or whistling; but the better opinion is, that they obtained credit for this monition solely from the accident of their haunts, which are for the most part in the neighbourhood of the waters, and consequently bring them sometimes into company with the destructive and gigantic reptiles above mentioned. The Monitors have teeth in both jaws, but none on the palate. Cuvier divides them into two groups, and Fitzinger into three, under the names of *Tapinambis*, *Varanus*, and *Psammosaurus*. Dr. J. E. Gray makes the *Monitoridæ* the first family of his *Leptoglossæ*, or Slender-Tongued Lizards. Character of the Family.—Head with minute polygonal shields; teeth adnate to the inner side of the jaws; tongue elongate, slender, retractile into a sheath at its base; scales small, roundish, placed in cross rings, those of the sides like those of the back; legs 4, strong; toes 3-5, compressed, unequal; thighs porcless; supraorbital plate bony. The species are inhabitants of the Old World, and frequent the banks of rivers. The Asiatic genera and species of the 'British Museum Catalogue' are as follows:—

Odatria Gray.—Nostrils ovate, longitudinal, sub-anterior; teeth compressed, acute. Tail elongate, round, not keeled above; scales large, sharply keeled, sub-spinose. Back with elongate narrow keeled scales. Ventral shield elongate. Toes rather unequal, elongate.

O. Timorensis (*Monitor Timorensis* Gray; *Tapinambis viridimaculatus* Daud.), the Timor Odatria. Black, yellow-dotted, dots forming rings and spots; head yellow and black-dotted. Scales over the orbits small, granular; of forehead larger. Ventral shields nearly as broad as long. Tail slightly compressed above, sub-triangular; base of tail unarmed. Is a native of Timor.

Empagusia, Gray. Nostrils large, oblong, oblique, in front of the muzzle. Tail as long as the body head, tapering, roundish, with a double-edged keel above; scales sharply keeled. Toes rather short, sub-equal. Teeth acute. Scales ovate, keeled. Head short.

E. flavescens, Gray (*Monitor flavescens*, Gray; *Varanus Russelii* Schlegel; *U. Piquotii*, Dum. et Bib.; *M. exanthematicus*, var. *Indica*, Schlegel), the Indian Empagusia. Olive, with yellowish cross-bands. Head-shields sub-equal; eye-brows with a central series of larger plates. It is found in Nepaul.

Varanus, Merrem.—Nostrils oblong, rather oblique in the centre, between the apex of the muzzle and the orbits. Tail elongate, compressed, with a double-edged keel above. Toes elongate, unequal, strong. Head elongate.

a. Shields over the orbits small, sub-equal.

U. heraldicus: *Monitor heraldicus*, Gray, the Heraldic Varan. Black, with cross rows of pale-eyed spots; pale beneath; black-banded. Shields over the orbits small, sub-equal. It is a native of India.

U. lunatus, the Lunated Varan. Nostrils large, nearly central; shields over the orbit small, sub-equal. Dark brown, with lunate bands directed backward on the neck and forwards on the body, and with cross-bands on the tail; belly and under side of tail whitish. It is found in India.

U. ornatus, the Philippine Varan. Nostrils large, central; shields over orbit small sub-equal. Olive; neck and front of the body with pale-spotted broad black cross-bands; the hinder part of the body and tail with pale spots. It is a native of the Philippine Islands.

U. Dumerilii; *Monitor Dumerilii*, Muller; Dumeril's Varan. Brown, with obscure cross-bands, with a black spot on side of neck. Shields of the head and over the orbit nearly equal, moderate. Scales large, convex. It is a native of Borneo.

U. rudicollis, the Rough-Necked Varan. Nostrils large, nearer the orbit than the end of the muzzle; shields over the orbits nearly square, the hinder central ones rather larger. Scales of the back triangular, keeled; of the neck large, prominent. Muzzle elongate. Black, with white streaks on back of neck, and bands across the back. It is found in the Philippine Islands.

b. Scales over the orbit small, with a central longitudinal series of larger plates.

U. nebulosus (*Monitor nebulosus*, Gray; *M. nebulatus*, Schlegel), the Coloured Varan. Nostrils large, rather nearer the orbit than the end of the muzzle orbital shield with a large series; back of neck with converging dark streaks. It is a native of India.

c. Tail triangular, compressed, and with a doubly-toothed crest above. Nostrils small, round. Aquatic.

Monitor, Gray (*Polydædalus*, Wagler; *Varanus*, Fitz.)—Nostrils small, round, in the middle, between the apex of the muzzle and the front angle of the eye. Tail elongate, compressed, with a double edged keel above. Toes elongate, unequal, strong. Teeth rounded.

M. Dracœna, Gray (*Lacerta Dracœna*, Linn. *Stellio Salveguardia*, Laur.; *Tupinambis Benga*; *lensis*, Daud.; *T. Indicus*, Daud.; *T. Cepedianus* Daud.; *Varanus guttatus*, *U. punctatus*, and *U. Argus*, Merrem; *M. gemmatus*, Guerin) the Indian Monitor. Brown; black-spotted or yellow-eyed when young. Nostrils central; scales over the eyes flat, small, sub-equal; of the head rather larger. It is a native of India.

M. Gouldi Schlegel (*Hydrosaurus Gouldii* Gray), Gould's Monitor. Neck with two yellow streaks on the side; scales over the eyes small, granular; of forehead larger. Ventral shields small, longer than broad. It is found in north-western Australia.—*Eng. Cyc.*

(5396) MONKEYS. The Chinese are skilful in teaching the smaller kinds of monkeys various tricks and persons carrying them around the country to entertain the populace with their antics are often met. Mr. Breton gives one picture of their adroitness and usefulness in picking tea in Shantung from plants growing on otherwise inaccessible acclivities which if not misrepresented rests on doubtful authority. One of the most remarkable animals of this tribe is the "donc" or Cochin-chinese monkey (Simia nemæus) which is said to occur also in Kwangsi. It is a large species of great rarity, and remarkable for the variety of colors, with which it is adorned. Its body is about two feet long and when standing in an upright position its height is considerably greater. The face is of an orange color and flattened in its form. A dark band runs across the front of the forehead aud the sides of the countenance are bounded by long spreading yellowish tufts of hair. The body and upper parts of the forearms are brownish grey, the lower portions of the arms from the elbows to the wrists being white, its hands and thighs are black and the legs of a bright red colour, while the tail and a large triangular spot above it are pure white. Such a creature matches well for its grotesque and variegated appearance with the mandarin duck and gold fish also peculiar to China.—*Williams' Middle Kingdom, p.* 247.

(5397) MONKEY BREAD TREE.—ADANSONIA.

(5398) MONKEY FLOWER.—DIPLICUS AND MIMULUS.

(5399) MONKSHOOD.—ACONITE.

(5400) MONOCERA GRIFFITHII.—MONOCERA. In the southern provinces of Tenasserim, there is a species of monocera which bears flowers similar to the Elæocarpus.—*Mason.*

(5401) MOODOOGA OIL, BUTEA FRONDOSA. The seeds of this tree yield a small quan-

city of a bright clear oil, which is sometimes used medicinally —*M. E. J. R.*

(5402) MOOCHEE, Hindoo castes, in Bengal, shoemakers, or saddlers, in the Dekhan, painters, book binders, saddlers, &c.

(5403) MOOCHERUS. A gum resin yielded by the *Bombax Heptaphyllum*. It occurs in knotty, opaque, dark-brown pieces, often with internal cavities. The roots of this plant constitute the *Suffeid mooslie* of the Indian bazars. Vide article Mooslie White, is a laxative and as such given to children.—*Faulkner.*

(5404) MOONJA, SACCHARUM MOONJA, a grass indigenous to India, it is collected after the rainy season, it is possessed of great tenacity and is employed for tying up cattle at night, for ropes for the Persian wheels : and the Benares and Indus boat-men make tow ropes of it, and it is used as rigging, in all the vessels above Sikkim. It would form an ample supply of half stuff for paper makers.—*Royle.*

(5405) MOOLAY KEERAY, AMARANTUS POLYGAMUS, Lin.

Molay kceray, TAM.	Molakoora, TEL.
Cholai baji, GUZ.	Chuolaee, HIND.
Rujgheere, ke baujee DUK.	Shakinee, SANS.

(5406) MOOLOKARANG VARAY PUTTAY; TODDALIA ACULEATA : AMARANTUS SPINOSUS. LIN.

Moolloo keeray, TAM.	Mooloo Duntoo koora, TEL.
Cateahrajaheera ke baujee, DUK.	Cuntaka, Shakenie, SANS.

(5407) MOONG AROOD. PHASEOLUS MONGO. Green Gram. This is chiefly grown in the upper parts of Hindoostan ; it is eaten by the natives dressed in various ways.—*Jaffrey.*

(5408) MOONG PHULEE. ARACHIS HYPOGÆA. Earth-nut. Ground nut ; Manilla nut : the legumes contain the nuts ; they are small and white, and require to be roasted before eaten ; they are not in much esteem.—*Riddell.*

(5409) MOON STONE. Some of the "cat's eyes" that are brought for sale by the Ceylonese, are made of adularia or moon-stone, a variety of felspar found in Ceylon resembling opal. In Europe it is often sold for opal.—*Mason.*

(5410) MOORCH'HUL. A club-like fan, made of peacocks feathers, used by the great.—*Herklots.*

(5411) MOORDAR SUNG. Litharge is not made at Ajmeer, though there are lead mines : it is brought from Delhie : used in ointments and in oil paintings : two seers for one rupee.—*Genl. Med. Top. page* 146.

(5412) MOORIES, BLUE. These cloths are principally manufactured in the Districts of Nellore and at Coonatoor in the Chingleput Collectorate of Madras. They are 2 cubits in breadth, and 28 long and sold at from 2 to 7 Rs. each according to their sizes. They are largely exported to the Straits of Malacca.

(5413) MOORVA, MAROOL. BOW-STRING-HEMP SANSEVIERA ZEYLANICA. Dr. Gibson states grows freely on the Bombay side of India.—*Royle Fib. Plant, p.* 337.

(5414) MOOSLIE. Authors describe the source of this Indian drug, differently.

(5415) MOOSLIE, WHITE. SUFED MOOSLIE. Root of Bombax Malabaricum.—*Beng. Pharm.*

(5416) MOOSLI-SUFAID. ASPARAGUS SARMENTOSUS. The root of the plant is brought from Kotah, and via Pali : considered of a warm nature and given in purges and mesalihs.—*Gen. Med. Top. page* 145.

(5417) MOOSLI-SIYAH, Black root of similar shape and size comes from Kotah ; used in the same way, and considered stimnlant and used as an aphordisiac.—*Genl. Med. Top. p.* 145.

(5418) MOOSLIE, WHITE.

Suffeid Mooslie, DUK. GUZ. & HIND.	Tanneer-Vittang, Kalung, TAM.
	Tsulla Ghedaloo, TEL.

The root of the *Bombax Heptapyllum*. It is long, fleshy, and whitish, and is used as food by the inhabitants of Ceylon, where the plant grows. In Southern, and some parts of Western India, the powdered root is used in the form of a thick mucilage with water, and answers admirably as a nutritious demulcent for convalescent persons. It is also supposed, when taken in this form, to have the effect of filling the small pox, and preventing the confluent disease.—*Faulkner.*

(5419) MOOSLIE, BLACK, NELEPANNY ROOT.

Tal moolie, BENG.	Warahi, Moosalie, SANS.
Kalee Mooslie, DUK. HIND. & GUZ.	Nelepanny kalung, TAM.
Secah Mooslie, PERS.	Nalla tady gudda. TEL.

A tuberous and wrinkled root about four inches long ; it is slightly bitter and mucilaginous to the taste, and is reckoned among those medicines which purify the blood ; it also possesses tonic properties. It is procurable in most bazars throughout India.—*Faulkner.*

(5420) MOOTE KEERAY, TAM. This green Ainslie had never seen, nor did he believe that the Botanical name of the plant had been ascertained. It grows in the Southern parts of the Peninsula, and is eaten by the poor.—*Ainslie, p.* 255.

(5421) MORACEÆ, *Morads*, a natural order of Exogenous Plants which were formerly placed as a sub-order of *Urticaceæ*. The species are trees or shrubs, with a milky juice, sometimes climbing. The leaves are commonly lobed and rough. The flowers are small, monœcious, and collected in heads, spikes, or catkins. The ovules are solitary and suspended. The embryo lies in the midst of fleshy albumen, hooked, with the radicle long, superior, folded down towards the cotyledons. Although the Mulberry and Fig

grow in Europe, all the *Moraceæ* are extra European. The species inhabit the temperate and tropical latitudes of both hemispheres, often forming vast forests. The genus *Ficus* is the most distinguishing feature of this order. Most of the plants of this order furnish caoutchouc. The fruit of the Mulberry is edible, and the leaves of the genus *Morus* are the food of the Silk-Worm. Several species of *Dorstenia* are used in medicine. Other genera of this order yielding useful products are *Broussonetia* and *Maclura*. This order embraces 8 genera and 184 species. —*Eng. Cyc.*

(5422) MOREA CHINENSIS: Thunb.

Belameanda scholarmani. TAM. HORT, MAL.

The root of this plant ground and applied to any part bitten by a Cobra is said by the people of Southern India, to prevent fatal consequences. The leaves are given by the Natives of the Malabar Coast to cattle that have eaten poisonous vegetables, to prevent their dying. See *Hortus Malabaricus*, Part 11th, page 74.—*Ains. Mat. Med. page* 130.

(5423) MOREL.—This species of Fungus is found at the latter end of the rains, and generally dug out of white ants' nests. The wholesome sorts of mushroom are readily distinguished by being of a pink or flesh color in the gills, changing to a darker color as they get older; they have also a peculiar sweet smell: and another criterion of their being edible is the outer skin pealing off easily.—*Jaffrey.*

(5424) MORINA ELEGANS. DIPSACEÆ.—This species is a native of Persia, the colours red, and white, grown from seed as most other annuals.

(5425) MORINDA.

Morinda Citrifolia.

Ali ka Jhar, HIND. | Moagha, TEL.
Aach or Atchy, TAM. | Nyagyee, BURM.

Morinda Umbellata.

Noona marm, TAM.

Morinda Exserta.

Nya, BURM.

Morinda: this name is given to the bark and root of several species of Morinda, the *M. Tinctoria*; *M. Citrifolia*, *M. Umbellata*, in India, and *M. Exserta*, in Burmah, and are employed to form a very valuable red dye, which is fixed with alum; but Buchanan mentions another species the M. ternifolia in Mysore, the root of which is used for similar purposes. Most of the red turbans of Madras are dyed with the root of the Noona tree. The Karens prepare their red dyes most usually from the roots of the morinda tree, and at least two or three species are used for this purpose. The *M. citrifolia*, is cultivated by the Burmese for a dye, but the Karens more commonly use *Morinda exserta* the indigenous species.

(5426) MORINDA BARK. From Morinda tinctoria, citrifolia and umbellatta. Specimens of the bark and root of various species of Morinda were exhibited at the Madras Exhibition of 1855, from different parts of Southern India and the Northern Circars. These form a very valuable red dye which is fixed with alum: colour, though not brilliant, is far more permanent than many other red colours—the most of the Madras red Turbans are dyed with the root bark of the *Noona* tree, which is pretty common, and is in flower great part of the year. The large Triplicane burying ground is thickly studded with the tree. The quantity procurable is very large, and the dye appears worthy of the attention of practical dyers. —*M. E. J. R.*

(5427) MORINDA, MORINDA FRUIT. A species of morinda is often seen growing near Burman houses, which produces a fruit as large as a pullet's egg. It is a great favorite with the Burmese, and is served up in their curries.—*Mason.*

(5428) MORINDA, FRAGRANT MORINDA. The most agreeably fragrant, flowering shrub in the Karen forests, is a species of morinda, that has not yet found its way into cultivation. The flowers are small, in dense heads, like other members of the genus, azure purple externally, but white within; and has only four anthers, like a species described by Jack which he found on the Malay Islands.—*Mason.*

(5429) MORINDA BRACTEATA.

Yaiyoe, BURM.

This wood, of bright yellow colour, is found in the Bengal bazars under the name of *Rouch*, and is valuable as affording a bright yellow dye. The tree is common throughout the province of Pegu. It is also cultivated about Phoungyee houses.—*McClelland.*

(5430) MORINDA, BRACTEATA, YAIYOE: AND M. EXSERTA.

Mhan bin, BURM.

Both are small trees, only found about Phoungyee houses, in a cultivated state: yellow-wood, fit for fancy work.—*McClelland.*

(5431) MORINDA CITRIFOLIA: AAL, ACH, MORINDA CITRIFOLIA. *Rubiaceæ.*

Munja pavuttay marum, TAM. | Togaru kurra, TEL.
Togaree wood, ENG. | Bura-al, HIND.

This tree is common in Kotah and Boondee. The flowers have a very sweet scent and the tree would be ornamental and thrive well in compounds.—*Genl. Med. Top. p.* 182. The wood of this tree is a deep brownish yellow and the roots are used in dyeing. The quality of the wood, judging simply from the appearance, is little if at all inferior to the preceding; but the tree is much smaller.—*Wight.* Mr. Rohde has seen trees of this wood nearly 2 feet in diameter: the roots are used

to assist more expensive dyes in giving a red colour to yarn and cloth—the red thread used in carpet making is entirely dyed with it. The process of dyeing red yarns in the Circars is well described by Heyne.—*Rohde.* The roots of the awal tree of Malabar and other parts of India, *Morinda citrifolia*, and of *M. tinctoria*, found abundant in all the Asiatic islands, are extensively used as a dye stuff for giving a red color. It is usually grown as a prop and shade for the pepper vine and coffee tree. The coloring matter resides principally in the bark of the roots, which are long and slender, and the small pieces are the best, fetching 8s. to 10s. a maund. It is exported in large quantities from Malabar to Guzerat, and the northern parts of Hindostan, but seldom finds its way to Europe.—*Simmonds.*

(5432) MORINDA MULTIFLORA: AAL, VERNACULAR AT NAGAPORE. Achu Al. A native of Berar much cultivated about Nagapore for its dye.—*Rox. Rohde M.S.S.* Cultivated through Rajpootanah principally near Kotah, and all over Harowtee. The plant is allowed to remain three years in the ground, and then the roots are taken up and dried. The dye is a fine turkey red and is very plentiful. One maund costs sixteen rupees. Is not used medicinally.—*Gen. Med. Top p.* 125.

(5433) MORINDA TINCTORIA.

Uchyoota, SANS.	Tagaroo, TEL.
Al or Aach, HIND. BENG.	

This small tree is pretty common in every part of India. It is in flower and fruit the greater part, if not the whole of the year. It is largely cultivated at Boondee, Kotah and Mewar. —*Genl. Med. Top. p.* 182. The bark of the roots is used to dye red, the colour is fixed with alum, but it is neither bright nor durable. In some parts of India, it is cultivated for the sake of the roots. In the Circars the dyers use the bark of the fresh roots bruised and gently boiled in water for a short time. The cloth or yarn is prepared in a cold infusion of the powdered gall of Terminalia chebula, in milk and water; it is then dried and moistened with alum water, and again dried, and receives from the above decoction, a pretty bright, but fugitive red. The green fruits are pickled by the Hindoos and eaten with their curries. The wood is hard and very durable, variegated with red and white, it is employed for gunstocks in preference to all other kinds.—*Roxb. Rohde M.S.S.* Dr. Irvine says the root is extensively exported as a red dye, the colour is fixed with alum. The plant is not allowed to shoot up into the bush, but is dug up the third year after planting. The flowers are very fragrant; of the large plant, the berry is eaten. The wood of all the species is beautiful, hard and durable; and excellent for gun stocks.—*Med. Top. p.* 182.

(5434) MORINDA UMBELLATA. LEAF OF THE UMBELLATED MORINDA. Lin.

Noona marum elley TAM.	Kleeba, SANS.
Chota Al ka paat, DUK.	Mang-kudu, MALAY.

There are two species of this tree common in India, both of which are called Noona Marum by the Tamools, the one however is smaller and more erect than the other, and is distinguished by the botanical appellation of Morinda Umbellata. The roots of either sort are used as a red dye.—*Ains. Mat. Med.* The wood and roots of *M. umbellata*, known in the eastern islands as "Mangkudu," are used extensively for their red dye, in Celebes and Java. Specimens of all these, and of the Lopisip bark, bunchong bulu wood, and the gaju gum (from undescribed plants), have been introduced into England. They are said to furnish excellent dyes in the Asiatic islands. Native dyes from Arracan have also been imported, viz., thit-tel and the-dan yielding red dyes, ting-nget and reros, affording dark purple dyes; and thit-nan-weng, a chocolate dye. These would be worth enquiry, and particulars of the plants yielding them, the quantities available, and the prices might be procured. *Simmonds. Noona-kai*, Tam., the fruit of this tree, when green, is used as pickles.—*Jaffrey.*

(5435) MORINGACEÆ, *Moringads*, a small natural order of Exogenous Plants, embracing the species of the genus *Moringa*. They are characterised by the possession of a many-leaved calyx, perigynous petals and stamens, 1-celled anthers, stipitate and consolidated siliquose fruit, and seeds without albumen. This order is referred by most botanists to a position near *Leguminosæ*, but Lindley places them in his *Violales*. They are natives of the East Indies and Arabia. The root of *Moringa peterygosperma* has a pungent odour with a warm biting and somewhat aromatic taste. The seeds of this plant are called by the French Pois Queinques and Chicot They are the Ben-Nuts of old writers, from which the Oil of Ben was extracted. It is chiefly used by perfumers as the basis of various scents. It does not readily freeze and on this account is used by watchmakers. The flowers, leaves, and other parts of this plant are added to curries in India. —*Eng. Cyc.*

(5436) MORINGA.

Sohunjuna, Moongay kajhar, DUK.	Moriaben, ARAB.
Sujna, HIND.	Seeds Hubool ban, ARAB.
Sigroomala, and Sohanjana, BENG.	Da-tha-lwon, BURM.
Sajna, PERS.	Mooringa marum, TAM.
	Mooraga chettoo, TEL.

Moringa, leaves, root, flowers, seed vessels or fruit, gum, wood, bark, and oil, for all these parts and products of the Moringa pterygosperma are used by the people of India and by Europeans. The tree is very abundant all over India, Burmah and Malay peninsula. The leaves, flowers and seed vessels are used in cur-

ries. The roots have precisely the flavour of horse-radish, and seem identical in chemical composition, and in India are substituted for the true horse-radish by Europeans. The Gum and bark are used in native medicine. Royle mentions that the oil is aperient, and much used by the natives in gout and rheumatism. Ainslie mentions that the native doctors prescribe the green root as a stimulant in paralysis and in intermittents, in scruple doses, and use it also in epilepsy and hysteria. The seeds are also used internally by the native practitioners, for their pungent and stimulating virtues. In Jamaica the wood is used for dyeing a blue colour. An oil is obtained from the seeds possessed of the same qualities as the *oil* of *ben* the product of the *M. aptera*, a native of Sennaar, Cairo and Palestine, much used by perfumers and by watch makers, as it neither grows rancid nor freezes readily. The delicate perfume of flowers are often retained by the ben oil, by pouring it over the flowers, or strewing layers of the flower for about four hours over cotton soaked in the oil. In the West Indies the oil is used as a salad oil. According to Mr Faulkner ben oil is also prepared from the Guilandia Moringa, a tree which he says grows in Ceylon, Arabia, Egypt and Ethiopia.

(5437) MORINGA GUM FROM MORINGA PTERYGOSPERMA, obtained in a large quantity, does not dissolve in water, resembles in some respects Gum Tragacanth, for which it may probably be substituted.—*M. E. J. R.*

(5438) MORINGA APTERA. A native of Sennaar, Cairo, and Palestine. The seed yields the *oil* of *ben*, much used by perfumers and by watch-makers, as it neither grows rancid nor freezes readily; seeds acrid, and used as a rubefacient. They are also said to be purgative and emetic in small quantities.—*O'Shaughnessy, p.* 289.

(5439) MORINGA CONCANENSIS. A new species discovered in the Southern Concan. —*Riddell.*

(5440) MORINGA PTERYGOSPERMA, *Syn.* HYPERANTHERA MORINGA.

Sohunjuna, Moongay ke jar ke-jur, DUK.	Moriaben, PERS.
Sujna, HIND.	Seeds, Hub-ool-ban, ARABIC.
Sigroomala and Sobhanjuna, SANS.	Mooroongay-kai-keeray and poo, TAM.
Sajna, BENG.	Moosing, DUK.

Indian Horse Radish tree.—This tree grows readily from seed, and attains a height of from fifteen to twenty feet, in its second year; the root when young and fresh scraped, has the flavour of English Horse radish; the pods when young and green are used as a vegetable both boiled and in curries; the seed when ripe yields a fine clear oil; the wood of the tree is soft and of little use.—*Riddell.* It is commonly cultivated in India for leaves, flowers, and seed vessels, which are used in curries. The roots have precisely the flavour of horse-radish, and seem identical in chemical composition. Reduced to a pulp they afford an excellent external irritant. An oil is obtained from the seeds, possessed of the same qualities as that of the M. aptera. It is said by Royle to be aperient, and much nsed by the natives as an unguent in gout and rheumatism. The seeds are also used internally by the native practitioners for their pungent and stimulating virtues.—*O'Shaughnessy.* This is a very useful tree. The leaves and flowers are much eaten by the natives, and make an excellent vegetable. The pods are freely eaten by Europeans as asparagus, either boiled separately or in curries—the roots as a substitute for horse radish—the natives have recourse to this root in adulterating the country mustard, prepared here for sale, and very often pass it off for genuine English; cultivated every where, in gardens and about villages. The large branches planted in the ground root freely and soon become small trees, giving a continued supply of wholesome vegetables; produce from seedling plants is the best.—*Jaffrey.* The delicate perfumes of flowers are often retained by the ben oil, by pouring it over the flowers, or strewing layers of the flowers for about four hours over cotton soaked in the oil. It is thus that the jessamine, and several other very volatile odours are obtained by the perfumers. Ainslie mentions that the native doctors prescribe the green root as a stimulant in paralysis, and in intermittents, in scruple doses, and use it also in epilepsy and hysteria. In Jamaica the wood is used for dyeing a blue colour, (Ainslie i. 176). —*O'Shaughnessy, page* 289. The horse-raddish-tree is propagated by the Burmese for its pods, which are eaten in curries; but it is chiefly valued by Europeans for its roots which cannot be distinguished when eaten with roast beef, from the common horse-raddish, *Cochlearia Armoracia.*—*Mason.*

(5441) MORINGA PTERYGOSPERMA, COMPOUND INFUSION OF SOHUNJUNA. This preparation represents the compound infusion of Horse Radish of the London Pharmacopia. The root of the Moringa pterygosperma, Sohunjuna of Bengal, is a perfect substitute in flavour and properties for the European Article.—*Beng. Phar. p.* 304.

(5442) MORINGA PTERYGOSPERMA, COMPOUND SPIRIT OF SOHUNJUNA. Stimulant in a dose of from two to four fluid drachms in water.—*Beng. Phar. p.* 414.

(5443) MORINGA ROOT. SOHUNJUNA. Root of Moringa pterygosperma.—*Beng. Phar.*

(5444) MORINGA SEEDS. HUB-OOL-BAN. Moringæ semina. An excellent substitute for the horse-radish, Cochlearea armoracia.—*Ben. Phar.*

(5445) MOROCCO LEATHER, MAROQUIN.

Maroquin, Fr.	Saffian, Rus.
Saffiam, Ger.	Marroqui, Sp.
Marrocchino, It.	

A fine kind of leather prepared of skins of goats in the Levant, Barbary, Spain, &c. It is of various colours, and is used for lining carriages, chairs, in the binding of books, &c.—*Faulkner.*

(5446) MORUS, a genus of Plants belonging to the natural order *Moraceæ*. The flowers are monœcious; the staminiferous flowers spiked; calyx 4-parted, spreading, membranous; the stamens 4, larger than the calyx, with the rudiments of an ovary between their bases: the pistiliferous flowers clustered; sepals 4, scale-like, imbricating each other, 2 being opposite and external to the other 2; stigmas 2, linear, glandular; ovule solitary, suspended. Fruit consisting of the latter flowers become fleshy and grown together, each inclosing a dry membranous pericarp. Seed pendulous; embryo curved like a horse-shoe, amongst fleshy albumen, with the radicle directed to the hilum. The species are trees.—*Eng. Cyc.* The genus *Morus* is numerous in species and abounding in individuals, many of which are cultivated on account of their fruit, but still more for their leaves as food for the silkworm. It is probable that most of the species of the genus Morus have bark of a sufficiently fibrous nature. But few, if any, seem to be turned to this useful account. Yet the bark of the White Mulberry seems from very early times to have been made into paper in China; for Marco Polo informs us that "the Grand Khan causes the bark to be stripped from those Mulberry trees, the leaves of which are used for feeding silkworms, and takes from it that thin rind which lies between the coarse bark and the wood of the tree. This being steeped, and afterwards pounded in a mortar until reduced to a pulp, is made into paper, resembling that which is made from cotton." This fact directs attention to the bush cultivation of the Mulberry in Bengal, for feeding silk-worms. This culture consists in planting cuttings of the Mulberry, which as they grow, are cut down about four times in the year, in order to produce young leaves for the successive broods of silk-worms. The countless number of shoots which are thus thrown away, or used as fuel, would probably, under the agency of the dhenkee, yield good half-stuff for the paper-maker. Mr. Henley, indeed, informs us that, before leaving India, he had produced very satisfactory specimens of half-stuff from the bark of these rejected stems. The bark separates when the cut stems are steeped in water, and when pounded up, the greater part of the mucilaginous matter passes off, leaving a mass, having much of the good qualities of linen rag half-stuff. —*Royle Fib. Pl. p.* 341. In China, the leaf of the common mulberry is the principal object of its culture, but the fruit is eaten, and the wood burned for lampblack used in making ink—*Williams' Middle Kingdom, p.* 281. Two species, Morus alba, the White, and Morus Nigra, Black, grow equally well in the Dekhan; the white, growing to a very large tree, shedding its leaves before the hot season. The red mulberry bears fruit in the rains, as well as the black. Silk worms may be fed on the young fresh leaves, although the leaves of the white are preferred. Grows from seed or cuttings.—*Riddell.*

(5447) MORUS ALBA, the white Mulberry is a native of China where it forms a small tree, and whence it has been gradually carried westward till it has become a common plant in most of the temperate parts of the Old World, forming in the south of Europe a pollard-tree by road-sides. Its leaves are smooth and shining, usually heart-shaped at the base, and on old trees ovate or oblong, but on young vigorous shoots as frequently divided into deep lobes. The fruit is white, insipid, and of little value except for feeding poultry; in England it is seldom formed. It is on this species that the silk-worm is chiefly fed; and in silk countries many varieties are cultivated for the purpose, some of which are said to be much better than others. The common wild kind is said to suit the silkworm as well as, or even better than, any other kind; but as it yields only a small quantity of foliage, compared with other sorts, it is principally employed as the source of seeds from which stocks are raised for grafting more productive varieties. Of the latter each silk country has its own fancy kinds, which there would be little advantage in noticing here; but there is among them an exception of importance, the value of which has been recognised wherever it has been cultivated. Some years since a mulberry was introduced into France from Manilla, whence it has gained the name of the Philippine Mulberry, the great excellence of which seems universally acknowledged. It has straight smooth branches, oval, heart-shaped leaves, tapering to a point, thin, rather soft, a little blistered and puckered in the middle, often drooping, and sometimes more than six or even nine inches broad in the dry climate of the south of France. It grows much faster than the White Mulberry, and strikes from cuttings as freely as a willow, which is not the case with the latter. The abundance of its leaves is much greater than any other known variety, and, what is most important, it is not only freely eaten by the silkworms, but perfectly agrees with them. Its culture is now superseding that of all others in the south of Europe, and it is even taken as a stock on which to graft the common white Mulberry, when the latter is wished for. According to M. Bonafous this may be done either upon layers of the Philippine Mulberry, headed down to one or two eyes above the ground, or upon cuttings seven or eight inches long, which may be planted immedi-

ately after having been grafted: the young plants will be five or six feet long the first year, and three or four inches in circumference. This mulberry is sometimes called *Morus multicaulis*. In England the White Mulberry and all its varieties suffer a good deal from the winters, but not so much as to prevent its cultivation. Some years ago an attempt was made to introduce it and the rearing of silkworms into Great Britain; but the attempt failed, owing partly to unskilful management, but more to the soft juicy condition of the leaves in that damp climate, which rendered them unfit for the food of the worm. Loudon, *Arboretum Britannicum*).—*Eng. Cyc.*

(5448) MORUS ATROPURPUREA.

Shatoot, Duk.

Cultivated as the former.

This species of mulberry from China scarcely diffused throughout the Tenasserim Provinces, which produces a very agreeable black berry in great quantities and is a valuable fruit.—*Mason.*

(5449) MORUS INDICA, Mulberry. Willd.

Cumble pullum, Tam.	Babisarn, Malay.
Toot, Duk.	Toota, Sans.

A small tree with long tapering leaves sometimes lobed, fruit dark red, used for making tarts.—*Riddell.* This small Indian Mulberry which is found in Southern India, is a delightful fruit and is considered by the natives as cooling and aperient.—*Ainslie, p.* 223,

(5450) MORUS NIGRA. The black or Common Mulberry, is a small tree with very rugged bark. The young shoots are downy; the leaves roundish, cordate, pubescent, coarsely serrated, rough to the touch, slightly acuminate; stipules oblong, membranous, downy, the length of the petiole or longer, deciduous. The Black Mulberry is the only species of *Morus* worthy of being cultivated as a fruit-tree. It is a native of Persia, and its indigenous range appears to be extensive. Its introduction to England dates about the middle of the sixteenth century. Under great vicissitudes it proves very tenacious of life; and under ordinary circumstances it attains, even in that climate, a considerable age, for some trees planted in 1548 are still alive. The fruit is used at the dessert, fresh gathered, and at the same time it ought to be so ripe as to be just ready to drop from the tree; indeed the fruit may be said to be in the highest perfection with regard to ripeness when it actually drops, and hence a grass plot surrounding the trunk is desirable; but the trees are found to thrive better when the soil is kept stirred; however, as grass will be generally preferred, all strong-growing sorts of grasses should be avoided; and it should also be kept very closely mowed till at least immediately before the fruit ripens. By this means the sun's rays will be permitted to penetrate the soil to a greater depth than when obstructed by a covering of long grass. Mulberries are also preserved in the form of a syrup; and their juice, mixed with that of apples, forms a beverage of a deep port-wine colour, called Mulberry-Cider. The soil for mulberrry trees should be of a light, rich, and moderately dry nature. If the subsoil be not naturally pervious, it should be rendered as much so as is possible. A good bottoming of brick rubbish will prove beneficial with regard both to the growth of the tree and the flavour of the fruit. Propagation of the Mulberry may be effected either by seeds, cuttings, or layering. The last is the preferable mode; where it can be conveniently adopted; and the shoots or branches used for this purpose, as also those intended for cuttings, should be selected from those trees, or parts of a tree, that have been observed to be most fruitful; for although the plant is generally monœcious, yet some trees occasionally assume a dicœcious character. Hence, likewise, seedling plants are not so desirable as those propagated from trees previously ascertained to be prolific: and moreover seedling plants are a greater number of years in attaining to a bearing state. As the acquisition of a good mulberry-tree is very desirable, the following directions for obtaining a bearing tree readily and quickly will be useful. If a tolerably large branch of a vigorous tree is ringed and the annulation is inclosed in a box filled with rich soil, sufficiently large to hold as much as will preserve a somewhat uniform temperature, or at least an approximation to that which the roots of a tree naturally experience in the ground, roots will be readily emitted into the earth, and in due time the branch may be cut off and planted. A covering of moss is useful, partly for maintaining an equable temperature, and partly for preserving moisture. The Mulberry-Tree requires very little pruning beyond that of regulating the head. The season for this operation should be always mid-winter; for if in a growing state, this plant bears amputation very ill, especially as regards large limbs. Mulberries have been trained against south walls, over which a single plant has been known to extend upwards of ninety feet horizontally; additional size and flavour are said to have been gained, but certainly not so much over a standard on a proper bottom as to compensate for the great extent of wall-room occupied.—*Eng. Cyc.*

(5451) MORUS PAPYRIFERA, now, BROUSSONETIA PAPYRIFERA. The Japanese make abundance of paper as well for writing and printing, as for tapestry, handkerchiefs, packing cloths for goods, &c. It is of different qualities, and some of it is as soft and flexible as our cotton cloth. Indeed, that used for handkerchiefs might be mistaken for cloth, so far as toughness and flexibility are concerned. The materials, of which it is made is the bark of the mulberry, (morus papyrifera,) and the process is described

as follows: In December; after the tree has shed its leaves; they cut off the branches about three feet in length and tie them up in bundles. They are then boiled in a ley of ashes in a covered kettle, till the bark is so shrunk that half an inch of the wood may be seen projecting at either end of the branch. When they have become cool, the bark is stripped off and soaked in water three or four hours until it becomes soft when the fine black skin is scraped off with a knife. The coarse bark is then separated from the fine; the new branches make the finest paper. The bark is then boiled again in fresh ley, continually stirred with a stick, and fresh water from time to time is added. It is then put in a sieve and taken to a brook, and here the bark is incessantly stirred until it becomes a fine pulp. It is then thrown into water and separates in the form of meal. This is put into a small vessel with a decoction of rice and a species of Hibiscus, and stirred until it has attained a tolerable consistence. It is then poured into a large vessel, from whence it is taken out and put in the form of sheets on mats or layers of grass straw, these sheets are laid one upon another with straw between, and pressed to force the water out. After this they are spread upon boards in the sun, dried, cut, and gathered into bundles for sale. This paper will better endure folding, and last longer than that of Europe.—*American Expedition to Japan page* 64.

(5452) MOSCHIDÆ, a family of Ruminant Quadrupeds familiarly known as Musk-Deer. Linnæus defines the genus *Moschus*, which he places between *Camelus* and *Cervus*, under his order *Pecora*, as having no horns, and the upper canine teeth solitary and exserted—"Cornua nulla Dentes Laniarii Superiores solitarii, exserti." Dr. J. E. Gray, in his 'Disposition of the Mammalia' ('Annals of Phil,' 1825), divides the family *Bovidæ* into two sections, the first with persistent horns, and the second with either no horns or deciduous horns. He makes *Moschina* the fourth sub-family, and arranges it between *Camelina* and *Cervina*, in the second section. The genera of *Moschina*, in this arrangement, are *Moschus* and *Memina*. The same author, in June, 1836, read to the Zoological Society of London some observations 'On the genus *Moschus* of Linnæus, with descriptions of two new species.' He remarked that the only character by which this genus, as established by Linnæus and others, differs from the genus *Cervus*, consists in the absence of horns; for the elongated canines are common to it and most of the Indian species of *Cervus*, especially the *C. Muntjac*. The character of the fur, the degree of hairiness or nakedness of the metatarsus and the presence or absence of the musk-bag of the male, offer however, he observed, good characters for the sub-division of the group into three very distinct sections or sub-genera. The

first of these divisions, for which Dr. Gray would retain the name of *Moschus*, comprehends only the Tibet Musk, *M. Moschiferus*, Linn. In common with the Deer and Antelopes, it has, he pointed out, the hinder and outer side of the metatarsus covered with close erect hair, and, like many of the deer also, its fur is quill-like and brittle; the throat moreover is entirely clothed with hair, and the males are provided on the middle of the abdomen with a large pouch secreting musk. Its young, like those of most of the Deer, are spotted, whilst the adult animal is plain-coloured. Dr. Gray further stated that the division to which, in the year 1821, in a paper in the 'Medical Repository,' he gave the name of *Memina*, also consists of but a single species, the *Moschus Memina*, Linn. In this group the hinder edge of the metatarsus is, he observed, covered with hair; and there is no musk-bag in either sex. The false hoofs, he remarked, are distinct, although Linnæus and Buffon denied their presence. The third and last sub-division is characterised by Dr. Gray, under the name of *Tragulus*, as having the hinder edge of the metatarsus nearly bald and slightly callous, a character which distinguishes them at once from all other Ruminants; the fur is soft, and adpressed like that of *Memina*, but not spotted even when young: the throat is provided with a somewhat naked, concave, sub-glandular, callous disc, placed between the rami of the lower jaw, from which a band extends to the fore part of the chin; and they have no musk-bag. Like all the other species of the Linnæan genus *Moschus*, they have false hoofs; and most of them have the edges of the lower jaw, three diverging bands on the chest, and the under surface of the body, more or less purely white. The species of this division scarcely differ in colour in the various stages of their growth, the young fawn resembling the adult in every particular except in size. In this division, the synonymy of which is stated to be extremely confused, Dr. Gray reckons four species, two of which he describes as new. Dr. Gray stated that he was unable to identify with any of the four species mentioned by him on this occasion, or to separate from them as distinct, the Palendoc, figured in Marsden's 'Sumatra,' or Pygmy Musk of Sumatra, figured in Mr. Griffith's edition of Cuvier's 'Animal Kingdom,' on which Fischer has established his *Moschus Griffithii*. The *M. pygmæus* of Linnæus, in Dr. Gray's opinion, belongs to the genus *Antelope*; the hinder part of the tarsus being covered with hair, and the false hoofs very small and rudimentary, and entirely hidden under the hair of the feet. He thinks that the *M. Americanus* appears by its spotted livery to belong to a species of Deer; and that the *M. delicatulus*, or Leverian Musk of Shaw, is undoubtedly the fawn of a deer. Dr. Gray further observed that it is curious that Dr. Shaw quotes as

a synonym of the last-named species the figure of Seba, on which alone the *M. Americanus* is founded, while at the same time he enumerates the *M. Americanus* as a distinct species ('Zool. Proc.,' 1836.) In the same year Mr. Ogilby, in his paper on the 'Ruminantia,' read before the Zoological Society, makes the *Moschidæ* the third family of that order, with the following character :—Feet bisulcate; horns; incisor teeth (primores), above none, beneath eight. Two genera,

1. *Moschus*.—Rhinaria large. Lachrymal sinuses none; interdigital fossæ none; inguinal follicles none: teats four. Type *M. Moschiferus*.

2. *Ixalus* (?).—Rhinaria none. Lachrymal sinuses small and distinct; interdigital fossæ none; inguinal follicles small; teats two. Type, *I. Probaton*. ('Zool. Proc.,' part iv. p. 119.) Mr. Ogilby goes on to state that the genus *Ixalus*, founded upon the observation of a single specimen, may eventually prove to belong to a different family: and indeed he observes that it differs little from the true antelopes; but even supposing it to be correctly placed among the *Moschidæ*, other forms, Mr. Ogilby remarks, are still wanting to fill up the chasms which evidently exist among the character of that group. "Two," continues Mr. Ogilby, "are more especially indicated, and our knowledge of the laws of organic combination, and of the constituent parts of other groups, gives us every reason to believe in their actual existence, and to anticipate their discovery." He then proceeds to characterise the genera *Hinnulus* and *Capreolus*, observing that they will probably be found, one in the tropical forests of the Indian Archipelago, and the other on the elevated table-lands of Mexico or South America. "It may appear a bold, perhaps a presumptuous undertaking," says Mr. Ogilby, "thus to predict the discovery of species and define the characters of genera, of whose actual existence we have no positive knowledge; but, as already remarked, all the analogies of nature, whether derived from organic combination, or from the constituent members of similar groups, are in favour of the supposition; and I may observe further, that the recent discovery of the genus *Ixalus*, if indeed it eventually prove to be a genus, of which I had long previously defined the characters, as I have here done for the presumed genera *Hinnulus* and *Capreolus*, strengthens my belief in the actual existence of these forms, and increases the probability of their future discovery." The family is placed by Mr. Ogilby between the *Cervidæ* and *Capridæ*. The same author makes *Tragulus* (type *Antilope pygmæa*) the first genus of his family *Bovidæ*. The *Moschidæ* do not differ much from the other Ruminants: the leading differences are given above, and the general osseous structure of the form may be collected from the following.

Dental Formula:—Incisors, $\frac{0}{8}$; Canines, $\frac{1-1}{0-0}$; Molars, $\frac{6-6}{6-6}$ = 34.

The canine teeth go far back into the upper jaw. It is not impossible that the so called canine teeth of *Ursus cultridens* may be the canine teeth of an extinct ruminant allied to this family, or that of the *Cervidæ*.

Moschus Moschiferus, the Musk, or Tibet Musk. It has somewhat of the form of a Roebuck; but higher behind than it is at the shoulder, from the upper part of which to the sole of the foot it measures about 2 feet 3 inches; whilst from the top of the haunches to the soles of the hind feet the measurement is about 2 feet 9 inches. Ears long and rather narrow, in the inside pale-yellow and dark-brown outside. Hair on the body suberect, long, each hair marked with short waves from top to bottom, ash-coloured near the base, black or blackish near the end, and rusty at the tips. Chin yellow. The colours vary. Most of the adults are plain-coloured. In some, and such is the individual figured by Pennant, the fore part of the neck is marked on each side with long white stripes from the head to the chest, the back striped transversely with pale-brown reaching to the sides, which are also dappled with a lighter colour. Hoofs very long and deeply divided, spurious hoofs very long. Tail about an inch long, concealed in the hair. Scrotum rutilum. Penis vix percipiendus. (Pennant.) Female less than the male, and wants the two tusks. Young, spotted. The Musk is a mountain animal, timid, and shy, and lover of solitude. Precipices covered with pines and almost inaccessible crags are its favourite haunts; and the musk-hunter often perils his life in the dangerous chase; for when hotly pursued the animal takes refuge frequently in the highest fastnesses, leaving men and dogs with scarcely the possibility of access to the precipitous summits to which it flies. And yet the slaughter made among them must at one time have been great, and the animals abundant; for Tavernier bought in one journey 7673 musk-bags. The bag, or tumor, containing this well-known drug is peculiar to the male: it is kidney-shaped, pendulous, of the size of a hen's egg, and situated beneath the abdomen. There are said to be two apertures, the larger oblong, the smaller round, and covered with hair: and on the application of pressure the musk may be forced through the apertures. It is brown and unctuous. This bag the hunters cut off, and tie it up for sale, but, like everything that is calculated for the use of man and is the object of commerce, it is said to be adulterated by the admixture of foreign matter, and pieces of lead are stated to have been found enveloped in it, for the purposes of increasing the weight. The musk which comes from Tibet is considered the best, and used to bear the highest price; the bag is more or less full, and the quality more or less good, according to the age and health of the animal. When dry, musk is dark-brown, inclining

to red, or rusty-black, and appears more or less granulated. To the taste it is rather bitter and somewhat acrid. It is perhaps the strongest and most pungent of perfumes, and so subtle that every thing near it becomes infected, and for a long time retains the odour; vessels of silver even, a metal which, as much as, if not more than others, readily becomes purified from odorous substances, do not part with the scent of musk, which may have been placed in them, for a long time. When fresh, or exposed in large quantities, its effects upon the nervous system are said to be absolutely violent; and it is stated that blood has been forced from the nose, eyes, and ears, of those who have imprudently inhaled the vapour of a considerable quantity. When Chardin made his purchases, he secured himself from the sudden effects of the smell by covering his face with a handkerchief several times folded. The mere skin of the animal fills the place where it is kept with the perfume for a long period. In medicine it is used for nervous and convulsive cases in considerable doses. The flesh of the animals, though that of the males is rather highly flavoured with musk, is eaten by the Russians and Tartars. In rutting-time this flavour is most predominant. It is a native of Tibet; the province of Mohang Meng in China; Tonquin, and Hootan; about the lake Baikal; and near the rivers Yenesei and Argun. Found from lat. 60° to 44° or 45°; but never wanders so far south, except when forced through hunger, by great falls of snow, when it migrates to feed on corn and new grown rice. (Pennant.) The description given by Linnæus of this species is an example of his great neatness. He describes the Tibet Musk as *Moschus folliculo-umbilicali;* and this is the distinction of the species, as far as we yet know. It does not appear to have been known to the ancients, but seems to have been first mentioned by the Arabians. Serapion described it in the 8th century. There are three other species of *Moschus—M. Sibiricus*, the Kubaya, a native of Siberia; *M. leucogaster*, the White-Bellied Musk, a native of Nepaul; *M. chrysogaster*, the Golden-Eyed Musk, also from Nepaul. The *Moschus aquaticus*, Ogilby, the Boomorah of West Africa, is the *Hyemoschus aquaticus* of Gray.

Meminna Indica (*Moschus Meminna*, Linn.) It is the only species known. Length about 17 inches. Ashy-olive; throat, breast, and belly white, sides and haunches spotted and barred transversely with white: ears large and open, tail very short. Weight about 5½ lbs. It is a native of Ceylon and Java. (Pennant.) Colonel Sykes informs us that it is the Peesoreh of the Mahrattas, and that it is found in considerable numbers in the dense woods of the Western Ghauts, but never on the plains. ('Zool. Proc,' 1831.) Pennant described it from a drawing communicated by Governor Loten, of Ceylon.

Tragulus Javanicus, Pallas (*Moschus Javanicus*, Gmelin and Raffles; *M. Napu*, F. Cuvier), is the size of a large hare. Body heavy. Limbs very delicate. Head arched and long. Eyes large but not expressive. General colour brown mixed with blackish-gray or yellow reflections; yellow predominating along the back and tail, on the legs, the neck, and head; the gray and black prevail on the lower part of the shoulders, on the sides, and thighs. These different tints are the result of the colouring of the hairs, which on those parts which are yellow are of that colour for the greatest part of their length and black at the point, and where the hairs lie very thick and one on the other, some of the parts appear black. Lower jaw white; two white lines which spring from it extend thence beyond the cheeks; two other white bands spring from the same point as the first, and terminate at the shoulders; a middle band descends on the breast, widening in its descent, and is lost in the white of that part. The upper edge of the first two white bands is bordered with black, and the other bands are all separated from each other by hairs of a brownish-black colour. Belly, anterior and upper part of the hind legs, posterior and upper part of the fore legs, and the under part of the tail, white. End of the muzzle naked. Eyes surrounded with a naked part, from which springs a band without hairs which goes to the muzzle. These naked parts are black with a slight tint inclining to violet. The toes are united, by a rather loose membrane, nearly to the origin of the hoofs, which are very long and pointed; the spurious hoofs are also long, cylindrical, and pointed. Length about 24 inches. Height to the shoulder rather more than 9 inches, to the top of the haunches rather more than a foot. Mr. Bennett observes that M. F. Cuvier regards five radiating bands as the distinctive character of the Napu, and three as that of the Kanchil; whereas, in truth, the number is the same in both, and the difference is only in their disposition. The Napu comes from Java and Sumatra. Sir Stamford Raffles states that this species frequents thickets near the sea-shore and feeds principally upon the berries of a species of *Ardisia*. He adds that it can be easily trained, when taken young, and will become quite familiar. Dr. Gray refers also to this genus *Moschus Kanchil* (Javan Musk of Shaw, Le Chevrotain de Java of Buffon); *M. fulviventer* (Le jeune Chevratain of Buffon); and *M. Stanleyanus*, of which last, in 1836, there were four living specimens in the magnificent collection of the Earl of Derby at Knowsley; and two others consisting of a specimen of each of the varieties, in that of the Zoological Society of London, the gift of her present Majesty. With the exception of the last, whose locality is not known, these

are Oriental, the Kanchil being an inhabitant of Java, and the *Tragulus fulviventer* a native of the Malacca Islands and the East Indian Peninsula, but the habitat of *T. fulviventer* is given by Dr. Gray with a query.

(5453) MOSQUITO, a term applied to certain stinging Flies belonging in all probability to several distinct genera. The mosquitoes are either gnats or gnat-like insects, which are furnished with a proboscis adapted for piercing the flesh, and at the same time forming a kind of siphon through which the blood flows; this instrument moreover injects into the wound which it makes a poison which causes inflammation. Many insects called Mosquitoes probably belong to the same tribe as the Common Gnat (*Culex*, Linn.); Humboldt however asserts that the insects known by that name in America belong to the genus *Simulium*, and that the *Culices*, which are equally numerous and annoying, are called Zancudoes, which means long legs. The former are what the French call Moustiques, and the latter Cousins.—*Eng. Cyc.*

On the Metamorphoses of the Musquito—*By* W. GILCHRIST Esq., *of the Madras Medical Establishment.*—The Musquito has three stages of existence, in two of which it is a water insect, in the third the well known winged one—6th May, 6 A. M. I observed several Musquitos on the surface of some stagnant water, each in close proximity to a yellowish substance, which, when viewed through a microscope, proved to be a collection of eggs that the musquitos were depositing; each collection, though consisting of not fewer than one hundred eggs, did not exceed three twentieths of an inch in length, and about one twentieth of an inch in breadth. These eggs were arranged in lines, standing on end, and were each about 1-40th of an inch long; the lower end being larger than the upper, so that the upper surface of the collection was somewhat concave. A few of these collections of ova were carefully introduced, with some of the water on which they floated, into a tumbler, and placed under a glass shade. Excepting a change of colour, from a yellow to a dark brownish grey, which occurred within six hours after being put into the tumbler, no visible alteration took place, till two days and a half, when the water was found to swarm with animalculæ. The shells of the ova were still adherent, as when first observed. On examining one minutely, the larger, or under, end was found to have opened, like a lid, to allow the insect to escape into the water. A lady's thimble, furnished with a lid, would resemble exactly the appearance of what is being described. The design of having the lids placed at the bottom, is, evidently, to allow the newly hatched animalculæ immediate exit from the shell into the water; and the concavity of the whole collection, above alluded to, effectually tends to retain the large ends undermost. Had the ova been arranged promiscuously, as to the large and small ends being upwards and downwards, it is evident that the newly hatched insect, under the former arrangement, would have some difficulty in reaching the water, a difficulty that, most probably, would amount to an impossibility; one which, at all events, is effectually prevented by the concave form of the collection. A sketch of the newly hatched insect, about 2,500 times the natural size, was given in figure 1. In the chest, or thorax (*a*), the heart is seen (obscurely however, the body being only semi-transparent), furnished with four projections; from this organ two blood-vessels proceed down the centre of the body, to the end of the elongation (*b*), the extreme termination of which is to be seen just above the surface of the water, where the insect lives, for the most part; the body being suspended, as it were, from this, head lowermost. Between the heart, in the thorax, and the extremity of this singular elongation, an active sanguiferous circulation is to be observed; in all probability, therefore, it is the seat of the lungs or gills, and it would appear, that a comparatively large supply of air, is essential to the existence of the insect, as it lives, as much as possible, in this pendulous position at the surface, with the extremity of the elongation rising just above. Its motion, which is quick, is effected by a rapid bending of its whole body, so that head and tail (the latter represented at (*c*), and consisting of a bundle of delicate filaments, approximate, alternately, on either side of the body; it always goes tail foremost, so that the head is dragged along behind. When in search of food, it throws out, in advance of its mouth, a couple of delicate brushes, the individual filaments of which, though seen magnified to the extent above stated, were still of microscopic size. The oval shaped figures in the head (*d*. fig. 1.) represents these brushes when not in use (though obscurely, as the semi transparent body intervenes) Each of these is put in rapid circular motion, w[illegible] double kind of whirlpool is occasione[illegible]omen. The[illegible]od comes within the sphere of the[illegible] larger obl[illegible]eedily devoured. The food appear[illegible]ed with hair: ly, decomposing vegetable matte[illegible]sure the musk I put into the tumbler, as the[illegible]rtures. It is br[illegible]e ova were discovered contain[illegible]g the hunters cu[illegible]y fed voraciously. They did[illegible]ut, like everyth[illegible] entirely confine themselves to[illegible]e use of ma[illegible]iet. I was much amused with o[illegible]ce, it is said, in a drop of water under the microscope of for[illegible] these confined limits its appetite did not f[illegible]sfie it, and the only article of food it found, was the head of one of its own species. So soon as this came within the vortex, it was ravenously seized, but, being apparently, too large a *morceau*, it was let go, after sundry futile attempts at swallowing. It frequently came within the whirlpool again, and was as

often seized, but with no better success. They, however, eat the shells they had recently quitted. Some that were kept in clean water, without food, died on the third day. In this stage of their existence, the insects were lively and grew apace. At the termination of 21 days, during which the water was thrice changed, they had attained three or four twentieths of an inch in length. On attaining this size, or age, they underwent a second metamorphosis. The shape they assumed is represented in fignre 2, magnified, like the former, 2,500 times. Most likely they cast their former envelope, for the hairs, so conspicuous on the former insect, were not to be seen on the present. The shape, it will be remarked, has materially altered, but the most remarkable change is that which occurs with respect to the seat of the lungs, or gills. These organs are now situate in the thorax, their former seat (the elongation b. fig. 1) has disappeared, and the channel of communication, now, between them and the air, are two small tubes (b. fig. 2) on the top of the chest. In this stage of their existence, the insects are much less active than during the former one. A still greater contrast, however, is that, now, they do not require food, and have no mouth; in this respect resembling the charysalis stage of the butterfly tribe. But the demand for air appears increased; they rarely leave the surface of the water, and, when they do descend, they take down a supply of air, small globules of which are distinctly to be observed, at the end of the tube (b. fig. 2). Their descent is accomplished by striking the water with their body, but, being specifically lighter than that fluid, they rise without any effort to the surface, though, in case of *despatch*, can impel themselves upwards by the same means as they descended. However, as has been remarked, they seldom leave the surface, and, having done so, speedily return to it. The insects remain about 48 hours in this stage; towards the termination of which the legs and proboscis of the winged musquito can be distinctly seen through the thin membrane that surrounds it. This, in due course, bursts, when the winged musquito draws itselt out, stands on the surface of the water a few minutes, to dry and expand its wings, on which it presently proceeds to a dry situation. I observed several undergoing this change. If the musquito, when in either of the first two stages, be taken out of the water, it speedily dies, and it is as speedily deprived of life, if immersed in that fluid immediately after becoming the winged insect. We learn, from the above, that the musquito is a most prolific insect and that, as stagnant water such as that of tanks, &c. is necessary to its propagation, all such ought to be kept as distant as possible from our dwellings; thereby we are more likely to enjoy an immunity from their annoyance, than by practising the mode so facetiously described, or rather suggested, by Captain Basil Hall in his voyages.—*Gilchrist M. L. S. J. July* 1836.

(5454) MOTACILLINÆ, OR MOTACILLIDÆ, a sub-family of Birds belonging to the family *Sylviadæ*. [SYLVIADÆ.] They are an active graceful race, tripping it along the smooth shaven grassplots, edges of ponds, and sandy river-shores in unwearied search for their insect-food, and with tails which never cease to vibrate as long as their restless bodies are in action. The species are natives of the old World only—Europe; Asia, and Africa. At least the form does not appear to have been hitherto detected in America, and that continent has now been much searched by zoologists.—*Eng. Cyc.*

(5455) MOTHER OF PEARL SHELL, OYSTER SHELL.

Cheep, GUZ. HIND. & PERS.

Is extensively used for inlaid work, toys, snuff-boxes, buttons, &c. Mother of pearl Shells are imported in Bombay from the Persain Gulf, and are re-exported to England and France.—*Faulkner.* Mother-o-pearl shells are brought to the Chinese market from the islands of the Pacific and Sulu sea, in the same vessels which bring bicho-de-mar; it also comes from California. It is a small trade, and not likely to increase much. A large proportion of that which is brought to China is re-exported in the shape of fans, paper-knives, card-cases, fish counter, and a great variety of fancy articles, the structure of the nacre of the shell rendering it easy to carve and emboss. Large shells are the best, and these should be chosen of which the nacre or inner surface is not decayed or fractured.—*Morrison.*

(5456) MOTHER-OF-PEARL, or NACRE, is the hard, silvery, internal layer of several kinds of shells, especially oysters, the large varieties of which in the Indian seas secrete this coat of sufficient thickness to render the shell an object of manufacture. The genus of shell-fish, *Pentadinæ*, furnishes the finest pearls as well as mother-of-pearl: it is found round the coasts of Ceylon, near Ormus in the Persian Gulf, at Cape Comorin, and in some of the Australian seas. The dealers in pearl-shells consider the Chinese from Manilla to be the best: they are fine, large, and very brilliant, with yellow edges. Fine large shells of a dead white are supplied by Singapore. Common varieties come from Bombay and Valparaiso, from the latter place with jet black edges. South Sea pearl-shells are common, with white edges. The beautiful dark green pearl-shells called *ear-shells* or *sea-ears* are more concave than the others, and have small holes round the margin; they are the coverings of the *Haliotis*, which occurs in the Californian, South African, and East Indian Seas. In the Indian collection of the Great Exhibition, specimens of the finest pearl-

shells were shown, such as the *Meleagrina margaritifera*, *Haliotis gigas*, *Haliotis iris*, and a large species of *Turbo*, which shells are known in commerce as *flat-shells*, *ear shells*, *green snail-shells*, *buffalo-shells*, *Bombay shells*. Messrs. Fauntleroy and Mr. Banks had also some fine collections. The latter gentleman states that the shores of the Sooloo Islands afford the finest shells. The beautiful tints of mother-of-pearl depend upon its structure; the surface being covered with a multitude of minute grooves, which decompose the reflected light. Sir David Brewster, who was the first to explain these chromatic effects, discovered, on examining the surface of mother-of-pearl with a microscope, "a grooved structure, like the delicate texture of the skin at the top of an infant's finger, or like the section of the annual growths of wood as seen upon a dressed plank of fir. These may sometimes be seen by the naked eye; but they are often so minute that 3,000 of them are contained in an inch." It is remarkable that these iridescent hues can be communicated to other surface as a seal imparts its impress to wax. The colours may be best seen by taking an impression of the mother-of-pearl in black wax; but "a solution of gum arabic or of isinglass, when allowed to indurate upon a surface of mother-of pearl, takes a most perfect impression from it, and exhibits all the communicable colours in the finest manner, when seen either by reflection or transmission. By placing the isinglass between two finely-polished surfaces of good specimens of mother of-pearl, we obtain a film of artificial mother-of-pearl, which, when seen by single lights, such as that of a candle, or by an aperture in the window, will shine with the brightest hues." [Brewster's Optics, Chapter XIV., one of the volumes of the Cabinet Cyclopœdia.] It is in consequence of this lammellar structure that pearl-shells admit of being split into laminæ for the handles of knives, for counters, and for inlaying. Splitting, however, is liable to spoil the shell, and is therefore avoided as much as possible. The different parts of the shell are selected as nearly as possible to suit the required purposes, and the excess of thickness is got rid of at the grindstone. In preparing the rough pearl-shell, the square and angular pieces are cut out with the ordinary brass-back saw, and the circular pieces, such as those for buttons, with the annular or crown-saw, fixed upon a lathe-mandrel. The pieces are next ground flat upon a wet grindstone, the edge of which is turned with a number of grooves, the ridges of which are less liable to be clogged than the entire surface, and hence grind more quickly. If the stone be wetted with soap and water it is less liable to be clogged. The pieces are finished on the flat side of the stone, and are then ready for inlaying, engraving, polishing, &c. Cylindrical pieces are cut out of the thick part of the shell, near the hinge, and are rounded on the grindstone preparatory to being turned in the lathe. The finishing and polishing are described in the third volume of Mr. Holtzapffel's excellent work on Mechanical Manipulation." Counters, silk-winders &c., are smoothed with Trent sand or pumice-stone and water on a buff-wheel or hand-polisher, and are finished with rotten stone moistened with sulphuric acid, which develops finely the striated structure of the shell. For inlaid works the surface is made flat by filing and scraping; then pumice-stone is used, and after this putty-powder, both on buff-sticks with water; and the fine polish is given with rotten stone and sulphuric acid, unless tortoise-shell or some other substance liable to be injuriously affected by the acid be present in the inlay. In turned works fine emery-paper, rotten-stone and acid or oil are used. The pearl handles for razors are slightly riveted together in pairs, then *scraped*, *sand buffed* on the wheel with Trent sand and water; thirdly, *gloss-buffed* on the wheel with rotten stone and oil, or sometimes with dry chalk rubbed on the same wheel; and fourthly, they are *handed up*, or polished with dry rotten-stone and the naked hand.—*Tomlinson.*

(5457) MOTHER-WATER, the liquor left after a saline solution has been evaporated so as to deposit crystals on cooling.—*Faulkner.*

(5458) MOTHRUS. Gums and Gum Resins. Let-pau, Bur.

Bombax pentandra, and *Bombax heterophylla*, are two common trees found in every part of the Pegu Forests which yield an astringent gum resin, called in the bazars of Bengal *Mothrus*. I have not been able to learn whether the Burmese extract this gum, but from the abundance of trees affording it, it might become an article of some importance.—*McClelland.*

(5459) MOTHS. At Lemu Samdong in the Lachen valley *Noctuæ* and *Geometræ* abounded, with many flies and Tipulæ. *Hymenoptera* were scarce, except a yellow *Ophion*, which lays its eggs in the caterpillars above-mentioned.—*Hooker, Vol.* II. *p.* 65.

(5460) MOW CHOK. Bambusa, species. The most beautiful bamboo in the world—was growing about in wild profusion. This bamboo I have never met in any other part of the world. In the central and eastern provinces [redacted] China it is largely cultivated, [redacted] sides of mountains where [redacted] and in the vicinity of [redacted] monastic buildings. Its stems [redacted] n, and clean, the joints are [redacted] small, [redacted] the height of from sixty to eighty [redacted] or thirty feet of the lower part of its stem are generally free from branches. These are produced on the upper portion of the tree, and then they are so light and feathery

that they do not affect the cleanness of the main stem. In addition, therefore, to the highly picturesque effect it produces upon the landscape, it is of great value in the arts, owing to the smoothness and fineness of its structure. It is used in the making of sieves for the manipulation of tea, rolling tables for the same purpose, baskets of all kinds, ornamental inland works, and for hundreds of other purposes, for which the bamboo found in India is wholly unsuitable. Like all other species of the same tribe, it grows with great rapidity and perfects its growth in a few months. To use a common expression, "one could almost see it growing." I was in the habit of measuring the daily growth in the Chinese woods, and found that a healthy plant generally grows about two feet or two feet and a half in the twenty-four hours, and the greatest rate of growth was during the night. The young shoots just as they peep out of the ground are highly esteemed as food, and are taken to the markets in large quantities. I was in the habit of using them as a vegetable every day during the season, and latterly was as fond of them as the Chinese are themselves. Sometimes I had them split up, boiled, and dished by themselves, at other times they were used in soup, like cabbage; and in one occasion Mr. Forbes the American Consul in China, to whom I recommended them, taught me to make an excellent omelette, in which they form one of the ingredients. In the South of China, that is about Hong-Kong and Canton, several kinds of the bamboo are very common. There is a yellow variety with beautiful green stripes, painted on its stems as if done by the hand of a most delicate artist. But all these kinds resemble the Indian varieties,—that is, they grow in dense bushes, their stems are not remarkable for their straightness, and the large joints and branches which are produced on all parts of the stem, give it a rough surface, and consequently render it unsuitable for fine work. These tropical, jungly-looking bamboos disappear as we go to the more northern latitudes and in their places we have the mow-chok, already mentioned, the long-sin-chok, the hoo-chok and one or two others, all with clean stems and feather-branches, suited for the most delicate kinds of work, and all "good for food." These trees are well worth the attention of people who inhabit temperate climates, such as the south of France Italy, and other parts of the south of Europe. No doubt they would be well [illegible] to some parts of Australia, [illegible] southern portions of the Un[illegible]rica. In the province of Ch[illegible] summer heat is from 90° to [illegible] but only a few days in the [illegible] August so high; in winte[illegible] (Fahr.) is rarely so low as 20. Those interested in this matter may consult my 'Wanderings in China,' and 'Journey to the Tea Countries,' for fuller accounts of the climate of this part of the China. With regard to soil and situation, it should be remarked that these trees invariably grow in a rich yellow loam on the slopes of the hills. I have succeeded in introducing the mow-chok to India, and at no very distant day it may be seen flourishing on the slopes of the Himalaya in the north-western provinces, where the bamboos are very inferior. Several plants were also sent to the Agricultural and Horticultural Society of India, and reached Calcutta in good condition—*Fortunes' Residence in China, page* 189.

(5461) MOWTAN OR TREE PŒONY, is abundant in China, fruits large and variegated flowers, it bears the name of hwawang, or king of flowers to indicate the estimation in which it is held. The skill of the native gardeners has made many varieties, but the difficulty of perpetuating them may be one reason for their high price.—*Williams' Middle Kingdom, p.* 285. Tree pœonies are not natives of the South of China, but are brought down in large quantities every year, about the month of January, from the northern provinces. They flower soon after they arrive, and are rapidly bought up by the Chinese to ornament their houses, after which they are thrown away, as they do not thrive well so far south as Canton or Macao, and will not flower a second season. They are sold according to the number of flower-buds they may have upon them and many of them fetching rather high prices.--*Fortunes' Wandering, p.*154. A flower painter inChusan had informed me that several very valuable varieties of the Moutan, or tree Pœony, were to be found in Gardens near Shanghae. Those varieties of this flower, which are yearly brought from the northern provinces to Canton, and which are now common in Europe, have blossoms, which are either rose-colored or white: but it was always asserted, although not believed, that in some part of China purple, blue, and yellow varieties were produced, although these were never brought to Canton for sale. It was for these that I made the most particular inquiries, and this painter not only affirmed he had seen them, but also offered, for a small sum, to make me drawings from memory of all the different kinds. I employed him at once, and when he had finished the drawings, I took them with me to Shanghae. A nursery-man, who had a flower-shop in the town, to whom I showed these drawings, promised at once to procure living plants for me, but said they would [illegible] very expensive, as he would have [illegible] send to [illegible]o-chow, a distance of nearly one hundred [illegible]s, for they were not to be procured in the [illegible]cinity of Shanghae and a man would be about at least eight days. I was, of course, glad to get them upon any terms, and gave the man the price he asked which, after all, was not much out of the way, if they were to be brought a hundred miles. At the specified time the Mou-

tans arrived and proved most valuable kinds, which, in England would have brought a very high sum. Amongst them there were lilacs and purples; some nearly black; and one which the Chinese called, "the yellow" which, however, was only white with a slight tinge of yellow near the centre of the petals.—*Fortunes' Wanderings, page* 135.

(5462) MOWA OIL.—Bassiæ Oleum.—Oil of Bassia latifolia.

(5463) MOZAIC GOLD. Bronze Powder.

A bisulphuret of tin, formed by heating the peroxide with its weight in sulphur. It is produced in small, soft, shining flakes, of a golden yellow colour. It is chiefly imported into England from Germany, and is much used for ornamental work, particularly paper hangings.—*Waterston. Faulkner.*

(5464) MUCIC ACID, See Gum.

(5465) MUCILAGINOUS SEEDS &c. OF INDIA.

Linseed, (Ulsee,) Linum Usitatissimum,
Quince, (Beh Dana,) Cydonia vulgaris,
Tookhm,(Bulungo,) D. racocephalum Royleanum.
Isufghol, Isufghola, Plantago, Dr. Taylor.

(5466) MUCUNA, a genus of Plants belonging to the natural order *Leguminosæ*. The calyx is campanulate bilabiate with two very caducous bracteoles as long as the tube; the upper lip broad, entire, and obtuse; the lower lip trifid, with acute segments. The corolla is papilionaceous, with a cordate vexillum incumbent on the wings, much shorter than the wings and the keel, and without callosites. The stamens are diadelphous, with five of the anthers oblong, linear, and the other five ovate and hairy. The seeds oval, roundish, or reniform, with a narrow, oblong, or linear hilum. The species are climbing herbs or shrubs, with pinnately-trifoliate leaves and axillary racemes, which hang down when bearing fruit.—*Eng. Cyc.*

(5467) MUCUNA PRURIENS. *Syn.* Dolichos pruriens. Lin.

Poonaykali, Tam.	Nai Carana, (Hort Mal), Cowitch.
Kanchkoori ke beenge, Duk.	Copikachu, Atmagupta Sans.
Peelia dooghookaia, Tel.	
Kiwach, Hind.	

This when cleared of the small hairs which cover it is eaten by the Natives like other beans. Rheede says that on the Malabar coast it is supposed to have the effect of exciting venery.—*O'Shaughnessy, Ainslie, p.* 244. *M. pruriens*, Common or Stinging Cowitch, has entire ovate-acute leaflets, smooth above, hairy beneath, the lateral ones oblique at the base, the middle one slightly rhomboidal. The racemes are from 12 to 18 inches long, lax, and many-flowered. The calyx is hairy, pink, with narrow lanceolate segments. The flowers have a disagreeable alliaceous smell; the vexillum is flesh-coloured, the wings purple or violet, and the keel greenish-white. The legumes about 3 inches long, the thickness of the finger, closely covered with strong brown stinging hairs. The seeds oblong, variegated with a white hilum. A mixture of the hairs of this and the next species form the Cowitch of commerce. The ripe pods are dipped in syrup, which is scraped off with a knife, and when the syrup has attained the thickness of honey, by means of the hairs becoming mixed with it, it is used as a medicine, and is considered a good anthelmintic, as it occasions no uneasiness. It is given from a tea-spoonful to a table-spoonful in the morning, fasting. The hairs, when applied to the skin, produce an intolerable and painful itching. A vinous infusion of the pods, 12 to a quart, is said to be a certain remedy for dropsy. A strong infusion of the roots, sweetened with honey, is used by the native practitioners in India in cases of cholera. It is likewise considered a powerful diuretic.—*Eng. Cyc.* The strigose hairs of the plant called *kiwach* in India, as well as those of *Rottlera tinctoria*, are used in India as an Anthelmintic, whence the practice was probably introduced as well as its corrupted name. Sir. W. Hooker has distinguished the East India plant, *M. prurita* from M. *pruriens*, which is indigenous in the West Indies. The pods of the Kiwach, when young and tender, form articles of diet in India. When ripe, they are of a brownish colour, and covered with innumerable sharp prickle-like hairs, which penetrate into and irritate the skin. *Action. Uses.* Mechanical, Anthelmintic. Useful in expelling lumbrici and ascarides, by sticking into their bodies, when pressed against the intestinal, and thus irritating and dislodging them. *D.* The pod being dipped into treacle or honey, have the hairs scraped off until they have the consistency of an electuary when a table-spoonful may be given to adults, and a tea-spoonful to children, followed by a purgative of Castor Oil, &c.—*Royle.* The cowhage, or cow-itch, with its stinging pods is very common in the Karen jungles. Mr. Mason thinks it is the common species, but he never met with the plant in flower. —*Mason.*

(5468) MUCUNA PRURITA, Cowitch, has purple flowers in compact ovate racemes; leaflets hairy beneath, the middle one rhomboidal and obtuse, the lateral ones dilated on the outer edge; the legumes are oblong, curved, compressed, not keeled, and covered all over with a thick coating of short stinging hairs, which turn black in drying and brown when ripe. It is a native of the hedges and banks of the East Indies.—*Eng. Cyc.*

(5469) MUDAR. Yercum nar, or Mudar or Ak, are names applied to the fibres of the *Calotropis gigantea*, the gigantic swallow, wort, also to the C. Hamiltonii, a plant which is widely diffused throughout the southern provinces of the penin-

sula of India where it grows wild, preferring poor soil near the sea. It is replaced in the Bellary district, C. by procera, which is equally common and in Northern India by C. Hamiltonii.

(5470) MUDAR BARK. Arund. Bark of root of Calotropis gigantea.—*Beng. Phar.*

(5471) MUDUD, pills of the size of a pepper corn, made of chopped betel leaf and opium: and smoked in a small chillum.—*Herklots.*

(5472) MUEDA LUKREE. Wood of Tetranthera Roxburghii.—*Beng. Phar.*

(5473) MUGILIDÆ, the Mullet Tribe, a family of Fishes of the order *Acanthopterygii.* This family may be distinguished by the following characters:—Body nearly cylindrical, covered with large scales: dorsal fins two in number separated, the first with only four spinous rays; the ventral fins have their origin a little behind the line of the pectorals; branchiostegous rays, six. The head is somewhat depressed, and, like the body, is covered with large scales or polygonal plates; the muzzle is very short; the mouth is transverse, and when closed forms an angle, the lower jaw having an eminence in the middle, which fits into a corresponding hollow in the upper; teeth very minute; pharyngeal bones much developed. There are three genera belonging to this family—*Atherina, Mugil,* and *Tetragonurus.*

Atherina has the body rather elongated; two dorsal fins widely separated; ventral fins placed far behind the pectorals; sides with a broad longitudinal silver band; teeth minute; branchiostegous rays 6.

Mugil has the body nearly cylindrical, covered with large scales; two dorsal fins widely separated, the rays of the first fin spinous, those of the second flexible; ventral fins behind the pectorals; middle of the under jaw with an elevated angular point, and a corresponding groove in the upper; teeth small; branchiostegous rays 6.

Tetragonurus, so named from the projecting keels or riges on each side, near the base of the caudal. There is only one species, an inhabitant of the Mediterranean, about a foot long, and black, and reputed to be poisonous.—*Eng. Cyc.*

(5474) MUGIL, Mullet Large. A species of mullet is very common in Tenasserim and is often seen on the tables of Europeans, by whom it is highly esteemed. Mr. Blyth, to whom I sent a specimen for the determination of the species, wrote that it was abundant in Calcutta, but "is of a species I could never determine from descriptions."—*Mason.*

(5475) MUKHUM SEEM. Dolichos Gladiatus. Sabre Bean. This is a large kind of bean, grown at the same time as others; it requires strong support to run over. The beans are dressed as French beans but are not so tender.—*Riddell.*

(5476) MULBERRY. Morus Indica.

(5477) MULLET FISH. Mugil cephalus.

Maddava meen, Tam. | Bonta, Tel.
Arabie mutchie, Duk. | Purhid, Hin

Ain's Mat. Med. p. 155.

(5478) MULLET, Mugil cepsalotus, *Vallenciennes,* large eyed. The Tenasserim seas have another mullet, equally valuable for the table with the last, and equally common in Calcutta, but distinguished among other things by its small head, smaller scales, and goggle eyes which appear to be starting out of its head.—*Mason.*

(5479) MULLET. Mugil subviridis, *Vallenciennes,* small. A small mullet is often found in great numbers in the river near Maulmain, which many of the Burmese regard as the young of the preceding, but it is a distinct species, of which Mr. Blyth wrote that he had never seen it before, but had "made it out to be as above."—*Mason.*

(5480) MULLET. [Mugilidæ; Multus.]

(5481) MULLUS, a genus of Fishes belonging to the group *Acanthopterygii* and the family *Percidæ.* The species have the body thick oblong; profile of the head approaching to a vertical line; scales large, deciduous; two dorsal fins widely separated, the rays of the first spinous, those of the second flexible; teeth on the lower jaw and palate only; two cirri at the symphysis of the lower jaw; branchiostegous rays 4. There are two species of this genus found in Europe, and both are inhabitants of the seas of Great Britain.

(5482) MULMURACA, the Tamil name of a tree which grows to about twenty-four inches in diameter, and twenty feet in height. It is used by the natives for canoes, catamarans, and many other purposes. It produces a fruit which, with the leaves of the tree, is used medicinally.—*Edye. Ceylon.*

(5483) MUM. A fermented liquor, brewed principally from the malt of wheat.—*Faulkner.*

(5484) MUNDAREKAI, Tam. This article Ainslie had never seen. It grows in the extreme Southern parts of the Peninsula, and is eaten by the common people.—*Ainslie, p.* 241.

(5485) MUNGEVENAH, the Tamil name of a Ceylon tree which grows to thirty inches in diameter, and eight feet long. It is close in its grain and light. It is used for gun-stocks, poles of palanquins, sandals, &c. It produces a fruit which is of little use. It is on the fruit of this tree that the monkeys, pea-fowl, &c. feed.—*Edye. Ceylon.*

(5486) MUNJEET, Indian Madder.

Munjeet, Guz. & Hind.

Rubia Munjistha, or Indian madder root,

growing in various parts of India, Persia, &c. It is used in dyeing, and is applied to the same purposes as Europe madder. The roots are long, about the thickness of a quill, with a smell somewhat resembling liquorice-root. Munjeet is largely imported into Bombay from the Persian Gulf and Kurrachee, and is chiefly re-exported to England.—*Faulkner.* See MADDER,

(5487) MUNJUN. A tooth powder, made of burnt almond shells; or common charcoal: or charcoal made from myrobalans or betel nuts.—*Herklots.*

(5488) MUNSOOR ALI KHAN. An almost direct road from Hoomayoon's tomb near Delhi, leads to a mausoleum of some celebrity, viz. that of (Nawab Munsoor Allee Khan,) Sufdur Jung, one of the Omrahs of Delhi. Before the accession of the British dominion, he and his ancestors, it is said, held the Soobahdaree of Oude. This native nobleman's remains were either interred here or the building answers the purpose of a cenotaph. It is a substantial work of red stone so common in many of the edifices of Delhi. It is in many parts relieved with marble, is surmounted by a large white marble dome, forms a structure of some magnitude and is said to be about 150 years old. The tomb stone on the upper floor and on a line with the sarcophagus is a chaste piece of sculpture of white marble, and the leaves which surround its base form an excellent and neat specimen of the power of the chisel in the hands of art. The mausoleum is situated in the centre of a large area of enclosed ground laid out into a fine garden and occupies an isolated position on the main road which connects Delhi with the Kootub.—*Tour in India by French, p.* 13.

(5489) MURÆNIDÆ, or ANGUILLIDÆ, a family of Fishes belonging to the Apodal section of the *Malacopterygii.* These fishes have an elongated and often cylindrical body, covered by a thick and soft skin in which the scales are deeply imbedded and scarcely apparent. They have no cæca, but nearly all are furnished with a natatory bladder. In the first group, which constitutes the great genus *Muræna* of Linnæus, the opercula are small, and enveloped in the skin; the gill-opening is small, and is situated far back, an arrangement which, by more completely protecting the branchiæ, permits these fishes to live a long time out of water. They have no ventral fins. The species of the genus *Anguilla* are distinguished by the possession of pectoral fins; the dorsal, anal, and caudal fins are united, the dorsal commences at a considerable distance behind the pectorals; the upper jaw is shorter than the lower; the gills opening by a small aperture on each side, situated beneath the pectoral fin. Three if not four species of *Anguilla,* or Eel, are found in Britain—the Sharp-Nosed Eel, the Broad-Nosed Eel, and the Snig.—*Eng. Cyc.*

(5490) MURIATIC ACID, MARINE ACID, SPIRIT OF SALT, HYDROCHLORIC ACID, CHLOROHYDRIC ACID.

Loona rasa, CYNG.	Nemuk ka Teezab, HIND.
Acide Hydrochlorique, FR.	Acidum Muriaticum, Spiritus Salis, LAT.
Salzsaure, Chlorwasserstoffsaure, GER.	Ooppoo travagum, TAM. Lawana travagum, TEL.

This acid is a solution of the gas in water. Geber and the Arabs were probably acquainted with it, and the Hindoos knew it by a name equivalent to *Spirit* or *sharp water of Salt.* This is the Commercial acid, and is always of a yellow colour. It commonly contains as impurities a little Sulphuric Acid, Nitrous Acid, Perchloride of Iron, Chlorine, and Bromine. It is prepared by pouring the Oil of Vitriol of commerce on Common Salt in earthen or iron vessels, especially since the extensive manufacture of Carbonate of Soda from Sulphate of Soda. Its Density,= 1180.—*Royle, p.* 46.

(5491) MURICIA COCHINCHINENSIS. A native of China, Cochin China, a large shrub, berry large, reddish purple, scentless, insipid; seeds and leaves aperient, and used by the Chinese in obstructions of the liver, "tumors, malignant ulcerations, &c." externally employed in fractures, and in dislocations. (Lindley).—*OSh. p.* 351.

(5492) MURIDÆ, the name of an extensive family of Rodents, comprising, when taken in its largest sense, a great number of genera and species, which, though none of them attain to any considerable size, become worthy of serious notice from their prodigious multiplication and the destructive influence which they exert over vegetation and the fruits of the labour of the agriculturist. The type of this family is found in the genus *Mus,* to which our Common Rats and Mice belong. The Linnean genus *Mus* is thus characterised in the last edition of the 'Systema Naturæ:'—'Dentes primores inferiores subulati;' and, as might be expected from such a definition, it is made the receptacle not only for such Rodents as are vernacularly known as Rats and Mice, but for the Guinea Pig, the Agoutis, the Paca; in short, for all the *Glires* then known, not arranged under the genera *Hystrix, Lipus, Castor* and *Sciurus.* The remaining genus (*Noctilio*), placed by Linnæus among his *Glires,* belongs to the Bats. [CHEIROPTERA.] Pallas concurred with Linnæus in uniting under one great genus (*Mus*) all the Rodents provided with clavicles which had no striking external distinction, such as the tail of the Squirrel or the Beaver. Mr. Swainson in his 'Classification of Quadrupeds' (1835) also separates the *Glires* into two divisions: the first, or *Glires* proper, with clavicles; and the second with rudimentary clavicles, or none. In the first division, after the genera *Castor, Fiber* and *Mybpotomus,* and an observation in a note

to the first section, that these divisions are purely artificial, and nearly formed to facilitate the search among so many unarranged groups, we find the following sections :—

1. Rats and Mice, under which are arranged the following :—*Arvicola*, Lacép. (*Hypudæus*, Ill.) Example, *Mus amphibius*, Linn., Water-Rat, Penn. ; *Georychus*, Ill. (Lemmings). Example, *Mus Norvegicus*, Linn., the Lemming. *Echimys*, Geoff. (Spined Rats). Ex. *Echimys cristatus*, Desm., Gilt-Tailed Dormouse, Penn. *Myoxes*, Gm. (Dormouse). Ex. *Mus avellanarius*, Linn, the Common Dormouse. *Hydromys* Geoff. (Water-Rat). Ex. *H. leucogastor*, Australia. *Mus*, Auct. Ex. *M. Rattus*, Linn., Common Rat. *Capromys*, Desm. Ex. *C. prehensilis* South America. *Cricetus*, (Hamster). Ex. *C. vulgaris*, the Hamster.

2. Fore legs very short, hind legs long. Jumping Mice, under which come the following genera and subgenera :—*Dipus* (Jerboa). Ex. *Mus Jaculus*, Linn. (*D. Sagitta*, Dum.) Sub-genus *Gerbillus*, Desm. Ex. *M. Tamariscinus*, Tamarisk Jerboa, Sh. *Meriones*, L. Cuv. Ex. *Meriones Labradorius*, Sub-genus *Pedetes*, Ill. Ex. *M. Caffer*, Pall., Cape Jerboa, Penn. Then follows *Lagostomus*, *Brookes*, with its sub-genera *Chinchilla* and *Logotis*. [CHINCHILLIDÆ.]

3. Tail very short. Mole and Sand-Rats, including *Geomys*, Schmaltz (Saud-Rat). Ex. *Geomys Douglasii*, America. *Diplostoma*, Schmaltz, America ; *Aplodontia*, Richardson. Ex. *A. leporina*, America. *Aspalax*, Guld. Ex. *Mus Typhlus*, Pall., Asia ; *Bathyergus*, Ill. Ex. *M. maritimus*. Gm., Africa.

4. Tail long, bushy. Squirrels, under which are arranged *Arctomys*, Gm. Ex. *Mus Marmotta*, Linn., the Marmot. *Spermophilus*, F. Cuv. Ex. *M. citellus*, Pall., chiefly America. *Sciurus* Auct. Ex. *S. vulgaris*, Linn., the Common Squirrel ; together with the sub-genus *Pteromys*, Geoff. and the genus *Cheriomys*. The numerous forms which press upon the attention in considering this large section of *Mammala* are enough to convince any one who has bestowed any thought on the subject that authors have not spoken of the difficulties surrounding it without reason. General Hardwicke gives the following interesting account of his *Dipus Indicus* :—"These animals are very numerous about cultivated lands and particularly destructive to wheat and barley crops, of which they lay up considerable hoards in spacious burrows near the scenes of their plunder. They cut the culms of the ripening corn just beneath the ears, and convey them thus entire to one common subterraneous repository, which when filled they carefully close, and do not open for use till supplies abroad become distant and scarce. Grain of all kinds is their favourite food ; but in default of this they have recourse to the roots of grass and other vegetables. About the close of day they issue from their burrows, and traverse the plains in all directions to a considerable distance ; they run fast, but oftener leap, making bounds of four or five yards at a time, carrying the tail extended in a horizontal direction. When eating they sit on their hind legs like a squirrel, holding the food between their fore feet. They never appear by day, neither do they commit depredations within doors. I have observed their manners by night, in moonlight nights, taking my station on a plain, and remaining for some time with as little motion as possible. I was soon surrounded by hundreds at the distance of a few yards ; but on rising from my seat the whole disappeared in an instant, nor did they venture forth again for ten minutes after, and then with much caution and circumspection. "A tribe of low Hindus, called Kunjers, whose occupation is hunting, go in quest of these animals at proper seasons, to plunder their hoards of grains ; and often, within the space of twenty yards square, find as much corn in the ear as could be crammed into a common bushel. They inhabit dry situations, and are often found at the distance of some miles out of the reach of water to drink. In confinement this animal soon becomes reconciled to its situation, and docile ; sleeps much in the day, but when awake feeds as freely as by night. The Hindus above mentioned esteem them good and nutritious food." ('Linn. Trans.,' vol. viii.). In the collection of the British Museum the student will find specimens of nearly all the Asiatic *Murida* at present known. The following is a list of the species found in that collection, with the Asiatic countries in which the specimens were found :—

Family *Muridæ*.

a. Murina.

Acanthomys Cahirinus, the Cairo Rat. Egypt.

A. affinis, the Allied Acanthomys.

Mus Bandicota (Bechstein), the Bandicoot, or Pig-Rat. Nepaul.

M. nitidus (Hodgson), the Shining Rat. Nepaul.

M. gigas, the Egyptian Bandicoot. Egypt.

M. decumanus (Pallas), the Norway Rat. Great Britain and India.

M. Decumanoides (Hodgson), the Indian Rat. Nepaul.

M. Asiaticus (Gray), the Asiatic Rat. Mexico and India.

M. niviventer (Hodgson), the White-Bellied Rat. Nepaul.

M. Kok (Gray), the Kok. India.

M. Abyssinicus (Ruppell), the Abyssinian Rat. Abyssinia.

M. Ellioti, Elliot's Rat. Madras.

M. rufescens (Gray), the Red House-Rat. India.

M. albipes (Ruppell), the White-Footed Rat. Abyssinia.

M. leucosterum (Ruppell), the White-Crested Rat. Abyssinia.

M. variegatus (Brants), the Variegated Rat. Egypt.

M. Mauci, the Mauci. Madras.

Vandeleuria oleracia (Gray), the Meinalka. Madras.

V. dumeticola, Hodgson's Free Mouse. Nepaul.

Nesokia Hardwickii (Gray), the Nesoki. India.

Golunda Ellioti (Gray), the Galandi. Madras.

G. Meltada (Gray), the Meltada. Madras.

Leggada Booduga (Gray), the Buduga. Madras.

L. platythrix (Gray), the Leggade. Madras.

Phlæomys Cumingii (Waterhouse), the Phlæomys. Manilla.

b. Arvicolina.

Arvicola Roylei (Gray), the Indian Vole. India.

A. (?) *hydrophilus* (Hodgson), the Nepaul. Vole. India.—*Eng. Cyc.*

(5493) MURRAYA. BURMAN BOX-WOOD. The Karens sometimes furnished specimens of a wood that can scarcely be distinguished from the box-wood of Europe, but he had never seen the tree though Mr. Mason has named it a Murraya. Wallich found *Nauclea cordifolia* on the banks of the Irrawaddy, which has "wood coloured like that of the box tree, but much lighter, and at the same time very close grained." It may possibly be the same tree, although the Tenasserim wood is not light; or it may be a Tavoy tree, which he says has "a strong tough wood, in grain like box."—*Mason.*

(5494) MURRAYA EXOTICA. Lin. *Aurantiaceæ.* NAT. BIBZAR OR KOONTIE. This most beautiful shrub is not a native of India so has no Tamool or Teloogoo name. The fragrance of its delicate white flowers is delightful and has procured for it the name of the Honey bush.—*Ainslie's Mat. Med. p.* 162. Dr. Riddell describes it as an ornamental shrub, with beautiful dark green leaves; flowers white, and fragrant in the evening, and commonly known by the name of China-box; it is to be found in most gardens, and is easily grown by layers or cuttings. —*Riddell.* MURRAYA EXOTICA, and PANICULATA and the Aglaia odorata, are cultivated in China as very fragrant shrubs.—*Williams.* Dr. Hooker says that he found the woods of the Rajabat in the Soane valley full of monkeys, and amongst other plants, observed *Murraya exotica*, but it was scarce.—*Hooker Him. Jour. Vol.* I. *p.* 44.

(5495) MURRAYA PANICULATA. COSMETIC BARK. A small tree, with pinnate leaves; flowers white and fragrant, appear in Dec. and Jan.; fruit reddish.—*Riddell.* The fragrant bark of this tree which is indigenous in Burmah above Rangoon, is more universally used for a cosmetic than sandal wood. A single specimen has been shown Mr. Mason in Maulmain, which is this very ornamental fragrant flowering shrub of the citron tribe.—*Mason.*

(5496) MURTHY WOOD.

(5497) MURVILINGA, or Marvilingum Maram, the Tamil name of a Ceylon tree which grows to about sixteen inches in diameter, and eight feet high. It is prized by the natives for sandals and toys, &c. It produces a kind of pod, which, with the bark and leaves, is used with much success in cases of intermittent fevers.—*Edye. Ceylon.*

(5498) MUSA, a genus of Endogenous Plants the type of the natural order *Musaceæ.* The species consist of herbaceous plants, having a gigantic simple stem, thickly clothed with the sheathing petioles of long, broad, horizontal leaves, which form a tuft, like that of some palm on the apex of the stem. These leaves are of a firm but thin texture, and are undivided; but having simple veins running directly from the margin towards the midrib, and presenting a broad surface to the wind, they are always torn into broad strap-like divisions, which give them a compound appearance. From the midst of these leaves proceeds the inflorescence, consisting of a compound spike of great size, each of whose divisions is inclosed in a large bract or spathe loaded with male flowers at its base, but bearing females or hermaphrodites at the upper end. The perianth consists of 6 superior divisions, five of which are grown together into a tube, slit at the back, while the sixth is small and concave. There are 6 stamens, one or more of which are imperfect. The ovary is inferior, 3-celled, with the double row of numerous ovules in each cell; the style is short; the stigma is funnel-shaped, and obscurely 6-lobed. The fruit is an oblong fleshy body, obscurely 3-5-cornered, containing numerous seeds buried in pulp. The latter are roundish, the size of a pea, flattened, with a hard brittle shell, which is indented at the hilum. This genus is one of the most important of those found in tropical countries, to which the species are confined in a wild state. The *M. Sapientum*, or Plaintain, of which the Banana, or *M. paradisiaca*, is a slight variety, has fruit used to a prodigious extent by the inhabitants of the torrid zone; and, from its nutritious qualities and general use, it may, whether used in a raw or dressed form, be regarded rather as a necessary article of food than as an occasional luxury. In equinoctial Asia and America, in tropical Africa, in the islands of the Atlantic and Pacific ocean, wherever the mean heat of

the year exceeds 24 centigrade degree (75° Fahrenheit), the plantain is one of the most interesting objects of cultivation for the subsistance of man. Three dozen fruits will maintain a person, instead of bread, for a week, and even appears a better diet in warm countries. Indeed the plantain is often the whole support of an Indian family. The fruit is produced from among the immense leaves, in bunches weighing from 30 to 80 lbs., of various colours, and of great diversity of form. It usually is long and narrow, of a pale-yellow or dark-red colour, with a yellow farinaceous flesh. But in form it varies to oblong and nearly spherical; and in colour it offers all the shades and variations of tints that the combination of yellow and red, in different proportions, can produce. Some sorts are said always to be of a bright-green colour. In general, the character of the fruit to an European palate is that of mild inspidity; some sorts are even so coarse as not to be edible without preparation. The greater number however are eaten in their raw state, and some varieties acquire by cultivation a very exquisite flavour, even surpassing the finest pear. In the better sorts the flesh has a fine butter-yellow colour, is of a delicate taste, and melts in the mouth like marmalade. To point out all the kinds that are cultivated in the East Indies alone would be as difficult as to describe the varieties of apples and pears in Europe, for the names vary according to the form, size, taste, and colour of the fruits. Sixteen principal kinds are described at length by Rumphius, from which all the others seem to have diverged. Of these the worst are, Pisang Swangi, Pisang Tando, and Pisang Gabba-Gabb; and the best are the round soft, yellowish sorts, called Pisang Medji and Pisang Radja. Some cultivators at Batavia boast of having 80 sorts. Rheede distinguishes 14 varieties by name, as natives of Malabar. In Sumatra alone 20 varieties are cultivated, among which the Pisang Amas, or Small Yellow Plantain, is esteemed the most delicate, and next to that the Pisang Raja, Pisang Dingen, and Pisang Kalleé. In the West Indies, plantains appear to be even more extensively employed than in the eastern world. The modes of eating them are various. The best sorts are served up raw at table, as in the East Indies, and have been compared for flavour to an excellent reinette apple after its sweetness has been condensed by keeping through the winter. Sometimes they are baked in their skins, and then they taste like the best stewed pears of Europe. They are also the principal ingredient in a variety of dishes, particularly in one called mantague, which is made of slices of them fried in butter and powdered over with fine sugar. Of the many cultivated sorts, that called by the French La Banane Musquee is considered the best; it is less than the others, but has a more delicate flavour. There are uncoloured figures of the plantain fruit in Rheede's 'Hortus Malabaricus,' vol. i., plates 12,-13, and 14; and coloured ones in Tussac's 'Flore des Antilles,' plates 1, 2. All hot climates seem equally congenial to the growth of this plant; in Cuba it is even cultivated in situations where the thermometer descends to 7 centesimal degrees (45° Fahrenheit), and sometimes nearly to freezing point. There is a hardy variety called Camburi, which is grown with success at Malaga. The Plantain prefers a rich fat soil; for in sandy places, where it flowers abundantly, it produces no fruit. In the climates that suit it, there is no plant more extensively useful, independently of its being an indispensable article of food. A tough fibre, capable of being made into thread of great fineness, is obtained from its stem; and the leaves, from their breadth and hardness, form an excellent material for the thatch of cottages. An intoxicating liquor is also made from the fruits when fermented, and the young shoots are eaten as a delicate vegetable. The Banana of hot countries is a mere variety of the Plantain, distinguished by being dwarf, with a spotted stem and a more delicate fruit. Botanists call it *Musa paradisiaca*, in allusion to an old notion that it was the Forbidden Fruit of Scripture; it has also been supposed to be what was intended by the grapes, one bunch of which was borne upon a pole between two men, that the spies of Moses brought out of the Promised Land. The only argument of any importance in support of the latter opinion is, there is no other fruit to which the weight of the fruit of Scripture will apply. All the genus is Asiatic; the wild plantain is found in the forests of Chittagong. where it blossoms during the rains; *M. coccinea*, a dwarf sort, with a stem not more than 3 or 4 feet high, is found in China; *M. ornata* and *M. superba* inhabit the forests of Bengal: *M. glauca* is from Pegu; *M. textilis* is from the Philippines, where it furnishes the valuable thread called Manilla Hemp. There is also in the gardens of England a plant called *M. Cavendishii*, not above 3 feet high, and fruiting abundantly at that size, the origin of which is said to be Mauritius.—*Eng. Cyc.* The name of this family of plants, derived from *Musa*, is, so classically sounding, that we are apt to forget its probably oriental origin. For being natives of tropical countries, though often extending beyond such limits, and having the name of *mauz* or *moz* applied to one of the species by old Arabic writers, there is very little doubt of this being the source of the name *Musa*. This is now applied to the genus which produces the fruits commonly known as Plantains and Bananas; as also the fibre so well known under the name of Manilla Hemp. The Plantain was undoubtedly known by description both to the Greeks and Romans, for Theophrastus, among the plants of India, describes one as having fruit which serves

as food for the wise men of India: and which was remarkable both for its sweetness and for its size, as one would suffice for four men—referring most propably to a bunch of plantains. Pliny, evidently describing the same plant, informs us that its name was *Pala*. Garcias, in comparatively modern times, describing the plantain, states that its name on the Malabar coast was *Palan*. The plants of Musa are conspicuous for their size among herbaceous plants. They are devoid of true stems, but form a spurious stem, often of considerable thickness, from the leaves, as they rise from the root-stock, being sheathing at their base, encircling each other, and enveloping, layer within layer, the slender flower and fruit-stalk. This, rising through the centre, projects and hangs down from the top of the sheathing part of the leaves. These, at this point, expand into broad, and at the same time long laminæ or blades, in which numerous parallel veins proceed at right angles from the thick midrib to the margin of each leaf. As these veins do not anastomose and form a network as in ordinary leaves, the leaves are apt, when blown about by the wind, to be divided into innumerable narrow shreds, which are still attached to the midrib. This appearance, no doubt, suggested and justifies the leaves being said to be like ostrich feathers. Every part, both of the sheathing and the exposed parts of these leaves, abounds in fibre. The species of Musa are found in hot and tropical parts of the world, as in the Philippine Isles, where *Musa textilis* is indigenous, as well as in those of the Indian Archipelago, where the edible species are common. From thence they extend northwards as far as Japan; while in China are found *Musa coccinea* and *Cavendishii*; also along the Malayan Peninsula to Chittagong—*M. glauca* being indigenous in the former, and *M. ornata* in the latter locality. In the valleys of the south of the Peninsula of India and of the Dindygul Mountains, *M. superba* is found. The common edible varieties of *M. paradisica* flourish even in the poorest soils, and also near brackish water. They are extensively cultivated at stations in the interior. On the Malabar coast, the Plantain is everywhere at home. The fruit of those at Bassein is especially well-flavoured, and the plant is particularly abundant in the district of Broach. If from the west we return to the east of India, we find the Plantain and Banana most extensively cultivated. The Plantain, according to Dr. Helfer, is to be found in the highest perfection in Tenasserim, especially in province Amherst. More than twenty varieties are known, of which several are peculiar to the country, and the greatest part of them are superior to any to be got in Bengal. They thrive well everywhere without the slightest care. No Burmah or Karen house is to be found without a plantation of Plantains. As the latter leave their abodes, at least every three years, in order to migrate to fresh localities, they are, of course, obliged to leave their Plantain gardens behind them, and therefore these may be found growing luxuriantly in many uninhabited places, until they become choked up by the growth of the more vigorous jungle trees. With the Plantain, as with other long cultivated plants, many distinct varieties are recognised and named, but which it is extremely difficult to arrange in suitable order. But the natives of Bengal generally prefer the large and coarse-fruited kinds, called Plantain; while the smaller and more delicately tasted fruit, known as the Banana is alone esteemed by Europeans. These are cultivated in the most northern, as well as in the southern parts of India; while along the jungly base of the Himalayas there is a suitable climate as far as 30° of north latitude, for plants of this genus growing in a wild state. That growing in Nepal has been called *M. nepalensis*. A similar species may be seen growing below the Mussoore range, as well as near Nahn. The fruit, however, in all these situations, consists of litttle else than the hard dry seeds. [A similar variety of *Musa sapientum*, having seeds surrounded with a gummy substance, instead of fruit-like pulp, was found by Dr. Finlayson, on Pulo Ubi, near the southern extremity of Cambodia. In Batavia also, there is stated to be a variety full of seeds, which is called *Pisang batu*, or *Pisang bidju*—that is, Seed Plantain. In Kemaon and Gurhwal it is cultivated at as great an elevation as 4000 and 5000 feet above the sea, and has been seen as far north as the Chumba range at an equal elevation. Major Munro has seen the wild Plantain at 7000 feet above the sea, in the Khondah slopes of the Neilgherries. Though many of the above have been mentioned as distinct species, it is probable that some, at least, are only varieties. "Baron Humboldt has suggested, that several species of Musa may possibly be confounded under the names of Plantain and Banana, and that some of these may be indigenous to America; but as stated by Mr. Brown, nothing has been advanced to prevent all the cultivated varieties being derived from one species, *Musa Sapientum* (also called *M. paradisiaca*), of which the original is the wild Musa, described by Dr. Roxburgh as grown from seed received from Chittagong. Mr. Brown further adds, that it is not even asserted that the type of any of those supposed species of American Banana, growing without cultivation and producing perfect seed, have anywhere been found." ('Illust. of Himal. Bot.,' p. 355.) If the Plantain and Banana are therefore natives of Asia, which have been introduced, probably, by the Spaniards into America, no plants can more strikingly display the benefits derivable to one country from introducing the useful plants of another which is similar in climate. For Plan-

tains and Bananas are now extensively cultivated in various parts of South America, and at an elevation of 3000 feet in the Caraccas. They are abundant in the West India Islands, as well as at considerable elevations in Mexico. To the negroes in the West Indies, the plantain is invaluable, and like bread to the European, is with them denominated the staff of life. In Guiana, Demerara, Jamaica, Trinidad, and other principal colonies, many thousand acres are planted with the Plaintain. But, before proceeding to treat of the Plaintain and Banana, it is desirable to notice the species which yields Manilla Hemp, showing how valuable some of these plants are, on account of their fibres — *Royle Fib. Plants.*

(5499) MUSACEÆ, *Musads*, a natural order of Endogens, of which the genus *Musa* is the representative. They are stemless or nearly stemless plants, with leaves sheathing at the base and forming a kind of spurious stem, often very large; their limb separated from the taper petiole by a round tumour, and having five parallel veins diverging regularly from the midrib towards the margin. Flowers spathaceous: perianth 6-parted, adherent, petaloid, in two distinct rows, more or less irregular; stamens 6, inserted upon the middle of the divisions, some always becoming abortive; anthers linear, turned inwards, 2-celled, often having a membranous petaloid crest; ovary inferior, 3-celled, many-seeded, rarely 3-seeded; ovulus anatropal; style simple; stigma usually 3-lobed. Fruit either a 3-celled capsule, with a coculicidal dehiscence or succulent and indehiscent. Seeds continuous, surrounded by hairs, with an integument which is usually crustaceous; embryo orthotropal, oblong-linear, or mushroom-shaped, with the radicular end touching the hilum, having pierced through the mealy albumen. The species are stately and always beautiful herbaceous plants with the aspect of a plantain, and with large bracts and spathes, which are usually coloured of some gay tint. The characteristic marks of the order are to have an inferior ovary, with very irregular and unsymmetrical flowers, whose sexual apparatus is not consolidated. It is chiefly by these distinctions that it is known from *Amaryllidaceæ*. In some the fruit is fleshy, as in the Plantain; in others it is dry and capsular. Only 4 genera are known of this order, consisting of about 20 species, all of striking beauty. *Heliconia* is the principal American form nearly all the others being found in the Old World; of these the species are conspicuous for their brilliantly-coloured rigid boat-shaped bracts, sometimes yellow, sometimes scarlet and even a mixture of both. The species of *Strelitzia* are Cape plants with rigid glaucous leaves, and singularly irregular flowers of considerable size, coloured yellow and blue or pure white. Finally, the Ravenula of Madagascar (*Urania speciosa*), a noble palm-like plant, is remarkable for the brilliant blue colour of the lacerated pulpy aril which envelopes the seeds; the latter are used for dyeing in Madagascar, but none of the order are of any important use to man, with the exception of the Musas themselves. [MUSA.]

Ainslie's Mat. Med. p. 261.

Of this delicious fruit there is a great variety in lower India, three of the most esteemed sorts are the Rajah plantain, the red and the yellow. Plantains in their green state are sliced and made into curry, when they eat not unlike potatoes. The natives particularly the Mahometans consider plantains as highly nutritious and eat them with cows milk and sugar as we do strawberries. — *Ainslie, p.* 234. The plantain and Banana, though probably only varieties of one species, are yet sufficiently distinguished by the size and flavour of their fruit, to be considered familiarly as distinct. They are, from their luxuriant-growing and large overhanging leaves, considered among the most characteristic forms of tropical vegetation. They are also among the most valuable of plants, inasmuch as in some countries they supply the place of bread, and form the chief nutriment of the people. But not only does the Plantain supply the place of bread and serve as fruit, but also in a preserved state as desert. The farinaceous parts may, moreover, be separated in the form of flour, and are probably as nutritious as rice. The shoots or tops of the young plants, both in the East and the West, are occasionally given as fodder to sheep and cattle, and are described by some as a delicate edible. The leaves, in a dried state, are used for thatching and bedding. Both the stem and leaves abound in fibre, useful for textile or cordage purposes, while the tow which is separated in preparing the fibres, forms an excellent material for the finest or the toughest kinds of paper. The illustrious Humboldt has long since remarked, that the Banana is for the torrid zone what the Cerealia are for Europe and Western Asia, or rice for Bengal and China, forming a valuable cultivation wherever the mean temperature of the year is about 75°. He has also calculated that the same extent of ground, when planted with the Banana, will support a far greater number of people than when planted with wheat. As this is a point of great economical interest, it has been a subject of subsequent investigation. The productiveness has been found to differ with the mean temperature of the place. Boussingault has

given the following as the produce, per imperial acre, of the raw fruit in three places, according to Humboldt's (1), Gondot's (2), and his own observations (3):

	Temperature.	Produce, per imperial acre.	Or of dry food, per acre.
(1) In warm regions	81½ Fah.	72 tons.	19½ tons.
(2) At Cauca	78⅘ ,,	59 ,,	16 ,,
(3) At Hague	71⅚ ,,	25 ,,	6¾ ,,

Professor Johnston is the authority for the last column, or that of dry food per acre, as he had, from his analysis, obtained 27 per cent. of nutritive matter from the Banana. He justly observes, that all these quantities are very large, and show how easily life may be supported in tropical countries. And further, that as potatoes contain about one fourth their weight of dry nutritive matter, it would require a crop of twenty-seven tons of potatoes per imperial acre, to yield the smallest of the quantities above mentioned as the yield of an acre of Plantains; while only twenty to twenty-four tons of potatoes are obtained in favourable seasons and localities. Though it is not probable that the Plantain is cultivated in India, with the care to enable the largest possible quantity of produce to be obtained, yet there is no doubt that the produce is large and the culture most simple. It would be an interesting subject of experiment for the Agricultural Societies of India, to ascertain which are the most productive varieties; whether the modes of cultivation adopted in that country have attained the highest limits of productiveness; and also to determine the best methods for preserving the fruit in different places; and also, when superabundant, whether its meal might not be preserved for periods of scarcity, or for the season of pthe year when the fresh fruit is not rocurable. In South America the fruit is not only used as an article of diet in its fresh state, but, when dried, forms an article of internal trade, besides having its flour separated, and cooked or made into biscuits. It is also preserved in the Society Islands. The preservation of the fruit and the preparation of the meal has already been introduced into India. Some Plantain meal was sent to the Exhibition of 1851, from Madras, as well as baked Plantains from Jessore, by the Rev. J. Parry. These, after some years, are still in good preservation and well tasted. The late Dr. Stocks, and the loss is great which Science and the East India Service have sustained, in the death of this accomplished naturalist, who was as remarkable for the variety of his attainments, as for his zeal for botanical science and its application to practical purposes, informed Dr. Royle that the Plantains at Bassein, where the cultivation is most extensive, are delicious in flavour, and that there the people had acquired the art of preserving them. But this was practised many years ago in Central India, and in Ceylon in 1840, the late Sir John Robison, Secretary of the Royal

Society of Edinburgh, wrote to Dr. Royle some years since: "Among the products of India, which, I think, might be easily brought into general sale in England, are some of the fruits which, if cut in slices and dried in the sun, would become as susceptible of transport, as those of the Levant and the South of France. Above all, the Banana, of which the varieties, which are rich in saccharine matter, make an admirable preserve, on being skinned and split longitudinally and dried in the sun, by which process they immediately acquire a consistence like Turkey figs, and become capable of being packed and preserved in the same way." He concludes by stating: "I was in the habit of having large quantities preserved every year in this way at Hyderabad, and of using them as an article of dessert at table." In treating of the culivation of species of Musa or Plantain in India for fibre, it is desirable to advert to the cultivation of the edible species, or the numerous varieties included under the names of Banana and of Plantain, and suggesting them as above as subjects of experiment to members of the Agricultural Societies in India, to ascertain whether the modes of cultivation adopted in India have attained the highest limits of productiveness; and also whether the fruit might not be preserved in different forms. Dr. Royle has already observed that a remarkable instance of the great length of time for which these Plantains may be preserved in an eatable state, occurred at the Exhibition of 1851. There were some preserved Plantains, "Plantano pasado," which had been brought home by Lieut.-Col. Colquhoun, R.A., from the province of Jatisco (Guadalaxara), Mexico, in the year 1835, and which since then had remained neglected in a baggage warehouse. The specimen exhibited was the remainder of a package of 75 lb weight, made up, as customary, in the leaves and fibre of the plant, after having been subjected to considerable pressure. The state of preservation, after sixteen years, was favorably reported on by Dr. Lindley, and no signs of decomposition were then perceptible in the specimens given to Dr. Royle by Colonel, now Sir W. Reid; the sugar of the fruit having been sufficient to preserve them. They are prepared in considerable quantities in the hot region (tierra caliente) of the western coast of Mexico, for consumption in the elevated districts of the interior. The Silver Medal of the Society of Arts was awarded for the first samples brought to England. *See* the 'Transactions,' vol. I, p. 43, for the method of preparation, reprinted in 'Trans. Agric. Soc. of India,' viii, p. 60. Before, however, proceeding to detail the methods of preservation of the fruit, or the preparation of the meal, it is desirable to notice the relative values of these as compared with other kinds of fruit. This we are enabled to do from an excellent

Report 'On the composition and nutritive value of Plantain Meal,' by Professor Johnston, published in the 'Journal of the Highland and Agricultural Society of Scotland,' in 1848, and to which attention called by Professor Key, of Madras. By this we shall see that, in extending the culture of the Plantain, there is no probability of this ever becoming so extensive as for its fruit to become valueless.

Chemical Analysis of Plantain Fruit and Meal.

Extracts from a Report upon the 'Properties of the Plantain Meal.'—This meal is of a slightly brownish colour, and has an agreeable odour, which becomes more perceptible when warm water is poured upon it, and it has a considerable resemblance to that of Orris root. When mixed with cold water, it forms a feebly tenacious dough, more adhesive than that of oatmeal, but much less so than that of wheaten flour. When baked on a plate, this dough forms a cake which is agreeable to the sense of smell, and is by no means unpleasant to the taste. By washing with water this dough leaves a residue of insoluble tenacious gluten, as that of wheaten flour does. When filtered from the starch, the wash water gives no cloudiness when rendered slightly sour by Acetic Acid, when boiled yields a little coagulated albumen. Whether this is the case in the fresh fruit, or only in the dried meal prepared from it, I have had no opportunity of determining. The addition of Alcohol to the same watery solution renders it more or less distinctly gelatinous, as it does similar solutions obtained from other fruits, and form the turnip, parsnip, &c. This shows the presence of pectin, or pectic acid, the substance which in fruits, in the turnip, and in many other bulbous roots, takes the place of the starch found in grain, and in the tubers of the potato. When boiling water is poured over the meal, it is changed into a transparent jelly having an agreeable taste and smell. If it be boiled with water, it forms a thick gelatinous mass, very much like boiled sago in colour, but possessing a peculiar, pleasant odour.

Composition of the Plantain Meal.—By a careful analysis, the composition of the plantain meal was found to be nearly as follows:

a. The water.—Mr. Law states that 59 parts of the fruit yielded only 30·85 of eatable parts, which, on drying in the air, were reduced to 12·32 parts. The fruit, therefore, consisted in 100 parts of—

	Per cent.
Husks, &c.	47.71
Water evaporated by the sun	20·88
Meal dried in the sun	31.41
	100.00

MUSA PARADISIACA.

The meal thus dried in the open air, when dried again in the laboratory at 212° Fahr., lost 4·07 per cent. of water in addition; or one hundred parts of the recent fruit contain 27 of dry nutritive matter.

b. The albumen, &c.—By combustion the proportion of nitrogen in this meal, in its ordinary state, was found by Dr. Fromberg, in two experiments, to be 0·88 and 0·97 respectively, equal as a mean to 5·82 per cent. of protein compounds. These, as we have already seen, are most probably in the state of soluble albumen taken up by cold water, and of coagulated albumen attached to, or mixed with, the starch, cellular fibre, &c. In the perfectly dry meal the proportion is 6·75 per cent.

c. The ash.—When burned in the air, the proportion of ash left behind amounts to 2·32 per cent., or in the dried meal to 2·71 per cent. The entire composition of the plantain meal is represented in the following table:

	Dried in the air.	Dried at 212. Fah.
Water, ...	14·07	
Starch, ...	67·42	78·43

On comparing the above composition with that of other kinds of food commonly eaten by man, we find the plaintain *fruit* to approach most nearly in composition and nutritive value to the potato, and the plantain *meal* to those of rice. Thus the fruit of the plantain gives 27 per cent., and the raw potato 25 per cent. of dry matter. Again, the dry mealy matter of the plantain, of the potato, and of rice consists respectively of—

	Rice.	Potato.	Plantain.
Starch, ...	86·9	65·0	78·4
Sugar, Gum, &c.	0·5	15·0	7·6
Fat, ...	0·8	1·0	0·5
Cellular, ...	3·4	8·0	5 6
Protein compounds ...	7·5	8·0	5·2
Ash, ...	0·9	3·0	2·7
	100·0	100·0	100·0

or, comparing only the Starch, Sugar, &c., and the protein compounds, on which the nutritive

quality of these different vegetable productions principally depends, we have the following numbers :

	Rice.	Potato.	Plantain.
Starch, Sugar, &c. ...	67·4	79 0	86 0
Protein compounds, ...	7 5	8·0	5·2

These numbers show that it approaches, as I have said, nearest in its composition to rice, containing nearly as much starch, but a sensibly smaller proportion of the protein compounds, on which the sustenance of the muscles is supposed chiefly to depend. In regard to its value as a food for man in northern climates, there is no reason to believe that it is unfit to sustain life and health ; and as to warmer or tropical climates, this conclusion is of more weight. The only chemical writer who has previously made personal observations upon this point (M. Boussingault) says : " I have not sufficient data to determine the nutritive value of the banana, but I have reason to believe that it is superior to that of potato. I have given as rations to men employed at hard labour about 3 kilogrammes (6½ lb.) of half-ripe bananas, and 60 grammes (2 ounces) of salt meat." Of these green bananas he elsewhere states that 38 per cent. consisted of husk, and the internal eatable part lost 56 per cent. of water by drying in the sun. The 6·6 pounds, therefore, were composed of—

Husk, ...	2·5 lb.
Water, ...	2·3 ,,
Heart dried in the sun, ...	1·8 ,,
	6·6 lb.

so that less than two pounds a day of this dried banana fruit, which we may suppose to be equal in quality and composition to the sun-dried plantain meal, above described, with two ounces of salt meat per day, were found sufficient to maintain men, *not slaves*, at moderately hard labour. This was equal to 12½ lb. dried eatable banana, and 1 pound of salt meat (query fish) per week. * * * The composition of the ash of the Plantain also bears a close resemblance to that of the potato. Both contain much alkaline matter, potash and soda salts, and in both there is nearly the same per centage of phosphoric acid and magnesia. In so far, therefore, as the supply of those mineral ingredients is concerned, by which the body is supported as necessarily as by the organic food, there is no reason to doubt that the banana, equally with the potato, is fitted to sustain the strength of the animal body. It must not be denied that our present knowledge indicates the advantage of a mixture of food, as the most conducive to health and strength, but experience shows that however desirable, this is not absolutely necessary. The oat alone in Scotland raises and supports strong men ; rye alone does so in the north of Europe ; and the potato alone does so in Ireland. This result of experience in the case of the potato justifies us, were there no experience on the subject in tropical countries, in believing that the banana, which resembles it, will do the same. Whatever other reasons may lead us to recommend a mixture of other food with it, especially where *hard* labour, perhaps not a natural condition of things, is required of him, we ought not to base this recommendation upon any belief that the banana, when eaten alone, will not fully supply all the ordinary wants of the living animal.

Cultivation.—The plantain has thus been proved to be valuable on account of its fruit, both in its unripe and ripe state, the latter both when fresh and when preserved, and for yielding nutritious meal. The plant is also to be esteemed on account of the fibre with which every part of it abounds. Though both the Plantain and the Banana are to be found near the huts of the poor and in the gardens of the rich, the most profitable mode of culture has, probably, in few places been as yet ascertained. In the first place, of the great varieties to be found in cultivation, it would be necessary to select those which abound most in the products we chiefly require. The small Banana is most esteemed as a fruit by Europeans, and the people of Southern Asia, but the large-fruited and, in comparison with the other, coarse tasted Plantain is preferred by the natives of Northern India, as is the long yellow Plantain in Jamaica. Both of the latter abound in fibre, and are therefore to be preferred when both this and the fruit are objects of desire. The culture of the Plantain is, upon the whole, very simple, as it will succeed in almost any soil where the climate is warm and moist. The vicinity of water, for cleansing and washing the fibre, will, of course, be an essential. Professor Key, of Madras, has stated that in India the Plantain will flourish in the poorest soil and near brackish water, and that its culture might be extended with very little trouble and expense. A sucker being planted, rapidly attains maturity; some varieties in eight months, others within the year. Each producing a bunch of fruit which may weigh from twenty-five to forty, and even ninety pounds ; and each throwing out from its roots and around its stem, from six and seven to eight and ten fresh suckers. These will each form a distinct plant, producing its own bunch of fruit ; all requiring to be cut down annually in order to make room for the fresh suckers which spring up. This may go on for fifteen or twenty years, though some think that is better to renew the plantation entirely or partially at shorter periods. A chief consideration is the distance at which the original plants should be placed, in order to give room for the secondary suckers, as well as to allow of free ventilation. Some place them at distances of six feet, but it is bet-

ter to have them ten feet apart, either around the boundaries of fields or of gardens, or in rows as a separate plantation. In the latter case, it is recommended that there should be space enough between the rows to allow of the culture of other crops. In some parts of India, the Plantain is employed as a nurse, or to afford shade, to the Betel Vine (itself one of the most valuable of crops), or to young Areca-nut and to Cocoa-nut Palms. By cutting away some of the suckers as they arise at different periods, and allowing others to remain, a supply of fruit, and also of stems for fibre, may be obtained for a great part of the year. In Demerara and Guiana, the Plantains have been injured by some disease, which has impaired their fruitfulness, and consequently, the profits of their culture. It has been recommended to plant them at sufficient distances (as eight feet) to allow of free ventilation, accompanied with good tillage in the intervals and the cultivation of annual crops of Maize, Yams, Sugar-cane, or Eddoes. (Arum.) According to the distances, there may be from 360 to upwards of 400 plants in an acre, each producing, say, on an average, seven suckers; making in all from 3100 to 3200 plants in an acre.

Preservation of the Fruit.—The fruit of the Plantain, when ripe, containing a sufficient proportion of nutritive matter may well serve as a portion of the food of the natives of warm countries. But it is probably as much employed by them before being perfectly ripe, as it is sometimes stewed, and at other times fried; and, by the natives of India, dressed in various ways to eat with rice. In the West Indies, the fresh Plantain, when boiled whole, forms a mass of considerable toughness, and which, when beaten in a mortar, constitutes the *foo-foo* of the negroes. (Simmonds.) When nearly or perfectly ripe, it is pleasantly, or even lusciously sweet, and it is in the former state that it is preserved. Col. Colquhoun describes the mode of preparation as very simple: "The fruit is gathered when fully ripe, and is laid on light cane frames, exposed to the sun. When it begins to shrivel, the outer skin is stripped off. This is stated to be a very essential part of the process, as without it the fruit acquires an unpleasant flavour. After this, the drying is completed. During this process it becomes covered with a white, mealy efflorescence of sugar, as the fig does under similar circumstances. For convenience of transport it is pressed into masses of about 75 lb. each, and is wrapped in plantain leaves. The masses are twenty-four inches long by fourteen wide, and four inches thick. The samples presented to the Society of Arts were about two years old, sufficiently moist, of a consistence and flavour between the date and the fig, very sweet, and without any acidity. It is evident that this process of preservation will be found to be of considerable value in other parts of the world, and especially in situations where it is cultivated in larger quantities than the fruit can be consumed. The drying in the sun would be sufficient in dry climates, but baking in ovens seems to be necessary in moist climates, such as Dacca and Jessore. The process seems to be sufficiently well understood in several parts of India. When the fruit is of a good kind, no addition of sugar can be necessary. This subject seemed so worthy of a fair trial in the British West Indies to the Society of Arts, that they offered, in the year 1834, a premium for its encouragement. It seems no less important for the East Indies, especially if any planters should be induced to cultivate the Plantain in large quantities, on account of its fibre, or for the preparation of half-stuff for paper-makers.

Plantain Meal.—Mr. Simmonds describes this meal as prepared by stripping off the husk of the fruit, slicing the core, and drying it in the sun. When thoroughly dry it is powdered and sifted. It is known among the creoles of the West Indies under the name of *Conquin tay*. It has a fragrant odour, which it acquires when drying, and which somewhat resembles that of fresh hay or tea. The flavour of the meal is, moreover, said to depend a good deal on the rapidity with which the slices are dried. Hence, the operation is only fitted for dry weather, unless where a kiln or stove is had recourse to. Above all, the Plantain must not be allowed to approach too closely to yellowness or ripeness, otherwise it becomes impossible to dry it. The colour of the meal is, moreover, injured, when steel knives are used in husking or slicing; but nickel blades or Bamboo slicers would not injure the colour. On a large scale, some single machine might be adapted to the husking and slicing processes, and the mode tried by which arrow-root is obtained, by scraping and suspension in cold water. It is calculated that the fresh core will yield forty per cent. of dry meal, and that 5 lb. may be obtained from an average bunch of 25 lb. weight; and an acre of Plantain walk of average quality, producing even during the year 450 such bunches, would yield upwards of a ton of meal, the value of which must of course vary in different countries according to the price of other articles of food. In the West Indies it is largely employed as the food of infants, children, and convalescents. In point of nutritious value, we have seen that the fruit approaches the potato, and the meal to that of rice. There can be no doubt, therefore, of the value of this meal, and of the benefit of preparing it, wherever the fruit is produced in larger quantities than it can be consumed.

Preparation of the Fibre.—The Plantain has been stated to abound in fibre—indeed, almost, every part of the plant may be said to be availa-

ble for this product. It is related, that from the upper part of the spurious stems, spiral vessels may be pulled out in handfulls, and are used as tinder in the West Indies. De Candolle has described them as consisting, in Musa, of seven distinct fibres lying parallel, formed into bands; and La Chesnaye of upwards of twenty, arranged in a spiral manner. M. Mohl describes the secondary cell-membrane as divided into as many as twenty parallel spiral fibres. But these are not the fibres which are separated for economic purposes, nor are they situated on the same side of the vegetable structure. For instance, if we take any separate layer of the Plantain stem—that is, a part of the sheathing footstalk of a leaf—we may observe on its outer side a layer of strong longitudinal fibres, which form a kind of framework or ribs for the support of the structure, which is cellular on its inside. It is on this side that spiral vessels are placed, and next the pith in exogenous plants. They are abundant in the peduncle, or core, as it is often called, of the Musa. As in the Manilla, so in the common Plantain, the fibre is found to be coarse and strong in the outer layers of the sheathing footstalks, fine and silky in the interior, and of a middling quality in the intermediate layers. This fibre is separated by the natives of Dacca, for instance, and is used by them for making the string of the bow with which cotton is teazed (bowed). Much of it is well adapted for cordage. Mr. Leycester (*v. supra*), when calling attention to the fibre of the *Musa textilis* grown in Calcutta, directed attention to the fibres of *M. sapientum* and of *M. ornata*, as fitted to answer as string for all gardening purposes. Mr. Crawfurd is of opinion that the common Plantain most probably afforded the Indian Islands the principal material for their clothing, in the same way that the indegenous species does in the Philippine Islands. The art of making cloth from these fibres seems also to have been known in Madagascar. There is no doubt that the large cultivated Plantain of India contains a considerable quantity of strong fibre, in the same way that the common yellow Plantain does in Jamaica. But it seems well worthy of inquiry, whether the wild, and at present useless Plantains, growing along the foot of the Himalayas and on the Neilgherries, may not yield a stronger fibre than any of the cultivated kinds. The fibre may be easily separated from many parts, by simply scraping it on a stone or flat-board, with a piece of hard, wood; iron, though frequently used, no doubt injures the colour. In the following directions given by Dr. Hunter ('Art Journal,' Madras, i. pp. 108 and 376) the essentials are attended to, and the fibre is separated in an uninjured state, but the process is probably not the most economical. To prepare the fibres of the Plantain, he rejects the outer, withered layer of leaves, and then strips off the different layers, and proceeds to clean them in the shade, if possible soon after the plant has been cut down. Lay a leaf-stalk on a long flat board, with the inner surface uppermost, scrape the pulp off with a blunt piece of hoop-iron fixed in a groove in a long piece of wood. When the inner side, which has the thickest layer of pulp, has been cleaned, turn over the leaf and scrape the back of it. When a good bundle of fibres has been thus partially cleaned, it ought to be washed briskly in a large quantity of water, so as to get rid, as quickly as possible, of all the pulpy matter which may still adhere to the fibres. It may be readily separated by boiling the fibres in an alkaline ley or in alkaline soaps, but not in the Indian soaps made with quicklime, as these are too corrosive. When the fibres have been thoroughly washed, they should be spread out in thin layers or hung up in the wind to dry. If exposed to the sun when in a damp state, a brownish-yellow tinge is communicated, which cannot be easily removed by bleaching. Exposure during the night to the dew bleaches them, but it is at the expense of part of their strength. If we attend only to what is essential in the above process, we find that all that is required is scraping or pressure to separate the cellular and watery from the fibrous parts. This is followed by careful washing, and sometimes by boiling in an alkaline ley, but the latter part of the process does not appear to be essentially necessary. In the West Indies, according to the complete account of a practical correspondent in Jamaica, as given in Simmonds' 'Commercial Products of the Vegetable Kingdom,' the fibre is separated, either by crushing under rollers in a mill, or by fermentation. If by the latter process, there is considerable saving in carriage, as the stems, when cut down, are heaped together near where they have grown, and are shaded from the sun by laying the leaves over them. A drainage of the sap takes place, which is described as having a tanning property, and as discolouring the pieces which lie at the bottom. But several weeks elapse before decomposition is complete, when the fibres can be easily separated from the rest of the vegetable mass. There is little doubt, that besides discoloration, there must be some weakening of the fibre by this process, as we know takes place in India when the stems are steeped in water until some decomposition takes place. It is usual not to cut the stem until fruit has been produced; "for two reasons—first, that the fruit be not lost, and secondly, that the tree will not have arrived at its full growth and ordinary size, and the fibres will be too tender." This is the reverse of the practice in the Philippines, where the stem is cut before the fruit appears, in order to ensure a better quality of fibre. It would be an interesting experiment for those, favourably situated, to ascertain the mode by which the

best kind of fibre is produced, and what would be the loss of profit, supposing that the fruit is sacrificed for the sake of the fibre. The stem is described as being cut off about six inches above the ground, and being tender, it may, on being bent down, be cut asunder with a single stroke of a hatchet or cutlass. It is then divided, longitudinally, into four parts, the centre taken out and left to serve as manure, and the pieces conveyed at once to the mill to be crushed. It is said that "one man can cut down 800 trees, and split them in a day." A very convenient size for the rollers of the mill, will be found to be about three feet in length and one foot in diameter. In the process of crushing, care should be taken to separate the tender from the harder layers of fibre. This may be attained by having the rollers of the mill placed horizontally; and if the pieces of Plantain are passed lengthways through the mill the pressure will be uniform, and the fibre uninjured. "In this manner, pass the different sorts of layers separately, and the produce will be about four pounds of fibre from each tree. The stalks of the branches of the Plantain (no doubt the midrib of the leaf is meant) give the best fibre, and a large quantity as compared with the body of the trees; 100 lbs. of the stalk will give 15lb. nett of fibre. In general, if a tree will give 4lb. nett of fibre, the stalks will give 1lb. out of the 4lb. The stalks ought also to be crushed separately, because they are harder than the exterior layers of the tree. About 3000 trees may be passed through the mill in a day. Whilst the experiments were in progress, it was ascertained that, with a single horse, 100 Plantain trees, on an average, were crushed in twenty minutes—giving five minutes' rest for the horse." The quantity of produce from each plant, is the point of greatest discrepancy between the West Indian practice and Dr. Hunter's experiments, as he mentions only a few ounces of fibre as procurable from each plant. But as he rejected the outer parts, and did not include the midrib of the leaves, the discrepancy may be partly accounted for. The combings or tow, separated from the fibres during their preparation, are also of value as a substitute for horse-hair, for stuffing mattresses, &c.; and also the peduncle or core, if pounded into half-stuff for paper-makers. Some of the cellular tissue containing much fibrous matter, might, probably, be converted to the same purposes. In addition to the above processes of crushing and washing, the West Indian account also gives the details of the process of boiling the fibre with carbonate of soda and quick-lime, in order, it is said, to get rid of the remaining vegetable matter, and to bleach the fibre. The different qualities of which, having been crushed separately, are of course to be kept so, and boiled separately. The proportions given in the above account are for making three tons of fibre per day. For this, four large (300-gallon) boilers are required, and about 360 lb. of soda would be consumed, with a proportionate quantity of lime; or the soda, that is its carbonate, may be first deprived of its carbonic acid. This may be done by preparing, in a small separate boiler, the quantity of liquid necessary for a day's consumption, which may be done in about an hour, by taking, by weight, ten parts of soda, six parts of quick-lime, and not less than seventy parts of water. The operation of boiling in the soda ley is said to be important in separating the gluten and colouring matter from the fibres, and also to facilitate their bleaching. The lightest coloured fibres do not require more than six hours to bleach, whilst the darkest will probably take from twelve to eighteen hours. It is advisable to place over each boiler the means of lifting the mass of fibre when boiled, and suffering it to drain into the boiler before it is carried away to be washed. The machinery necessary for cleansing and washing may be of various descriptions—as that used by paper-makers in England, or by coffee-planters and arrow-root growers in the West Indies. The fibre may be dried, by being hung over lines made of the same material. These, when dry, may be pressed and packed. For carrying on the culture of the Plantain on an extensive scale, in the West Indies, it is stated that the materials will cost £2000, buildings £500, purchase of land £1500, working capital £1000 to £5000. The estimated expense in cultivating one quarree or 5⅕ English acres, in Plantains, will be £30, as the work can be easily performed by one labourer in 300 days, at 2*s.* sterling per day. A quarree will produce 18 tons of mill-fibre, the cost of the preparation of which is as follows:

For workmen's wages, soda, lime, and fuel, at £3 per ton	£54
Freight to Europe, at £4 per ton	72
Manager	30
Duty, insurance, office fees, &c., at £1 per ton	18
	£174

Thus making the total expense of producing 18 tons of fibre £174, or £9 13*s.* 4*d.* per ton. By another statement, derived from different data, but somewhat similar sources, it has been calculated that Plantain fibre, in a coarse state, might be laid down in England, at £10 6*s.* 8*d.* But some expense would be incurred in cleansing the fibre for finer purposes. In another account, also taken from West Indian information, it is stated that the cost of well cleaned fibre would amount to £7 1*s.* 3*d.*, to which, of course, freight would have to be added, while half-stuff for paper-makers might, at the same time, be produced from the refuse at about half that sum. As Plantain fibre has not yet, as far as we have heard, been systematically prepared as an article of commerce, these calculations of cost are somewhat conjectural. But they are interesting, as showing, from the experiments which had been made, that large quantities of a valuable product

may be obtained at a comparatively cheap rate; and this, from what is now a complete refuse—that is, the stem and leaves; while the expenses of culture are paid for by the fruit. And the more so, as the data are West Indian, where the prices of material and the wages of labour are much higher than in India. Specimens of Plantain fibre, and a barrel of it for experimental purposes, were sent by two Exhibitors from Demerara, also some from Porto Rico (*v.* 'Illust. Cat., p. 982); and it was stated that the fibre might be obtained in very large quantities from the Plantain cultivation of the former colony. It is calculated that upwards of 600lb. weight of fibre might be produced annually from each acre of Plantains, after reaping the fruit crops. It is further stated, that "at present, the stems of the Plantain trees, when cut down, are allowed to rot on the ground. If a remunerative price could be realised for this fibre, a new branch of industry would be opened up to the colonists." India, unfortunately, furnishes no statements showing the rates at which Plantain fibre, tow, and pulp, might be obtained as articles of commerce. Dr. Hunter, of Madras, has done much in showing the various purposes to which this valuable product might be applied; as he sent to the Exhibition of 1851 both the fibre and the tow in a well-cleaned state. The former about four feet in length, and also dyed of several colours, as well as twisted into fine cord and into rope. Some Plantain rope was, moreover, sent in a tarred state. A portion of the tow sent in a state fit for packing and stuffing, and some converted into paper; of the latter, some was almost as thin as silver paper, and some of it seemingly as tough and tenacious as parchment, well fitted for packing paper, as apparently little affected by water. But in England some excellent letter paper has been made from the Plantain fibre. Besides the above, Plantain meal was sent by Professor Key from Madras, and preserved Plantains from Jessore. But dried Plantains seem already established as an article of commerce at Bombay, as we observe them among the exports for the year 1850-51, from thence to Cutch and Guzerat, to the extent of 267 cwt., valued at 1456 rupees. So that the various applications of which Plantain fruit and fibre are susceptible have been already made in India. It remains only to produce them as cheaply as the other products of the country. Dr. Hunter, in his experiments, found that the fibre cost about three annas, or about sixpence, a pound—which is prohibitive as an article of export. But he states that if regular supplies of the fibre were required, the price might be reduced to two annas. He also mentions that, at Madras, the rate at which the stems were at first supplied was ten annas for one hundred trees: but this was raised to four rupees for the same number, when he began to make use of them. This is sufficient proof that they are not very abundant there. But "in the vicinity of some of the Zillah (that is, of District) Jails, the Plantain is cultivated very extensively, but no use is made of the stems, which are allowed to rot on the surface of the ground." This is also the case in most parts of India. On the opposite coast of Arracan, the Plantain is abundant. What seem to be the layers forming the stem of such a plant, and about seven feet in length, are sold there in a dried state, and called *Pa-tha-you Shaw*; some of it even twisted into a bast-rope, is sold for the same sum, that is, for one rupee the maund or for about three shillings per cwt. As the above Shaw or *bast* of an unknown plant is sold at so cheap a rate, as well as the other basts sent from Arracan to the Exhibition of 1851, even after some preparation, there is no reason why Plantain fibre might not be sent cheaply into market; and no doubt that it would very soon command a price equal to its real value, as a material for paper-making, for cordage, or for textile fabrics. The fibre might be collected in situations where the plant is already cultivated, in gardens, or where it grows wild, and its stems not turned to any account. Or it might be cultivated in fields on its own account, either with or without other crops, such as Pan or *Piper Betle*, or Ginger, Turmeric, &c. The fruit in its fresh state, near towns, or in a preserved state, or converted into meal, ought to pay all the expenses of, and afford some profit on the culture. The stems and leaves would thus be obtained at a minimum of cost—that is, simply of carriage. Indeed, if the crushing mill were not of too cumbrous a nature, it might be brought into the vicinity of the field, in the same way that the natives of India construct a sugar-mill and boiler in the immediate vicinity of where the Date tree is grown or the Sugar-cane cultivated. A mill, consisting of the rollers of a sugar-mill or an enlarged churka, with an Archimedean screw, or with cog-wheels, or with bands, to which motion is given by bullocks, as practised in various parts of India, would probably be sufficiently effective, and certainly economical. The separation of the different qualities of fibre, with the washing, combing or heckling, and drying, might at first all be performed by hand, where labour is so cheap. If all the fibrous matter, or the combings or tow only, should be required for conversion into half-stuff for paper-makers, nothing is more effective, and at the same time so economical, as the Dhenkee of India. To this attention has been recently called by Mr. Henley ('Journ. of Soc. of Arts,' vol. ii, p. 486), and which, as he describes, "resembles in principle our European tilt hammer." "Its cost would be—erected in place—engineers, foundations, and all charges included—three shillings; and this charge supposes the more

than usually heavy machine employed for paper-making"! "The total wages for the preparation of 20 to 30 lb." of suitable material, "would amount to sevenpence-halfpenny." Mr. Henley adds, that "in the event of employing such fibres as the Plantain leaf stalk, a small pair of hard wood grooved rollers, such as they employ for squeezing sugar-cane, would be very useful. Their cost is two shillings." Dr. Royle having, in a Lecture before the Society of Arts, recommended the Plantain as likely to yield an abundant supply of material for paper-making, Mr. Henley observes: "From extensive cultivation of the Banana or Plantain, which surrounds almost every house, it is probable this material would form one of the first objects of attention by paper-material collectors; but from its coarse, stringy nature, it would be cheaper in the state of fibre than as half-stuff. This plant offers great advantages for our views generally, for it is truly in the position of refuse, inasmuch as it has already paid the charges of its cultivation by its products in fruit. The interior of the plant, or true flower-stem, is eaten as a vegetable by the natives; the lower part being perfectly mild, whilst the upper extremity, near the bunch of fruit, pours out, on cutting it across, a limpid fluid, which is very acrid and deleterious, and is a true substantive olive dye on cotton cloth, as indelible as marking ink, for which it may be substituted." With regard to the price at which such materials could be obtained, Mr. Henley says; "I am of opinion that contracts could be made, according to the ordinary usages of the country, at the rate of from one rupee eight annas, or three shillings, to two rupees eight annas, or five shillings, per maund of 82 lbs., deliverable at any central depot within a radius of twenty miles. These prices are equal to from about £4 4*s*. to £7 a ton; and that of these too, a lowest-priced material could be landed in London, paying all charges, for £13 4*s*., and the more expensive, which would include articles equal to linen rags, at £16 5*s*." Having already noticed the facility with which the species of Plantain may be cultivated in suitable climates, Dr. Royle mentions that he lately tasted some excellent fruit of *Musa Cavendishii*, grown in a Fernery on Putney Heath. He warns cultivators against planting the Plantain too close together; for though this may produce fineness of fibre, it will also diminish strength, and want of free ventilation may produce disease. For separating the fibre, it may be a question whether smooth or grooved cylinders will be best for so fleshy and moist a substance, but it is very necessary to remember that the pulp or the fibre must be thoroughly dried, in order that it may not undergo decomposition when in transit in the hold of a ship. Of the value of the Plantain fibre for paper-making, there can, he conceives, be no doubt. Some paper, though unbleached, but excellent as far as substance and tenacity are concerned, was sent from India by Dr. Hunter, in 1851. In the year 1846, Mr. May showed Dr. Royle some beautiful specimens of note and letter paper made from Plantain fibre. He was at that time anxious to establish a manufactory for Plantain paper in Calcutta, but subsequently went to one of the British colonies in South America; and a gentleman showed specimens of paper made from Plantain fibre in Demerara. Mr. Routledge subsequently made some excellent paper, both of a tough and of a fine quality, from the fibres of species of Musa—sheets of which he presented to Dr. Royle, who has lately seen specimens of similar paper in the hands of Mr. Sharp. Besides which, excellent paper has for some time been made from the refuse of or from worn-out Manilla rope. All which facts prove that an excellent material for paper-making may be had in inexhaustible supplies, whenever those chiefly interested choose to take the necessary measures for securing such a supply. As to the other uses to which Plantain fibre can be applied, Lieut. Col. Whinyates, Principal Commissary of Ordnance, in a letter to the Secretary to the Military Board at Madras, states that the Plantain oakum or tow sent by Dr. Hunter is "undoubtedly of a very superior description, and admirably adapted for packing. From the soft, elastic character of the fibre, he also conceives that it would be a desirable substitute for coir in stuffing hospital beddings, &c. But he fears that the supply is too limited, and the cost all too high, being at that time (October 29th, 1850) about three annas the pound." With respect to the strength of Plantain fibre, Dr. Royle states that in some experiments which he had made on Plantain fibre, some from Madras bore a weight of 190 lb., but the specimen from Singapore bore not less than 390 lb., while a salvage of Petersburgh Hemp, of the same length and weight, broke with 160 lb. A twelve-thread rope of Plantain fibre made in India broke with 864 lb., when a similar rope made of Pine apple fibre broke with 924 lb. Even from these experiments, it is evident that Plantain fibre possesses sufficient tenacity to be applicable to many, at least, of the ordinary purposes of cordage, as is very clearly shown by the experiments detailed in the following tabular statement. But it is probable that the plants grown in a moister climate than that of Madras will posess a greater degree of strength. The outer fibres may also be converted into a useful kind of coarse canvass, as has been done by Dr. Hunter; and the more delicate inner fibres most probably into finer fabrics, as is the case with those of the Abaca or *Musa textilis*; when equal care has been taken in the preparation and separation of the fibres, and there is some experience in weaving them.—*Royle, Fib. Plants.*

STATEMENT showing the comparative Strengths of the undermentioned Specimens of Rope, Cord, String, &c., made from the fibres of the Plantain, with Manilla Rope, as exemplified in a set of Experiments carried on at the Arsenal, Fort St. George, in July, 1850.

Number marked on label.	[illegible] ELLED.	Arsenal Numbers.	Description.	Circumference.	Length of Rope, &c., used	Weight required to break the Rope, &c. MUSA PARADISIACA.

(5501) MUSA SAPIENTUM. MUSACEÆ.

The Plantain.

Kilah, DUK. | Vallee-kai, TAL.

There are several varieties of the Banana cultivated in the Deccan,—the large red, the green, and the yellow. A small sort, which is supposed to be the real Banana of the West Indies, is perhaps the most luxuriant of the whole. The plants blossom at all seasons, and as soon as the drupe of fruit begins to ripen, which is known by some turning color, it is cut and hung up to ripen in the house. The plant will not bear again, and may be cut down (otherwise it will perish of itself,) when the surrounding shoots grow up and blossom as the former. The plants are generally grown in beds or clusters in a good rich soil, when fine fruit is almost the sure return. In transplanting the shoots, if two or three feet high, about one half is generally cut off ofthe common plantain the green fruit is used in curries; the natives use the extremities of the flower shoots, the heart of the stem, and that portion of it from which the roots proceed in their curries. This and the variety Musa Paradisiaca Banana, Valey is cultivated everywhere in Southern India. It yields a fine white silky fibre of considerable length, specifically lighter than Hemp, Flax and Aloe fibre by 1-4th or 1-5th and possessing considerable strength. There are numerous varieties of the Plantain, which yield fibres of different qualities, viz:

Rustaley, superior table plantain.
Poovaley, or small Guindy variety.
Payvaley, a pale ash colored sweet fruit.
Monden, 3 sided coarse fruit.
Shevaley, large red fruit.
Putchay Laden or long curved green fruit.

These varieties, as might be expected, yield fibres of very different quality. The only samples in which the different plants are noted, were those contributed by the South Arcot Local Committee, but they are not well cleaned. Very fine specimens of this fibre were contributed by the Local Committees of Masulipatam, Tanjore, Malabar, Canara, Nellore and Travancore. Very carefully prepared Plantain fibre, Hackled Do yarn, string, rope, tow and half stuff for paper were exhibited by the Madras School of Industrial Arts. The same fibre was exhibited from almost every district in the Presidency, and varies in shade and quality according to the method of cleaning that has been adopted. This plant has a particular tendency to rot and to become stiff, brittle and discoloured by steeping in the green state, and it has been ascertained by trial that the strength is in proportions to the cleanness of the fibre. If it has been well cleaned, and all the sap quickly removed, it bears immersion in water as well as most other fibres, and is about the same strength as Russian Hemp. The coarse large fruited plantains yield the strongest and thickest fibres, the smaller kinds yield fine fibres, suited for weaving, and if carefully prepared, these have a glossy appearance like silk. This gloss however can only be got by cleaning rapidly, and before the sap has time to stain the fibre, it is soon lost if the plant be steeped in water. By far thel greater number of specimens of Plantain fibre exhibited were discolored from steeping, and they had acquired a dull ash grey or brown color, which in this plant is always accompanied by stiffness and brittleness; one or two of the specimens are so brittle as to break when gently rubbed; others are harsh and stiff. Some well made rope, line, and string were exhibited by several of the Local Committees. A 2d Class Medal was awarded for the ropes from Mayaveram in Tanjore, these were clean, strong, silky and well laid up. A 2nd Class Medal was awarded to Mr. Thorpe for the cleanest and largest bundles of Plantain fibre, prepared in the Monegar Choultry. The Madura Local Committee exhibited fine specimens of fibre cleaned both by the quick process and by soaking, the latter have lost their gloss and are stiff and not so strong as the others. The Travancore Local Committee exhibits some excellent fibre and rope, the latter very carefully laid up but stiff from over twisting. This kind of rope ought not to be hard spun, as it becomes stiffer when wet and is liable to snap if it gets into a twist or knot, The Plantain fibre being one of the most abundant in India, has received this lengthened notice.—*M. E. J. R.*

(5502) MUSA TEXTILIS. MANILLA HEMP.

Among the various substitutes for hemp, few have hitherto attracted more attention than Manilla Hemp, and this as well from the elegance of its appearance, combined with the power of bearing great strains, as from being very durable, lighter, and also cheaper than Russian hemp. It has of late years been much employed for cordage of various kinds, especially where considerable strain is required, as in ropes for raising goods into warehouses or out of mines. Some yachts, as well as many American vessels, have the whole of their rigging composed of Manilla Hemp, and this cordage, when worn out, can be converted into an excellent quality of paper. The plant yielding this fibre in Eastern Asia, is extremely interesting, not only because it may easily be cultivated but because there are other species of the same genus which may be turned to the same useful account. The plant which yields Manilla Hemp is called *Abaca*. The natives distinguish several varieties of the Abaca.

1. *Abaca btava* (the wild Abaca), called *Agotai* by the Bicoles.

2. Mountain Abaca, the fibres of which only serve for making ropes, that are called *Agotog* and *Amoquid* in the Bicol language.

3. The *Sagig* of the Bisayas.

4. The *Laquis* of the Bisayas, by whom the fibres of the original Abaca are called Lamot.

Rumphius states that the Malay name is *Pissang utan*; that it is called in Amboyna, *Kula abbal*; in Ternate, *Fana*; and in Mindanao, *Coffo*, as also the cloth made from it. He distinguishes the Mindanao kind from that of Amboyna. by the natives of the Philippine Islands, who are said to apply the same name to its fibre. The plant is sometimes called a tree, but it is, in fact, only a large herbaceous plant, which belongs to the same genus, and is, in fact, a kind of plantain or banana, which is named *Musa textilis* by botanists. It was first called *Musa sylvestris* by Rumphius in his 'Herbarium Amboinense.' It was thought to be a variety of *M. troglodilarum* by Blanco, but called *Musa textilis* by Don Luis Nee, in a memoir which has been translated into English, and published in the 'Annals of Botany,' vol. i; where there may also be seen another memoir, which was sent in French to Sir Joseph Banks. These have been republished in the 'Transactions of the Agric. Soc. of India,' vol. viii, p. 7, together with a translation by Mr. Piddington, of Calcutta, of a notice by Father Blanco, in his 'Flora de las Filipinas.' In addition to these we have a notice in the first volume of the Trans. of the above Society, 1828, by Mr. Piddington himself, one of the gentlemen who escaped the massacre of the English at Amboyna. From these authors we learn that the Abaca is abundant in the volcanic region of the Philippine Islands, from Luzon, in the northern province of Camarines especially, to Mindanao; also in the neighbouring islands, even as far south as the Moluccа Islands, that is, in Gilolo. Hence this species may be stated to extend from the Equator to nearly 20° of north latitude. It may, therefore, very probably be easily cultivated in other countries, where there is some similarity of soil, and warmth with moisture of climate; as in India in the province of Travancore, and on the Malabar coast, also in that of Arracan, in Chittagong. Assam, in parts of Bengal, and in the northern Circars. This was one of the plants subjected to experiment by Dr. Roxburgh, in the beginning of the century. His specimens are still in the East India House. Mr. Leycester, one of the founders of the Agricultural Society of India, called the attention of its members to its fibres as early as the year 1822, when he presented the fibres of three species of Musa. These were *Musa sapientum*, *M. ornata*, and the present species, *M. textilis*. That of the latter he describes as having been formed from a coat stripped off about sunrise on that day, and having been brought into the house about ten o'clock, had received no further bleaching from the sun or in any other way; and that he had had some of it made into a neat cord, which was in no way inferior to English whipcord. He concludes his letter by congratulating the members on the fibre of their common overgrown plantains being sufficient for all the purposes of twine requires in their gardens. Some time after this was written we find it stated in the 'Proceedings of the Agricultural Committee of the Society,' 1st October, 1836, that "a row of the Musa plant, from which the China grass cloth is made, is in a flourishing condition." But, on 12th August, 1840, the Committee notice the favourable appearance of some plants of the Manilla hemp-tree (the abaca or *Musa textilis*.) *Musa textilis* is the *Abaca* of the natives of the Philippine Islands. It is found both in a wild and cultivated state, but the natural groves are considered as property. The fruit is green and hard, and of a disagreeable taste. Several villages formerly furnished yearly 1500 arobas each of the fibre, and others exported nearly as much cordage. With the produce of this plant, the natives of these villages pay their tribute, parish dues, purchase the necessaries of life, and clothe themselves. The Abaca is cut when about one year and a half old, just before its flowering or fructification is likely to appear, as afterwards the fibres are said to be weaker. If cut earlier, the fibres are said to be shorter and finer. It is cut near its roots and the leaves cut off just below their expansion. It is then slit open longitudinally, and the central peduncle separated from the sheathing layers of fibres, which are in fact the petioles of the leaves. Of these layers the outer are harder and stronger, and form the kind of fibre called *bandala*, which is employed in the fabrication of cordage. The inner layers consist of finer fibres, and yield what is called *lupis*, and used for weaving the *nipis* and other more delicate fabrics; while the intermediate layers are converted into what is called *tupoz*, of which are made webcloths and gauzes, four yards long, of different degrees of fineness. These are universally used as clothing. Some being so fine, that a garment may be enclosed in the hollow of the hand. Besides Pina fibre, fibres of "Jussi" and striped Jussi dresses were sent from Manilla to the Exhibition of 1851, and "Bijuco" fibre is mentioned. The plants yielding these fibres are not known. Mr. Bennett says, at Manilla there is an extensive manufacture of muslin and sinamaya or grass-cloth; as if, like in the notice at Calcutta, the Abaca was supposed to yield China grass. The stem-like mass consists of cellular tissue and fibres, with much thickish, watery fluid, which requires to be pressed out. The fibrous coats when stripped off, are left for a day in the shade to dry, and are then divided lengthwise into strips, three inches wide. Blanco says the petioles are stripped off one by one, and an incision is made across inside with a knife, to take off the bark which covers them. They are then scraped with an instrument made of bamboo, until only the fibres remain. Sometimes they require much pressing while be-

ing scraped. Blanco says the strips are placed beneath the cutting edge of a knife fixed in a long bamboo, which acts as a spring; and the Abaca being placed beneath the knife, is drawn through strongly by one end This must act as a scraper, but much of the Abaca is said to be spoiled. When sufficiently scraped, the bundle of fibres may be shaken into separate threads; sometimes they are washed, and then dried and picked—the finest being separated by the women with great dexterity. Those for cordage require no further preparation. Those for fine weaving are rendered soft and pliable by beating them with a wooden mallet, after having been made up into a bundle. They are then fastened to each other by "almost invisible knots"—but rather, have their ends gummed together, as in the case of the Pine-apple fibre—then wound into balls, and afterwards committed to the loom. Don Luis Nee describes the Abaca as being dressed like flax on a kind of heckle—a sort of saw which operates like the heckle (Blanco). Mr. Piddington describes it as a bamboo scraper, into the slit of which the Abaca is introduced, and which being dragged downwards, acts as a scraper on both sides. The stuffs, when woven, are soaked in warm water (lime-water, Blanco) for twenty-four hours, after which they are soaked in cold water, then put into rice water, and, lastly, washed as before—by which means they acquire lustre, softness, and a white colour. Some are also dyed, and take different colours (as blue and red). Others are embroidered. Few are imported into Europe, but seem often to be confounded with grass-cloth. These details have been given in order that the proper treatment may be followed if the plant is cultivated in India; or some of them may be applied to the other kinds of Musa cultivated in India - the fibres of some of which may have a portion of the properties of the Manilla Hemp as cordage. Mr. Piddington had no doubt that when the Manilla Hemp was better known, it would be more appreciated, especially if properly manufactured: the great defect of Manilla-made rope being its stiffness in rainy weather, arising from the coarseness of the yarns—not more than three being to a strand, which should have nine or twelve. This, Mr. Piddington had ascertained in a vessel commanded by himself, in which both kinds were used: and the latter (made by himself) was at all times as pliant as hemp. It bears tarring well, and he had known it used for lower rigging with success. In a subsequent volume of the 'Transactions,' in the year 1840, Mr. Stewart Mackenzie, then Governor of Ceylon, forwarded to the Agricultural Society of India. a specimen of Manilla rope, with a note from Mr. Higgs, Master-Attendant at Trincomalee. In this the latter observes, "that shortly after the arrival of the Melville in this country, in 1832, Sir John Gore procured rather a large supply of the different sizes (of Manilla rope) for the squadron, from seven inches to one inch. 'In that ship we made extensive use of it, reeving it on one side of the ship against Europe rope on the opposite side, and it is from a close observation of its merits, that I have formed the opinion of its being very superior to Europe rope in this country, particularly if this has been long in store here." Mr. Higgs regrets that the Manilla rope is not better laid; and observes that Capt. Naish, one of the oldest captains in the China trade, was in the habit of bringing the large rope from Manilla, and laying it up afresh at Bombay, and tarring the yarns; when it became excellent rope for shrouds. The price of Europe rope at the Naval Yard at Trincomalee, was then £2 7s. 3d. per cwt, while the price of the Manilla rope (without freight) was £1 12s., and it was one fifth lighter than Europe rope.—*Royle, p.* 69. Having seen the rate at which such materials may be imported, both from the East and the West Indies, it is desirable to have some idea of the prices which are likely to be realised for Plantain fibre or pulp, when introduced into the markets of Europe. Manilla Hemp, which has long been in demand both in America and in Europe, had a nett average price, for the ten years previous to 1852, £32 per ton. In part of the years 1844 and 1845, it sank as low as £22 to £25; and the consumption increased so much, that the price rose, in 1852, to £44 and £50 for the average kinds; but, independently of what was used for cordage and coarse purposes, there was a considerable consumption of the fine, white qualities, for which horse-hair had originally been used. In the rise which took place in April, 1854, Manilla Hemp was quoted at from 70s. to 76s. per cwt. Though common Plantain fibre is not possessed of the strength of Manilla Hemp, yet it is fitted for many of the ordinary purposes of cordage and canvass, and some of the fine kinds for textile fabrics of fine quality and lustre. In the communication from Demerara, already quoted, it is stated that "in 1846, a gentleman (probably Mr. May) visited this colony, and exhibited several specimens of cloth of a beautiful silky texture, and specimens of paper of superior quality, manufactured from the fibre of Plantains grown in the Jardin des Plantes." There is no doubt that some of the more delicate fibres of the interior might be used for such purposes; and for these, a high price would no doubt, be realised; and for the coarser, outer fibres, which are fit for cordage, at least £30, some say £35, a ton; while some of the superior tow would be a good substitute for horse-hair, for stuffing beds, &c.; and the different qualities of half-stuff producible from the combings, &c., of different parts of the plant, would produce half-stuff, at least equal in value to the rags which sell in ordinary times from 16s. to 20s. a cwt. But when its qualities

are better known, it probably would sell at still higher rates, as there would be no labour in sorting, and no loss of material in cleaning. Mr. Betts was induced in India, to attempt the preparation of the fibre, from seeing a remark in the 'London Price Current,' of Dec., 1839, that considerable supplies of a new sort of Hemp from the stalk of the Plantain tree had realised from 6*d.* to 8*d.* per lb.; and the Society of Arts were induced, as long since as the year 1762, from the apparent importance of the subject, to offer a premium for the production of this fibre (*v.* 'Jury Report,' p. 102). Therefore, even with the least sanguine expectations, and on the most moderate computations, there is every prospect of a certainty of demand, accompanied by remunerative prices. With this in view, we may conclude our observations on this subject, which may appear to occupy too much space, and to have been treated of too much in detail. But if properly considered, it cannot but appear of vast importance to the natives of tropical countries, and to planters and colonists abroad, to utilise so valuable and abundant a product, which is now allowed to run to waste, and of which, if they increase the cultivation, they will at once attain the two-fold object of multiplying the supply of food for the body, at the same time that they are increasing materials for diffusing information for the mind.—*Royle, Fib. Plants.* Musa textilis grows freely in Singapore.—*Royle Fib. p.* 377. This species of banana, is a native of the Philippine and of some of the more northerly of the Molucca Islands. On account of its filaments it is extensively cultivated in the first of these, particularly in the provinces of Camarines, and Albay in the great island of Luzon, and in several of the Bisaya Islands, a range lying south and east of it. The name abaca belongs to the Tagala and Bisaya tongues, but is not the generic name of the banana in either of them. By the Spaniards of the Philippines the plant is known under the name of arbol de canamo, or the hemp tree, from which no doubt, is derived our own commercial one for the filament "Manilla hemp." The abaca, like other bananas, is propagated easily by the suckers which spring up at the roots of the old plant when it dies. A measure of 5000 square yards of land will grow 1000 abaca plants. It grows to the height of 13 or 14 feet exclusive of the leaves. The fruit is small, of a disagreeable taste, and not edible. When it is about to form, the plant is cut down, and the stem being cut open longitudinally, is found to contain a great quantity of filaments of various thickness, and usually a couple of yards in length. These are extracted, hackled after the manner of flax, and then sorted. Some of the finest are as slender as a hair of the head, and these are reserved for the manufacture of cloth, while the coarser are appropiated for cordage from the smallest rope to a ship's cable. In the husbandry of the Philippines, the abaca is of more importance than cotton. When or how its culture came to be first introduced is not known. In his enumeration of the plants of the Philippines on their first discovery in 1521, Pigafetta does not include the abaca, although he mentions cotton and the esculent banana; but it is possible enough that so peculiar a production may have escaped his notice. Dampier, in his account of Mindano, where he resided for six months in 1686, not only mentions the textile banana, but gives an ample and accurate description of the mode of extracting the thread from the trunk. "As the fruit of this tree," says he, "is of great use for food, so is the body no less serviceable to make cloths, but this I never knew till I came to this island. The ordinary people of Mindano do wear no other cloth." After this follows the account of the process of extracting the fibres, which is well worth perusal. The Dutch have of late years introduced the culture of the abaca into the northern or volcanic peninsula of Celebes, where it seems to be indigenous, and with a fair prospect of success. There is a large exportation of abaca in the forms of raw hemp and cloth, but especially of cordage, from Manilla.—*Crawfurd, Dit. p.* 1.

(5503) MUSCARDINE, the name given to a disease to which silk-worms are subject, and which often causes great injury to those who cultivate these animals for the sake of their silk. This disease is attended with the development of a fungus belonging to the genus *Botrytis*, and has been named by Balsamo and Montagne *B. Bassiana*. This plant, which is characteristic of the disease, can be propagated by the introduction of spores into a healthy caterpillar. The result of the changes produced upon the blood and tissues of the animal is its death. This disease is much more common some years than others. It frequently spreads to other insects; and the caterpillars of other *Lepidotera* can be inoculated by the spores of the *Botrytis*. When once the disease has appeared there seems to be no means of checking it. The best mode of prevention is to take care that the caterpilllars are not over-crowded, and that they have a sufficient supply of fresh food. The predisposition to this disease amongst silk-worms seems to be brought on by the same causes as those which act upon the human system, and render it favourable to the attacks of epidemic diseases. (Robin, *Hist. des Vegetaux Parasites.*)

(5504) MUSCICAPIDÆ, *Flycatchers*, a family of insectivorous Birds, so named from their mode of taking their prey. Thus, M. Temminck states that the Flycatchers (Gobe-Mouches) feed entirely on flies and other winged insects, which they catch as they fly ('Manuel d'Ornithologie') and our countryman White says:—"There is one circumstance characteristic of this bird (the

Spotted Flycatcher, *Muscicapa grisola*) which seems to have escaped observation, and that is it takes its stand on the top of some stake or post whence it springs forth on its prey, catching a fly in the air, and hardly ever touching the ground, but returning still on the same stand for many times together." ('Nat. Hist. of Selborne.')

Eurylaimus.—Bill broader than the head; under mandible very thin, particularly at the base. Nostrils basal, transverse, oval; the aperture naked. First quill slihgtly second almost imperceptibly graduated. Tail short, rounded. *E. Javanicus* (*E. Horsfieldii*, Temm). Entire length eight inches. Head, sides of the neck, and the whole of the neck and body underneath violet, or rather vinous, varying in intensity. The part of the forehead around the bill nearly black. Upper part of the neck brown, darker towards the back, where the tint is sooty. Wings very deep blackish-brown above, more intense near the shoulder, and lighter towards the extremity. A yellow streak between the coverts and secondary quills. Wings beneath from the axillæ to the shoulder yellow, which borders the wing externally. Tail-coverts black at the base and yellow at the tips, so that the rump appears yellow, which is the colour at the vent. Two intermediate tail-feathers black, four next on each side black, with a white transverse band near the extremity. On the two external feathers the band is near the middle, and rather broader. Bill reddish-brown at the base, with both mandibles irregularly variegated, and striped towards the extremity; culmen yellowish; cutting-edges intensely black and shining. Tarsi and toes dusk-yellowish; claws brown, inclining to black. Dr. Horsfield is of opinion that from the observations of Sir Stamford Raffles, in the catalogue of a zoological collection made in the island of Sumatra under his direction, and communicated to the Linnæan Society, we can also in some measure determine the range of this genus: "It extends," continues the Doctor, "from Sumatra eastward to Singapura, and thence south to the eastern extremity of Java near the Straits of Baly, where I discovered it in the year 1806; since that period I have not met with it again. We are indebted to Sir Stamford Raffles for the following remarks on the first species:—'It frequents the banks of rivers and lakes, feeding on insects and worms. It builds its nest pendent from the branch of a tree or bush which overhangs the water.' I found it in Java, in one of the most distant and inaccessible parts covered with extensive forests and abounding with rivers and marshes." Dr. Horsfield placed the genus among the *Meropidæ* or *Syndyctylæ*.—*Eng. Cyc.*

(5504) MUSHROOM. [AGARIDUS; FUNGI.]

(5505) MUSHROOM.

Koodruttee, HIND.

Commonly found all over the country during and after the rains.—*Riddell.* A tribe of fungus plants (*Agaricus*), some species of which are used for pickling, in making catsup, and for using fresh. Many kinds are poisonous, and it is only by experience that the edible varieties can be distinguished.—*Faulkner.* Mushrooms are often seen in the Tenasserim bazar, and the Karens have names for sixty-four different species of mushrooms and the allied fungi. They distinguish the edible from the poisonous kinds, they say, by touching them with the lime that they eat with the betel. If the fungus turn red when touched, it is regarded as poisonous. But they are so careless or ignorant, that sickness and death often ensue after eating them.—*Mason.*

(5506) MUSICAL INSTRUMENTS, *both European and Native, form an article of import and of internal traffic.* The principal instruments of the Mahomedans are the Sectar: Moorchung; Duff; Thekree: Poonggee; Meerdung Munjeera: Ghuggree; Ghoongroo; Sarung D'hol; Soor; Shuhnall; Banka; Qurna; Tooree or Toortooree: Sunkh; Nugara; Dunka; D'hubboos: Tukkoray or Zer Bum: Khunjooree Dacera; Dubla Puk' hawuj; Tasa; Murfa, Been or Vina, Keenggree; Doroo; Munjeera Ghoongroo. Humor in folliculo præputii secretus, *London* Concretum Moschus dictum, *Dublin.* Inspissated secretion in the follicles of the prepuce, *Edinburgh*, of MOSCHUS MOSCHIFERUS, Linn. Musk. The Musk animal differs from common Ruminants in the absence of horns, and in having long canine teeth on each side of the upper jaw. It inhabits the mountainous regions of central Asia, extending from the Himalayas to the Altai mountains, and from these to China. Hence, as in the case of Rhubarb from the same regions, we have Russian, China, and Indian Musk. It is singular that the common Hindoo name of the Musk, and in the Himalayas that of the Musk animal, is *kustooree*, a name similar to Castoreum a substance which Musk so closely resembles in

nature. The name *musk* is no doubt derived from the Arabic *mishk* or *mooshk*, which is evidently the same word as the Sanscrit *mooshk*. This has been used as a perfume and as a medicine by Hindoos from very early times. It seems to have been adopted from Serapion, but it was previously mentioned by Ætius. The animal bears a close resemblance to the Deer tribe in shape and size. It is usually less than three feet in length, with the haunches somewhat more elevated than the shoulders. The want of horns and the projecting canines have already been mentioned. There are altogether 32 teeth : namely, 8 incisors in the lower jaw, 2 canines in the upper, and 24 molars. The canines are not met with in the female. The ears are long and narrow, and the tail very short. The fleece, which consists of strong, elastic, undulated hairs, varies in colour with the season, the age of the animal, and perhaps the place which it inhabits. The general colour is a deep iron-grey. The individual hairs are whitish near the root, and fawn-coloured or blackish towards the tip. The gestation of the female was quite unknown until Mr. Hodgson in Nepal ascertained that it was about 170 days. They are extremely timid, mild, and gentle in their nature. Found on the tops of difficultly-accessible and generally open mountains, usually in the neighbourhood of the snow, but coming nearer to the plains according to the inclemency of the seasons, springing from rock to rock with great agility. The Musk animal is particularly distinguished by the males secreting the remarkably strong smelling secretion called Musk, in a planoconvex oval, hairy bag, of which the orifice is situated just before the præputial orifice. The sac is flat, smooth, and naked above where it is applied, against the abdomen, convex, below, and hairy, composed of several coats. The musk is secreted by small gland-like bodies situated in little pits on the most internal of these coats. The quantity in each sac varies from 1½ to 3 drachms It is most abundant in the rutting season and when fresh is soft, and of a reddish brown colour When dried, and contained in its native sacs, i forms the Musk of commerce. The kinds known are the Chinese and Siberian ; the last is inferior in its fragrance to the other. The Chinese is probably from the same kind of cold and lofty region as the Himalayan. Some of this is imported into and apparently consumed in *India Rogle* Musk is in grains or lumps, soft and unctuous to the touch, of a reddish-brown colour, with a powerful, penetrating, and diffusive smell. It is usually adduced as an instance of the subtlety of the particles of matter. The taste is bitter, disagreeable, and somewhat acrid; readily inflammable. Rectified Spirit and ether are the best solvents of Musk. Analysed by different chemists, it has been found to contain a variety of principles, as Stearine, Elaine, Cholesterine, an Oily Acid combined with Ammonia, free Ammonia, various salts, and animal principles, as Albumen, &c., an odoriferous principle which seems particularly attached to the Ammonia. But the quantity and proportion of the constituents vary considerably, perhaps from the difficulty of obtaining specimens which have not been subjected either to abstractions or to additions. The hunters even are said to adulterate it, and if they do not the Chinese merchants do so. —*Royle.* Musk, then, is the unctuous secretion of a glandular pouch or sac,, situated in the skin of the abdomen of the musk-deer (*Moschus moschiferus*), an inhabitant of the great mountain range which belts the north of India and branches out into Sibeiria, Thibet and China. It is also found in the Altaic range near Lake Baikal, and in some other mountain ranges, but always on the borders of the line of perpetual snow. It is from the male only musk is produced and the secretion when dry is of a dark brown or black colour, and somewhat granular. Its taste is bitter, and its peculiar and penetrating odour is well known. It was formerly held in high repute as a medicine, and it is still so among eastern nations. The musk-deer is eagerly hunted for the sake of its costly perfume, which, however, is always much adulterated. Tavernier says that the odour of musk, when recent, is so powerful as to cause the blood to gush from the nose, and in this way he would account for the supposed adulteration of the article with dried blood. Chardin also says, "It is commonly believed that when the musk-sac is cut from the animal, so powerful is the odour it exhales, that the hunter is obliged to have his mouth and nose stopped with folds of linen, and that often in spite of this precaution the pungency of the odour is such as to produce so violent an hæmorrhage as to end in death. I have heard the same thing talked of by some Armenians who had been to Bootan, and I think it is true. The odour is so powerful in the East Indies that I could never support it ; and when I trafficked for musk, I always kept in the open air, with a handkerchief over my face, and at a distance from those who handled the sacs, referring them to my broker : and hence I knew by experience that this musk is very apt to give headaches, and is altogether insupportable when quite recent. I may add that no drug is so easily adulterated or more apt to be so." Tavernier states that at Patna he once bought 1,673 musk-bags weighing 2,557½ ounces, containing 452 ounces of pure musk.—*Tomlinson.* Two musk-deer, called "kosturah" by the mountaineers were seen by Dr. Hooker in East-Nepaul. The musk, which hangs in a pouch near the navel of the male, is a well-known object of traffic in Bengal. This creature ranges between 8000 and 13,000 feet, on the Himalaya, often scenting the air for many hundred yards. It is a pretty

grey animal, the size of a roebuck, and something resembling it, with coarse fur, short horns, and two projecting teeth from the upper jaw, said to be used in rooting up the aromatic herbs from which the Bhoteeas believe that it derives the odour of musk. This he much doubted because the animal never frequents those very lofty regions where the herbs supposed to provide the scent are found, nor had he ever seen signs of any having been so rooted up. The *Delphinium glaciale* smells strongly and disagreeably of musk, but it is one of the most alpine plants in the world, growing at an elevation of 17,000 feet far above the limits of the kosturah. The female and young male are very good eating, much better than any Indian venison he ever tasted, being sweet and tender. Mr. Hodgson once kept a female alive, but it was very wild, and continued so as long as Dr Hooker knew it. Two of his Lepchas gave chase to these animals, and fired many arrows in vain after them: these people are fond of carrying a bow, but are very poor shots.—*Hooker Him. Jour.* vol. 1. p. 269. This substance is an extremely odorous secretion, lodged in a bag which is attached and peculiar to the abdomen of the male Musk-Deer (*Moschus Moschiferus.*) The elevated regions frequented by the creature, its timidity, and speed in flight, render it very difficult to obtain the substance, while the high price borne by it offers great inducements to substitute other articles for that which is genuine. The musk-bag varies much in form, colour, size, and quality, circumstances which suggest the belief that it is procured either from two or more species of musk-animals, or that it has been obtained at different periods of the year, or from very differently-aged animals. In the very young animal the bag is quite empty, while in the old and feeble the musk is in small quantity and of inferior strength. It is said to be secreted in greatest abundance during the rutting season, and to have then its sensible qualities most developed. The secretion has a much stronger odour in the animal which inhabits Tibet and China than in that which frequents the more northern districts of Siberia. In the fresh state the musk has an extract like consistence and a reddish brown colour, with are odour so powerful that the huntsmen can scarcely endure it. This odour diminishes by drying, and the musk acquires a friable granular state, and a dark brownish colour. In Siberia the chase occurs in spring and summer. In Tibet the pursuit is restricted by the government to certain periods, and the bags which are obtained are stamped with the royal signet. In commerce two and occasionally three varieties of Musk are met with. The Tonquin, or Tibet Musk, occurs in small oblong rectangular boxes, lined with lead, and covered with paper or silk. Each bag, or pod, as it is termed, is wrapped in thin lube or red paper on which are marked some Chinese characters. Sometimes the bags are enveloped in a deep yellow brownish nearly transparent paper, which becomes brittle by time. The most distinctive mark of this sort of musk is, that it is slightly flattened, nearly round, and very rarely pear-shaped. The yellow or yellowish-brown hairs chiefly at the sides, are often cut, while those which remain in the centre are darker coloured, finer, and less bristly. Generally the hairs converge or point towards a small natural opening. The pods are mostly about two inches and a half long and one inch and three-quarters broad. The weight of different specimens varies considerably, some being merely 3 drachms 30 grains, others 9 drachms 47½ grains; the average is 6 drachms 12 grains. The average quantity of musk contained in the sacks is about 2½ drachms. By careful removal of the bag there remains the musk, which is solid, in grains of different sizes, adhering to each other, soft and unctuous to the feel, of a reddish-brown colour, like a clot of blood dried, having frequently a number of hairs intermixed, derived from the inner side of the orifice already described. The taste is bitterish, acrid, disagreeable, and somewhat astringent. The odour is strong, peculiar (musky), penetrating, very lasting, and extraordinarily diffusible. It is stated that a single grain can constantly fill the air of a larger apartment with a sensible impregnation for many years, without its weight being perceptibly diminished; and one part can communicate its odour to 3000 parts of an inodorous powder. It should be kept in glass-bottles, very closely stopped, and preserved in a place neither very dry nor too damp. By the analysis of Geizar and Reiman it appears to consist of—1, a peculiar volatile principle (which can exist in a free state); 2, ammonia; 3, a peculiar fixed uncrystallisable acid (these three are in undeterminable quantity); 4, stearine and oleine; 5, cholesterine; 6, a peculiar bitter resin; 7, osmazome, with several salts; 8, a mouldy like substance, in part combined wih ammonia, and numerous salts; 9, sand; 10, water, acid, &c., with some volatile odorous matter. It has not been ascertained upon what musk depends for its peculiar properties. It has been conjectured that a kind of putrefaction goes on which evolves the peculiar odour. Moisture seems to favour this, and musk which when dry yields little scent, becomes powerful when moistened. The odour is augmented by adding a few drops of the solution of subcarbonate of potass.

2. Kabardin, Russian or Siberian Musk, is either received through St. Petersburg, or, it is said, sent to China, and laid, for some time among the bags of genuine Tonquin Musk, to acquire the odour of the latter and then shipped to Europe. The pods of this sort are in general larger, more oval, more compressed, and the

margins often have large portions of the skin of the abdomen attached to them. The colour of the hairs is a dirty milk-white. The musk exhibits a more homogeneous and less granular appearance, having a much fainter odour and taste than the preceding kind. The odour is augmented by moisture, but is somewhat nauseous and disagreeable. The wood cuts show the difference of aspect of the two kinds. Musk is more soluble in water than in alcohol. Of 100 parts of genuine Tonquin Musk, boiling-water dissolves 90 parts, alcohol only 50. Of Kabardin Musk water dissolves only 50 per cent. It is likewise soluble in ether, acetic acid, and yolk of egg.

3. A very small kind of pod is sometimes met with, which is not flattened, but perfectly round: the hairs of a yellowish-brown colour. This is probably the musk-bag of the *Moschus Altaicus*. It is safest to purchase the musk out of the pod, as there is then less opportunity of adulteration. Infusion of genuine musk is not precipitated by a solution of bichloride of mercury (corrosive sublimate); but genuine musk is precipitated by nitric and other strong acids, by acetate of lead (sugar-of-lead), and infusion of galls. The musk-bags are used by perfumers to prepare Essence of Musk. An artificial musk is sometimes made with nitric acid and oil of amber.—*Eng. Cyc.*

(5508) MUSK OKRO, Musk Hibiscus Musk Plant Abelmoschus Moschatus.

Hubb-ul musk, Arab. | Kala-Kustoorie, Guz, Hind.
Kapu Kinaissa, Cyng. | Cattu Gasturi, Mal.

The seeds of the (*Hibiscus Abelmoschus*), a native of the East Indies and South America. They are brown, kidney-shaped, the size of hemp seed, slightly compressed, striated, with parallel streaks, and covered with points slightly hollowed. In smell and taste, these seeds resemble a mixture of musk and amber. They are much esteemed in India for their cordial, stomachic, and antispasmodic virtues. In a powdered state, they are used as an adjunct to coffee by the Arabs. *Faulkner*. One of the most gaudy flowering shrubs in the Tenasserim country is the musk plant, whose large yellow blossoms with blood colored eyes are sometimes seen bedecking European grounds, and whose seeds have been said to be an antidote to snake bites.—*Mason*.

(5509) MUSK-RATS TAILS, are the tails of the *Ondatra*, (Lacepede) the Musquash of North America, of which there are three varieties, the black, the pied and the white. The animals are hunted for their furs and upwards of one million of skins are imported into England annually for hat making: their tails are covered with a thin sleek coat of short hairs, have a pleasing odour of musk and are greatly prized in Russia and the Maldive Islands. Their abundance in the northern parts of Russia impress use with the belief that the animal also inhabited Siberia, The Musquash is easily tamed, soon becomes attached and is cleanly and playful.—*Nobis, Eng. Cyc.*

(5510) MUSK-ROOT, the root of a plan brought to England from Russia and Persia and known also by the name of Sumbul. This root exhales a powerful smell of musk, and has been used in medicine as a substitute for that substance. The plant yielding it is not known, but the root has the appearance of belonging to the natural order *Umbelliferæ*. Its tissues are full of starch.—*Eng. Cyc.*

(5511) MUSKA KA JHAR. Hind

(5512) MUSKITO, Mosquito.

Muchr, Hind. Tam. | Tel.

In a former work on China, 'A journey to the Tea Countries, Mr. Fortune noticed a curious subtance called "mosquito tobacco," or "mosquito physic," for it is known by both of these names, which he had met with for the first time when travelling in the western parts of the province of Chekiang on his way to the Bohea mountains and the great black-tea country of Woo-e-shan. He says, The day before the discovery was made had been very hot, and during the night such swarms of mosquitoes came that neither my servant nor myself had been allowed to close our eyes. I had no curtains with me, and looked forward with dread to many such sleepless nights during the journey. "Why don't you procure some mun-jung-ean?" said the boatmen to my servant Delighted to find there was some simple remedy, I sent on shore to the first village we passed, and procured some sticks of this invaluable substance. I found it answer the purpose admirably, and used it every night during the remainder of that journey whenever I happened to sleep, whether in boats, in temples, or in the common inns of the country.—*A Res. among the Chi. p.* 108. Years after, during this Traveller's residence in China, on inquiring as to its composition from a person, at first he was very communicative. He informed him the following articles were used: namely, the sawings of juniper or pine trees (pih heang fun, or sung shoo), artemisia-leaves reduced to powder (nai-hai) tobacco-leaves (ean fun), a small portion of arsenic (pe-za), and a mineral called nu-wang. With regard to the proportions of each, it appeared that, to thirty pounds of the pine or juniper sawings, about twenty of artemisia, five of tobacco, and a small quantity of arsenic were added. But ere we had come to this point my informant's jealousy had been aroused, and his statements were evidently not much to be depended upon. He now began to question me in return for the answers he had given. "What did I want this information for? if I wanted to buy the article he had it for sale, and it was cheap enough."—*A Res. among the Chi. p.* 111. From subsequent inquiries, he ascertained the composition to be Pine and juniper sawings, wormwood leaves, and tobacco-leaves, reduced to powder, a

small portion of nuwang and arsenic. Each article was well beaten up with water, then the whole mixed together, and in the form of a thick paste rolled on a slip of bamboo. On exposure to the air the substance dried quickly, and was then put away for sale. When finished the sticks are somewhat like the common joss-sticks of the country, or about the thickness and length of a light walking cane. Another substance, much cheaper than the last, is found in every town and village in the central and eastern provinces of the empire where I have been, and no doubt it is in use over the greater part of China. Long, narrow bags of paper—say half an inch in diameter and two feet long—are filled with the following substances, namely, the sawings of pine or juniper mixed with a small portion of nuwang and arsenic. The proportions are thirty pounds of sawings, two ounces of nu-wang, and one ounce of arsenic. This mixture is not made up in the form of a paste like the latter but simply well mixed, and then run into the bags in a dry state. Each bag being filled is closed at the mouth, and then coiled up like a rope and fastened in this position with a bit of thread. Many hundreds of these coils neatly done up and placed one above another, may be seen exposed for sale in shops during the hot season, when mosquitos are numerous. When about to be used, the thread which keeps the coil together is cut, then the coil is slightly loosened, so that its sides do not touch each other, for if this happened it would ignite at various parts and soon be consumed. The outer end is then lighted, and the whole is laid carefully down upon a bit of a board, when it goes on burning for the greater part of the night. One hundred of these little coils may be bought for a sum equivalent to three pence of our money, and two of them will suffice for a night in an ordinary sized room. A third substance cheaper than either of the above, is made of species of artemisia or wormwood (A. indica) which grows wild on every hill in this part of China. It is the same kind I have already noticed as forming one of the ingredients in the genuine mosquito tobacco, and is that which was used in taking the honey from the bees in the temple of Teinting. It is gathered and thoroughly dried, then twisted or plaited into ropes, in which condition it is fit for use. Although cheaper and consequently more in use amongst the poorer classes, than the other kinds, it is not so efficient and it gives out more smoke than is agreeable to a European.—*Ref. among the Chi.* p. 113.—See BANE, Mac Mosquito.

(5514) MUSLIN.

Neteldoek, DUT.	Mousseline, IT.
Mousseline, FR.	Kisiea, RUS.
Musselin, GER. GUZ.	Muselina, SP.
Muslin, ENG.	Sana Sella PEL.
Saila HIND.	

A fine cotton fabric, extensively manufactured at Manchester, Glasgow, in France, &c. There are a great variety of kinds and qualities, as, book-muslin, cambric-muslin, mull-muslins, &c. Formerly all muslins were made in the East, and Dacca in Bengal was formerly celebrated for "its webs of woven wind." The Dacca muslin manufacture, which once employed thousands of hands, is quite at an end, so that it was with great difficulty that the specimens of these fabrics sent to the Great Exhibition of 1851, were procured. The kind of cotton (which is very short in the staple) employed, is now hardly grown, and scarcely a loom exists which is fit for the finest fabrics. The jewellers still excel in gold and silver filagree.—*Hooker. Him. Jour. Vol.* II. *p.* 254. At the Madras Exhibition of 1855, the Cambric Muslin bleached and the Isree exhibited by Veeraboruna Kristnama Chetty were of a very superior quality and the Jury considered the Manufacturer entitled to a reward of a 2d Class Medal.—*M. E. J. R.* The most celebrated of Indian muslins was that of Dacca Cotton grown in the vicinity, the thread from which does not swell. Chicacole, Upada a few miles north of Cocanada formerly produced fine muslins and at present a strong muslin, generally checked, is procurable at Chicacole at 3 to 6 Rupees per piece of 8 yards, I have had it made to order of very good quality at 11 Rupees the piece. The famous Arnee Muslins, of which *Book* Muslins are an imitation, are prepared near and at Arnee in the Chingleput district: they sell according to quality from ? to ? the piece of ? yards ? inches broad.—*Rhode, M. S. S.*

(5515) MUSQUASH. Is the skin of the musk-rat, a diminutive species of beaver, which is largely used as a hatting fur.—*Waterston.*

(5516) MUSSÆNDA WALLICHII. A species of mussænda with corymbs of orange-colored flowers, and a single sepal expanded into a large white leaf, is not the least interesting shrub to the eye of the curious. In Calcutta an allied species is cultivated in the gardens, but its abundance in Tenasserim forests prevents its introduction into European gardens on this Coast.—*Mason.*

(5517) MUSTARD, BLACK. TETRADYNAMIA SILIQUOSA, Linn. Sinapis, L. Semina, L. Sinapi, E. D. Pulvis Seminum, D. Flour of the Seeds, E. Sinapis Nigra, *Linn.* Common Mustard consists of the flour of the seeds of the Black Mustard, though generally mixed with that procured from the seeds of the White Mustard, or Sinapis alba, and deprived of fixed oil by expression. Both species have been long used in medicine, being the *napu* of Hippocrates, and the Sinapi of the Romans. The Black Mustard is indigenous in almost every part of Europe. *Bot. Ch.* The root is thick and fleshy, the stem about 2 to 3 or 4 feet high, hispid below, with smooth round branches above. Lower leaves large, rough, lyrate, variously lobed and toothed; upper

ones narrow, lanceolate, smooth, dependent. Calyx yellowish, equal at base, spreading. Petals obovate, yellow, spreading. Silique small erect, or placed close to the stem, obtusely quadrangular, nearly even and smooth, tipped by a short quadrangular style, but without the proper, often seed bearing beak of the genus; the valves convex, with one straight dorsal nerve, and a few lateral anastomosing veins. Seeds numerous in a single row, small, round, blackish brown.—*Royle.* Fig. 41.—E. B. t. 96.

Sinapis arvensis, Charlock, or Wild Mustard, E. B. t. 1748, has its seeds sometimes substituted for the Black Mustard. It may be distinguished by the long sword-like beak of the pods, and by the valves being three nerved. The Black Mustard wanting these, has been removed to the genus Brassica by Koch and other botanists. The Mustard plant is officinal on account of its seeds, or rather of the flour of these seeds, so well known as a condiment by the name of Mustard. But Dr. Pereira learnt that the best flour of Mustard is prepared by crushing the seeds of both Black and white Mustard between rollers, and then pounding them in mortars, when they are twice sifted to yield *pure flour of mustard*. Dr. Christison's information confirms that of Dr. Pereira, that common flour of mustard is adulterated, partly on account of the pungency of Black Mustard seed. "Two bushels of black, and three of white seed yield, when ground, give 145 pounds of flour; which, to diminish the pungency and improve the colour, is mixed with 56 pounds of wheat flour and two pounds of turmeric; and the acrimony is restored without the pungency, by the addition of a pound of (capsicum) chilly pods, and half a pound of ginger." (c.) Dr. Thomson says he could detect no turmeric, nor cayenne pepper in the specimen which he examined. The *pure flour* of Mustard ought alone to be used officinally. Though Black and White Mustard have both been minutely examined by several chemists, they still require further investigation. The former contains a Fixed Oil, Gummy matter, Sugar, a colouring and a peculiar green matter, a Fatty pearly matter; *Myronic acid* in combination with Potash, or Myronate of Potash (the Sulpho-Sinapisin of Henry and Garot) *Myrosyne*, *Sinapisin*, and some salts.

Sinapis alba, Linn. E. White Mustard. The white Mustard is mentioned in the Edinburgh Pharmacopœia as well as the black (v. supra). It is, like the former species, indigenous in most parts of Europe, and may like it have been employed by the Greeks, as it possesses nearly the same properties. *Bot. Cl.* Root tapering, small. The stem 1—2 feet or more high, round, smooth, or slightly hairy. Leaves lyrate, irregularly lobed or pinnatifid, roughish, Sepals linear, green, horizontal. Flowers large, yellow. Silique hispid, spreading on nearly horizontal stalks, short, tumid or knotty from the prominent seeds, shorter than the sword shaped beak; valves with 5 straight strong nerves. Seeds few on each side, large and roundish, pale yellow coloured, having in the interior a yellow mass, which is covered by a thin pellicle of what must be composed of condensed mucilage. Fig. 42.—E. B. t. 1677. White Mustard seeds yield about 36 per cent. of fixed oil, and when macerated in water, a thick mucilaginous, almost insipid liquor, while Black Mustard seeds give little mucilage, but a pungent taste to the water. According to the analysis of John, these seeds contain.—1. An acrid volatile oil. 2. A yellow fixed oil. 3. Brown resin. 4. A very little extractive. 5. A little gum. 6. Lignin. 7. Albumen. 8. Phosphoric acid, and salts. White Mustard does not furnish volatile oil; but, in certain circumstances similar to those with Black Mustard seed, a fixed acrid principle is produced, which, like the volatile oil of Black Mustard, did not previously exist. The *fixed acrid principle* is an unctuous liquid of a reddish colour, without odour, but having a biting acrid taste, analogous to that of Horseradish root. It contains Sulphur. M. Faure states that this same principle is formed in small quantity when Black Mustard is treated with water. *Erucin* which does not redden the salts of Iron, and contains no Sulphur, is another principle found by Simon. *Tests.* As the common flour of Mustard is that usually employed, instead of the powder of Black, or the mixed powders of the Black and White Mustard, as in the E. P., so it often contains adulterations along with the true flour. But as Mustard flour is sometimes exhibited internally, it is desirable to have it in a pure form. The adulteration of wheat flour can be easily detected, by the test of the Edinburgh Pharmacopœia. "A decoction allowed to cool is not turned blue by tincture of Iodine." Mustard flour is weakened by the addition of wheat flour. A sinipism of mustard may be made with bread-crumb, or the Mustard flour may be spread on a poultice; vinegar is worse than useless, as like other acids, it prevents the formation of the acrid principle. Messrs. Trousseau and Pidoux found boiling water unnecessary, as a cold poultice produces the same effect as a hot one, but takes a little longer time to produce its effects. The volatile oil is a powerful rubefacient and vesicatory, in the proportion of 1 part to 20 of proof spirit.—*Royle.* Dr. Hassall tells us that the plants from which mustard is obtained are, Sinapis nigra or black, and Sinapis alba, or white mustard, they belong to the natural family Cruciferæ. The black mustard plant is distinguished by its seed vessels, which are smooth, and the colour of the seeds themselves, which are reddish or blackish brown. In the white mustard plant the vessels or pods are clothed with hairs which render them rough

and the seeds are yellow. The two species of mustard differ in properties as well as in botanical characters. The seeds of S. nigra are more pungent, than those of S. alba, but there are other differences. Analyses has detected in black mustard seed several distinct chemical compounds. Mirouic acid, Mirocyne, a volatile oil, and a fixed oil of mustard. Of the composition of white mustard we find the following account in Pereira's "Materia Medica." "Robiquet and Boutron (Journ. de Pharm, xvii. p., 179) however have proved, that white mustard contains neither volatile oil, nor any substance capable of producing it, but owes its activity to a non-volatile acrid substance, which does not pre exist in the seeds, but is readily formed in them under certain conditions. Another chemical peculiarity of white mustard is, that it contains sulpho-sinapisin. The young or seed leaves of white mustard are used for salad. In Britain, both species are indigenous and may commonly be seen in flower in the month of June in waste places and fields, in the brick fields in the neighbourhood of Nottinghill they grow in great quantities. McCulloch's Commercial Dictionary contains the following interesting particulars in relation to the growth &c., of mustard. It was formerly extensively cultivated in Durham, but it is now seldom seen in that county. At present it is principally raised in the neighbourhood of York and throughout other parts of the North Riding, and being manufactured in the city of York is afterwards sold under the name of Durham mustard. Two quarters an acre are reckoned a good crop. Mustard is of considerable importance in the materia medica, and is extensively used as a condiment. It was not however known in its present form at our tables till 1720. The seed had previously been merely pounded in a mortar and in that rude state separated from the integuments and prepared for use. But at the period referred to, it occurred to a woman of the name of Clements residing in Durham to grind the seed in a mill and to treat the meal in the same way that flour is treated. Her mustard was in consequence very superior and being approved by George I speedily came into general use. Mrs. Clements kept her secret for a considerable time and acquired a competent fortune. In Bengal and other eastern countries mustard is extensively cultivated as rape is in Europe for the purpose of yielding Oil."—*Barley survey of Durham, page* 147; *London's Encyclopeædia of Agriculture.* The subjoined particulars, in reference to the manufacture of mustard, as furnished by a manufacturer, are given by Pereira:—"The seeds of both black and white mustard are first crushed between rollers, and then pounded in mortars. The pounded seeds are then sifted. The residue in the sieve is called dressings, or siftings; what passes through is impure flour of mustard. The latter by a second sifting, yields pure flour of mustard, and a second quantity of dressings: by pressure, the dressings yield a fixed oil which is used for mixing with rape and other oils." Immense quantities of wheaten flour are employed in the adulteration of mustard, and many samples almost entirely consist of it. It has been stated that pea-flour is sometimes used: out of fifty samples of mustard which Hassall submitted to examination he had not met with a single instance of adulteration with any other farina than wheaten flour. *Adulteration with Turmeric powder.* Turmeric powder is the ground tuber of Curcuma longa one of the Zingiberaceæ, it is of a dark yellow colour and consists of large cells, some of these are loosely imbedded in a reticular tissue, but others, and these the majority, are quite free: they may be recognised with facility under the microscope by their size and bright yellow colour. When crushed, each cell is found to contain coloring matter as well as a number of starch granules resembling closely those of Curcuma arrow-root, already described and figured. On the application of iodine the cells become of a deep-blue, and with potash of a reddish colour. Although we have examined a large number of samples of mustard in no instance have we found turmeric powder to be absent. By some means or other probably by moisture and heat the turmeric powder is made to part with a portion of its colouring-matter to the flour which enters so largely into the composition of the mustard of the shops. Four qualities of mustard are supplied by the manufacturer. The first is called "second" it is usually of a bright yellow colour, but is thickly studded over with numerous black or reddish-black points: these are fragments of the husks of black mustard seed. The next quality is termed "fine," it also presents a considerable number of black specks, but fewer than in the former case. The third quality is called "superfine," it is spotted to a much less extent, although minute specks are still visible. The fourth, or best quality, is the "double-superfine," in this the eye can scarcely detect husk at all, although with the microscope, a little may still be discovered. These several qualities are vended to the public by a wholesale and retail establishment in the city of London at the following rates: "seconds," 5d.; "fine," 8d.; "superfine," 11d.; "double superfine," 1s. 2d., per lb. The qualities of the following samples varied much—from "second" to "double-superfine." The price also varied greatly—from 1s. to 2s. the pound, the ordinary charge made being 1s. and 1s. 4d. the pound. Dr. Hassall's inquiries showed,

1st. That genuine mustard, whatever be the price paid for it, is scarcely ever to be obtained.

2nd. That the whole of forty-two samples submitted to examination were adulterated.

3rd. That the adulteration practised, in every case, was the same in kind, varying only in de-

gree, and consisted in the admixture of genuine mustard with immense quantities of wheaten flour, highly coloured with turmeric.—*Food and its adulteration, p.* 123.

(5518) MUSTARD OIL. SINAPIS SPECIES.

Rai ka teil, GUZ. HIND.	Avaloe and Sarsava Noona, TEL.
Sarshapatailum, SANS.	
Kadaghoo yunney, TAM.	

An expressed oil, prepared from the seeds of different species of Sinapis, is used in the Northern parts of Hindostan, and in many parts of Malabar, for culinary purposes, in the same way that butter and ghee is on the Coromandel Coast.—*Ainslie.* Mustard oil has of late been exported from Bombay to England and France.—*Faulkner.* Five or six species of Sinapis are cultivated in all parts of India, for the sake of the valuable oil they yield: those most frequently seen are *S. glauca, toria* and *racemosa*. The seeds of the "sinapis alba" yields by expression 36 per cent of a bright yellow, pleasant tasted, edible oil, having a strong smell, and slight taste of mustard. The seeds of "sinapis nigra," yield only 28 per cent of an oil in all respects similar to the above. The average price of mustard seed in eighteen large stations, in all parts of the Madras Presidency, for the Quarter ending 31st October 1854 was Rs, 1 2 8 per maund of 25lbs., the maximum being Rs. 1 14 6 at Cannanore, and the minimum As. 10 5 at Nagpore. In Vizagapatam it costs Rs. 208 per Sicca garee. The oil is not exported, from Madras but the seeds have been shipped as follows:—

In the years	1847-48	.....Cwt.	5,828
,,	1848-49.	..... ,,	6,767
,,	1849-50.	..... ,,	9,435
,,	1850-51.	..... ,,	9,909
,,	1851-52.	..... ,,	3,636
,,	1852-53.	..... ,,	16,075

Uses.—This valuable oil, although seldom sold in the market, being made when required, is used in most parts of India in cookery, and is considered superior to all other oils for anointing the body, which it is supposed to invigorate. In medicine, it is sometimes given internally, but is more frequently applied as a rubefacient. At the Madras Exhibition of 1855, the following exhibitors contributed very good specimens, Mr. Kohlhoff of Tanjore, Madras Tariff, Trichinopoly Local Committee, and Rajahmundry Local Committee. Lieut. Hawkes, exhibited a complete and interesting series of oils and oil cake of common mustard, obtained from four different sorts of sinapis.—*M. E. J. R.*

(5519) MUSTARD SEED, BLACK.

Khirdal. ARAB.	Susavic, MAL.
Kidi-tsai, CHIN.	Sirshuff, PERS.
Gau-aba, CYNG.	Mostarda, PORT.
Mosterd, DUT.	Gortschiza, RUS.
Moutarde, FR.	Sirsoon, Rajika, SANS.
Muslert, GER.	Mostaza, SP.
Kalee Rai, GUZ. HIND.	Kadaghoo, TAM.
Mostarda, Senapa, IT.	Avaloo, TEL.
Sinapis nigra, LAT.	

Black mustard seeds are small and roundish. Externally they are beautifully veined, and of a reddish or blackish brown colour, though sometimes whitish. Internally they are yellow. They are inodorous, but have an acrid phagidenic taste. The black mustard is indigenous in almost every part of Europe.—*Pereira.* It is also grown in some parts of India, and has of late years been exported from Bombay to England and France.—*Faulkner.*

(5520) MUSTARD SEED, WHITE.

Safeid Rai GUZ. HIND.	Kalococo, TAM.
Sinap-Alba, LAT.	

This species differs only in the colour and size of the seeds, which are yellowish, and much larger than the black seed. The properties of the white are less energetic than those of the black. In other respects they agree altogether.—*O'Shaughnessy.*

(5521) MUSTARD-TREE. The plant referred to by this name in Scripture is, according to Dr. Royle, the *Salvadora Persica* of botanists. It is a native of the East Indies. [SALVADORA.]

(5522) MUSTELIDÆ, the Weasel Tribe, a family of Digitigrade Carnivorous Animals, of which the Common Weasel is the type. Among the Polecats of warm climates, Cuvier notices the Javanese Polecat (*Putorius nudipes*, F. Cuv.), the African Polecat *P. Africanus*. Desm.), the Striped Polecat of Madagascar (*P. striatus*, Cuv.), and the Cape Polecat (the Zorille of Buffon; *Viverra Zorilla* of Gmn.). The following is a list of the species of Asiatic *Mustelidæ* in the British Museum:—

Martes melanopus, the Japanese Sable. Japan.

M. flaviyula (Hodgson), the White-Cheeked Weasel. India.

Mustela Hodgsonii (Gray,) Hodgson's Weasel. India.

M. Cathia (Hodgson), the Cathia. Nepaul.

M. Horsfieldii (Gray), Horsfield's Weasel. India.

M. Subhemachalana, the Nepaul Weasel. Nepal.

Helictis moschata (Gray), the Helictis. China.

H. Nipalensis, the Nepaul Helictis. Nepaul.

Mydaus meliceps (F. Cuvier), the Stinkard, or Teledu. Java.

Arctonyx collaris (F. Cuvier), the Balisaur, or Sand-Bear. India.

Lutra Chinensis (Gray), the Chinese Otter. China and India.

L. aurobrunnea (Hodgson), the Golden-Brown Otter. Nepaul.

Aonyx leptonyx, the Wargul. India.—*Eng. Cyc.*

(5523) MUTILLA ANTIGUENSIS, Linn. Mutilla occidentalis seems to be a different kind of the former. Beer botie is a most beautiful scarlet velvet colored insect, about the size of a large pea, but flattish, it is commonly found in rainy weather, in Hindostan and at Lahore. These insects are officinal, and are kept by the druggists. The native doctors use them against

snake bites, and in colic of horses.—*Honigberger, p.* 444.

(5524) MUTHERIE, the Tamil name of a Ceylon-wood known in England by the name of satin-wood; by the Portuguese it is called Burutu. It is a handsome and valuable wood, and may be considered the most durable of any in Ceylon for general uses, provided it is seasoned in the shade: it may be converted into handsome furniture, &c. In consequence of its weight all trees are cut in lengths of from ten to twelve feet, for the purpose of getting it floated down the rivers from the forests, which is done in canoes. I am of opinion that it may be obtained from twenty-five to forty feet long, and the largest diameter thirty-six to forty inches. That which is in general brought to the dockyard is about fifteen feet long, and from eighteen to twenty-four inches in diameter, being cut to that size for the ease of conveyance.—*Edye. Ceylon.*

(5525) MUTKE KE PULLIE. Dolichos Fabæformis. Small Sabre Bean. This is grown the same as the larger sort.—*Riddell.*

(5526) MUTTI, ALSO MUDDI.

Chuncoa CAN. | Muttia, BUCK.

Mutti (or Muddie) is the Canarese name of a good timber tree, common in some of the woods of the Malabar coast, the ashes of the bark of which the Natives use to chew with betel like Chunam.—*Ainslie's Mat. Med. p.* 266.

(5227) MUTTY PAL, the resinoid exudation of "*Ailanthus malabaricus*" D. C., is a peculiar substance, first mentioned by Buchanan, who observed it in the Animalay Forests. It is exhibited from Cochin and Travancore, and is said to be used as incense.—*M. E. J. R.*

(5528) MYLABRIS. The ancients chiefly employed two species of *Mylabris*, one of which, the *Mylabris cichorii* (vern. *telini* HIND.) has been used for ages, and is so at present by the European and native physicians of India and China. The blistering flies of India are chiefly the Mylabris or Meloe cichorii, the Cantharis gigas, and the Cantharis violocea. The *Meloe* or *Mylabris cichorii* (Telini, *Hind.*) is common in the neighbourhood of Dacca, in the Hydrabad country, in Kurnool, and numerous other localities. Dr. Hunter published a good account of this article in the 5th vol. of the *Transactions of the Asiatic Society*, p. 216. The insect is about an inch long, and ⅓ broad; the elytre or wing coverts are marked with six cross stripes of deep blue and russet brown. The *Buprestis* of ancient writers is met with in the bazars under the name of the golden fly (*sonamukhi.*) The *Cantharis violacea* is often mixed with specimens of *Meloe* in the bazars. The Telini fly, if procured before the mites have commenced its destruction, yields on an average one-third more of cantharidin than the *Spanish fly* of the European shops. The blue fly is of uncertain strength; the Buprestis in all the specimens obtained, was quite inert.—A species of Meloe called the *M. trianthema*, from its being usually found on the plant named *Trianthema decandra* (biscopra, *Hind.*) was described by Dr. Fleming. A tincture, acetous tincture, plaster, and ointment of the Meloe cichorii are described in the Bengal Pharmacopeia. Some prejudice exists against the article on account of its alleged excessive severity of action. This is solely owing to the presence of a greater quantity of *Cantharidin* than that contained in the common fly. Diluting the tincture, and adding to the proportion of lard and wax in the plaster and ointment, perfectly assimilate the action of the indigenous and the imported insects.—*O'Shaughnessy, page* 684. At the Madras Exhibition of 1855, specimens of the Indian Blistering beetles, *Mylabris pustulata*, and *punctum* were exhibited by Monsieur Le Docteur Collas of Pondicherry. These were accompanied with a full and interesting report on their blistering properties printed in the "*Moniteur Officiel*" of 2d March 1855. The larger species is *Mylabris pustulata*, and the smaller is *Mylabris punctum*—Both insects are found in large quantities at certain seasons all over Southern India. On account of Dr. Collas' careful researches into the natural history of these beetles, as well as his interesting report, and successful experiments with this therapeutic agent, the Jury awarded him a 2d Class Medal. —*Royle, O'Shaughnessy*; *M. E. J. R.*

(5529) MYMENSING. *The District of Mymansing* can furnish specimens of the best *sunn* (Crotolaria Juncea) and the best *pât* or *jute* (Corchorus Olitorius) and *maestee pât*, (Hibiscus Cannabinus) grown in Bengal. The fibres of these plants which are so commonly used in that country for making twine, ropes, sails, screens, bags, and paper, are dressed and exported, in large quantities, from Serajegunge and other parts of this district of Bengal, to Calcutta for shipment to England. From this district there might also be obtained samples of oil seeds, as mustard, sesamum, rape and linseed. The two latter are of a superior quality and are now valuable exports to England.—*Taylor.*

(5530) MYOSOTIS (from μυς, a mouse, and ωτ, the crude form of οὖς, an ear), a genus of Plants belonging to the natural order *Boraginaceæ*. It has a 5-parted calyx; the corolla salver-shaped contorted in æstivation; the throat closed with scales, the limb 5-fid, obtuse; the stamens included, with filaments very short; the style simple; the nuts smooth, externally convex, keeled within attached by a minute lateral spot near their base. This genus is distinguished from all the other Boragineous genera by the possession of a contorted æstivation of the corolla. The species are annual or perennial, rough or smoothish plants, with blue flowers in terminal racemes, which are revolute before expansion. About 50 species have been described, which in-

habit the more temperate parts of Asia, Africa, and America, and are abundant in Europe. Eight species are found in Great Britain.—*Eng. Cyc.*

(5531) MYOSOTIS PALUSTRIS. Great Water Scorpion-Grass, or Forget-Me-Not, has the calyx open when in fruit, and shorter than the pedicel, with straight adpressed bristles; the teeth short, triangular; the limb of the corolla flat, longer than the tube; the lobes slightly emarginate; the pubescence of the stem spreading. It is a native throughout Europe, and also of Asia and North America. In Great Britain it is found in humid meadows, bogs, banks of rivers, rivulets, and ditches. This plant has a large bright blue corolla with a yellow eye. It is a beautiful plant, and when once seen will be seldom forgotten. It is probably on this account that it has obtained its common name Forget-Me-Not. Amongst the young it is regarded as emblematical of true affection. A variety is described with white flowers.—*Eng. Cyc.*

(5532) MYRICA. Fortune notices one repeatedly: It is (the Greek Μυρίκη), a genus of Plants the type of the natural order *Myricaceæ*. It has its flowers in catkins, which are composed of concave scales; 4 to 8 stamens. The fruit a 1-celled 1-seeded drupe, and no perianth. There are several species of this genus, which are shrubs or small trees --*Eng. Cyc.* Wight gives Myrica integrifolia, 766; and Nilagirica, 938. Fortune says, in China the *Yang mae*, appears to be a species of *Myrica*, allied to the Himalayan *M. sapida*, noticed by Frazer, Royle, and other writers. The Chinese variety is, however, much superior to the Indian. Indeed I believe the Chinese have both, but use the Indian one as a stock for grafting upon—*Fortune, page* 344. There is a very large plantation of this tree in Chusan, and the fruit was beginning to be brought to the market during my stay there. It was sold at a very cheap rate, and was considered a great luxury by the native.—*page* 345. I had frequently seen the trees of the *Yang-mae*, but never when in fruit, so I determined to visit one of the plantations. *page*—345. On the sides of these inland hills there were large quantities of the *Yang-mae*. The trees were bushy, round-headed, and from fifteen to twenty feet in height. They were at this time loaded with dark-red fruit, not unlike, at first sight, the fruit of England's Arbutus, although very differently formed and much larger. I observed two kinds, one with red fruit, and the other with fruit of a yellowish colour. The trees formed most striking objects on the hill side. —*Ibid. p.* 345. The "Yang-mae," a species of Myrica, was also met with on these hill-sides, and some grafted plants secured for India. These are now luxuriating in the north-west provinces. This fine fruit will no doubt succeed admirably in the Himalaya, for already there is a variety—far inferior indeed to the Chinese kind, but yet a plant requiring the same soil and temperature—common on these hills. It is the Kaiphul of the hill-tribes of India.—*Fortune' Residence.* Having been engaged in procuring some Yang-mae trees, which the Government of India was anxious to introduce to the Himalaya, I was somewhat better informed upon this subject than the learned Chinaman. I told him the fine variety of Yang-mae was grafted upon the wild kind, which the Chinese call the san or hill variety (Myrica sapida); and further I showed him some plants which I had just purchased: but all was of no use; he was "convinced against his will," and still firmly believes the Yang-mae is usually grafted on the pine.—*A Res. among the Chi. p.* 64.

(5533) MYRICA CERIFERA. Wax-Myrtle or Bay-Tree, has cuneate lanceolate leaves, sometimes entire, but more frequently toothed, particularly towards the end, somewhat pubescent, a little paler beneath, and generally twisted or revolute in their mode of growth; has a branching half-evergreen stem, from 1 to 12 feet high. The small flower is formed by a concave, rhomboidal scale, containing three or four pairs of roundish anthers, on a branched footstalk. The pistiliferous catkins which grow on a different shrub are less than half the size of the staminiferous ones, and consist of narrower scales, with each an ovate ovary, and two filiform styles. To these catkins succeed clusters or aggregations of small globular fruits, which are at first green, but finally become nearly white. They consist of a hard stony covering, which incloses a dicotyledonous seed. The hard covering is studded on its outside with small black grains, and over these is a coating of hard white wax, fitted to the grains and giving to the surface of the fruit a granulated appearance. This plant is a native of woods in the United States of America. The bark of the root of this plant is acid and astringent; in large doses it produces vomiting, accompanied by a burning sensation in the throat. It is used as a stimulant and astringent. The wax of the fruit is collected and purified, and used for many of the purposes for which bees'-wax and candles are employed. The wax has been occasionally used in pharmacy in the same way as common bees'-wax.—*Eng. Cyc.* The Candleberry Mystle abounds in the Bahama Islands. The shrub produces a small green berry, which, like the hog plum, puts out from the trunk and larger limbs. Much patient labor is required in gathering these berries, and from them is obtained a beautiful green wax, which burns very nearly, if not fully, as well as the spermaceti, or composition candles imported from abroad. Not long since Mr. Thos. B. Musgrove, of St. Salvador (or Cat Island), obtained about 80 lbs. of this wax, and made some excellent candles of it. The method of procuring this wax is by boiling the berries in a copper or brass vessel for some time. Iron pots

are found to darken and cloud the wax. The vessel after a sufficient time is taken from the fire, and when cool the hardened wax, floating on the top of the water, is skimmed off.

(5534) MYRICA CORDIFOLIA.—According to the experiments of M. Cadet and Dr. Bostock, myrtle wax differs in many respects from bees' wax. Specimens of it assume shades of a yellowish green color. Its smell is also different; myrtle wax, when fresh, emitting a fragrant balsamic odor. It has in part the unctuosity of bees'-wax, and somewhat of the brittleness of resin. Its specific gravity is greater, insomuch that it sinks in water, whereas bees'-wax floats upon it; and it is not so easily bleached to form white wax. The wax tree of Louisiana contains immense quantities of wax. Mr. Moodie ("Ten Years in South Africa") says,—"I occasionally employed my people, at spare times, in gathering wax berries that grow in great abundance upon small bushes in the sand hills, near the sea, and yield a substance partaking of the nature of wax and tallow, which is mixed with common tallow, and used by the colonists for making candles. The berry is about the size of a pea, and covered with a bluish powder. They are gathered by spreading a skin on the sand, and beating the bush with a stick. When a sufficient quantity of the berries are collected, they are boiled in a great quantity of water, and the wax is skimmed off as fast as it rises; the wax is then poured into flat vessels and allowed to cool, when it becomes hard and brittle, and has a metallic sound when struck. The cakes thus formed are of a deep green colour and are sold at the same price as tallow. The wild pigs devour these berries when they come in their way, and seem very fond of them." A good specimen of myrtle, or candleberry wax, accompanied by candles made from it in the crude unbleached state in New Brunswick, was shown at the Great Exhibition. At a meeting of the Central Board, at Cape Town, in March, 1853, the members voted about £300, to employ some 20 or 30 men, in gathering berries from the Downs, and making wax during the winter months, that is, from the beginning of May to the end of September. The wax fetches a good price in the Cape market. In the annual report of the Cape of Good Hope Agricultural Society, in May, 1853, a very fine sample of myrtle, or berry wax, grown on the Cape Flats, was exhibited by Mr. Feeny, Superintendent of the Road Plantation, by direction of the Commissioners of the Central Road Board, in different stages of purification, from green to white, as also some candles; and it being conceived by the meeting that this article might ultimately become one of considerable importance for purpose of export, a letter of thanks was addressed to Mr. Feeny; and Nathaniel Day, the constable who assisted him, was presented with the sum of £5, as a remuneration for his trouble in assisting to purify and prepare the wax. On reference to the juror's report on the Great Exhibition, it will be gratifying to find that the berry wax, forwarded by this Society, had attracted peculiar notice, and a prize medal been awarded for it; the following reference is therein made to it: "some fine specimens of myrtle or berry wax, from the Cape of Good Hope, are exhibited by J. Lindenberg, of Worcester. This is an excellent material for the manufacture of candles, when employed in conjunction with other solid fats. The jury awarded a prize medal for these specimens." The Committee suggested every possible attention being drawn to this subject, in which they are gratified to state, the Commissioners of the Central Road Board have evinced a readiness to co-operate, by offering to place at the Society's disposal the sum of £ 10 10s., "to be given as a premium for the best information respecting the wax berry plant, the soils and situations in which it is found to grow most luxuriantly: the best mode of propagating and cultivating it, of collecting the berries, and extracting and preparing the wax, &c." And from a letter received from the Secretary to the Central Road Board, it appears that the Board had authorised the shipment to England of 2,561 lbs. of the wax, by the *Queen of the South* in November last, which, from the account sales lately received from Messrs. J. R. Thomson and Co., realised as follows, viz.: —

4 cases weighing nett 856 lbs. a	8d.	£28	10	8

Simmonds.—Of the Myrica Cordifolia of the Cape, so long since as 1840, it was mentioned that the wax was used for candles.—*Loudon's Arboretum, page 612.*

(5535) MYRICA INTEGRIFOLIA. Roxburgh Fl. Ind. iii. p. 765, from the N. E. frontier, seems to be different from M. sapida, its

fruit is acid and used for pickling—*O'Shaughnessy, page* 611.

(5536) MYRICA NILAGIRICA. Wight. Icon, 938.

(5537) MYRICA SAPIDA. Wall. Tentam. Nipal. t. 45

Kuephul, HIND.

Himalayas from the Sutlege to Nipal, fruit agreeably flavoured. The same, or a nearly allied species, is found in China and Japan. The bark (Kuephul) is aromatic and stimulant, and a favourite native medicine.—*O'Shaughnessy.*

(5538) MYRICACE'Æ, *Gallworts*, are plants constituting a very small natural order of apetalous Exogens, with separate sexes. The most essential part of their character is expressed by Endlicher in the following terms:—"Flowers unisexual. Males—Bractlets, 2; calyx, 0. Females—Hypogynous scales from 2 to 6; ovary 1-celled, with 2 styles; ovule 1, erect, orthotropous; drupe 1-seeded; seed erect; embryo without albumen; radicle superior." In general, their flowers are arranged in a manner similar to those of *Betulaceæ* and *Salicaceæ*, with which latter however they seem to have no real affinity. From *Casuaraceæ* curious Australian trees, with jointed leafless stems, like those of *Equisetum*, they are only distinguished by their erect ovule and orthotropous seeds. They are common in the temperate parts of the world, especially in North America, and the Cape of Good Hope. The order embraces 3 genera and about 20 species. —*Eng. Cyc.*

(5539) MYRISTICA. a genus of Plants, the type of the order *Myristicaceæ*. The flowers are diœcious; calyx urceolate, 3-toothed; filaments of stamens monadelphous: anthers 6 to 10, connate; ovary simple; style, none; stigma 2-lobed; pericarp fleshy, 2-valved, 1-seeded, seed enveloped in a fleshy aril.—*Eng. Cyc.*

(5540) MYRISTICA CINEREA. MYRISTICACEÆ.

Sandikai marum, TAM.

A tall straight growing tree, usually with fine clean bole. Wood light coloured, close, even grained, apparently of fine quality.—*Wight.*

(5541) MYRISTICA MOSCHATA,

Jadikai, TAM.	Jowzulteib, ARAB.
Jawpull, DUK.	Booapala, MALAY.
Jaephall, HIND	Jatafala, SANS.
Jowzbewa, PERS.	Nutmeg tree,, ENG.

Myristica, L. E. Nux Moschata, D. Nuclei, L. D, Kernel of the Fruit, E. of Myristica officinalis, *Linn.* E. (*M. Moschata*, Thunb. L. D. Nutmegs, Macis Involucrum, D. (arillus) of the Nut. Mace. Adeps et Oleum, *Diœcia Monadelph. Linn.*

A diœcious tree, 20 to 25 feet high, a native of the Moluccas, especially of Banda.—*Ainslie's Mat. Med. p.* 264.—*O'Shaughnessy.* The Nutmeg-tree is about 25 to 30 feet high, with some resemblance to a Pear-tree. Leaves faintly aromatic, alternate, sub-bifarious with short petioles, oblong, somewhat obtuse at the base, acuminate, glabrous, above dark green paler beneath. *Male.*—Racemes axillary. Flowers small, yellowish, the pedicels of each supported by a minute bract. Calyx urceolate, 3-toothed, thick and fleshy, with short reddish pubescence. Filaments united into thick oblong and obtuse column. Anthers about 9, (5 pairs, *Roxb.*), linear-oblong, attached round the upper part of the filamentous column, 2-celled, free at their base, opening longitudinally. *Female.*—Peduncles usually solitary, axillary. Perianth much as in the male. Ovary ovate. Style short. Stigma 2-lobed, persistent. Fruit pyriform or nearly spherical, about the size of a peach. Pericarp fleshy, splitting from the apex into two equal, thick, fleshy, astringent valves and displaying the deep-orange or scarlet coloured *arillus* or *Mace*, which cut into many irregular denticulate stripes embraces the nut so tightly as to impress it with superficial furrows. Nut ovoid, attached by a large umbilicus to the bottom of the cell; its shell is hard, of a dark brownish black colour, and glossy, with its inner coat of light-brown colour, thin, but spongy closely investing the seed. *Seeds* or *Nutmeg* conform to the shell, and consisting chiefly of albumen, into with the inner coat of the shell dips deeply, giving it a variegated, brownish veined, or *ruminated* appearance; while fresh rather soft, juicy, and more fragrant than after being dried. Embryo at base of albumen erect, patelliform. Cotyledons 2. thick, fine shaped, margins irregularly cut, Plumule of 2 unequal lobes. Radicle inferior, hemi-spherical.—Roxburgh chiefly. Fl. Ind. iii. p. 844. Coram, Plant iii. t. 267. Nees von. E. 133. St. and Ch. 104.—*Royle. M. officinalis*, Linnæus (*M. Moschata*, Thunberg; *M. aromatica*, Roxburgh), is the Nutmeg Tree. This tree is a native of the Moluccas Islands, especially of Banda, but cultivated in Java, Sumatra, and elsewhere in the East, and lately in Cayenne and several of the West India Islands. It yields nutmegs and mace, the best of which are produced in the first-mentioned islands. The fruit is of the size and form of a peach, and, when ripe, the fleshy part separates into two nearly equal halves, exposing the kernel surrounded by an arillus, the former being the nutmeg, the latter the mace. The arillus is red when gathered; but being sprinkled with sea-water and dried it assumes an orange-yellow colour. It has a fatty shining appearance, yet is horny and brittle. The odour is strongly aromatic; the taste aromatic, but sharp and acrid. It contains both a fixed oil (in small quantity) and a volatile oil. One pound of mace yields by distillation one ounce of the latter. The former is not an article of European commerce, and what is termed the expressed oil of mace, is obtained from the nutmeg, and should bear

its name. An inferior mace is obtained from various species of *Myristica*, specially the *M. tomentosa* and *M. officinalis* (Martius), which is a Brazilian tree. The properties of mace are similar to those of the nutmeg. On the removal of the mace is seen the shell, of an oval or ovate shape, and of a dark-brown colour, in which is contained the seed or nut. This is closely invested by an inner shell or coat, which dips down into the substance of the albumen of the seed, and gives it the character which is termed ruminated. Two or three gatherings of the nutmegs are made in the year, generally in July and August, in December, and in April. The third period yields the best nutmegs. The collected nuts are dried in the sun, or by the heat of a moderate fire, till the shells split: they are then sorted and dipped in lime-water, to preserve them from the attacks of insects. The nuts are about an inch long, of the size of a hazel nut, but with a furrowed or sculptured surface. Those of good quality should be heavy each weighing, on an average, 90 grains. The internal aspect is marbled and of a fatty appearance. The substance is gray; but the veins, which are of a reddish-brown, consist of cellular tissue abounding in oil, and are the processes of the internal coat already mentioned. Odour agreeable, strongly aromatic. Taste warm, aromatic, oily. Besides the fixed oil, it contains a volatile oil, lighter than water, being of the specific gravity of 0·931-47, while a spurious, oil of nutmeg is only 0·871. By keeping, it deposits a stearopten, or muscat-camphor, called Myristicine. The solid or fixed oil consists of stearine and elaine, with a light portion of volatile oil intermixed. Both the fixed and volatile oils are used for medical purposes. Of the fixed, there are two varieties, the English and Dutch, of which the former is the better. It occurs in pieces, wrapped in leaves of the banana, weighing about three-quarters of a pound. When cut into it has a uniformly reddish yellow colour. The Dutch sort is in large pieces, wrapped sometimes in leaves, sometimes in paper, and of a lighter yellow colour. Both are frequently adulterated. The volatile oil is also mixed with purified oil of turpentine. Nutmegs are frequently either digested in alcohol or distilled to abstract the volatile oil, and then passed off as fresh. Such nutmegs are lighter, and when a hot needle is inserted do not give an oily coating to it. Old, worm-eaten, or wild nutmegs should be rejected. Genuine or cultivated nutmegs are called female, to distinguish them from the male or wild nutmegs, which are the produce either of the *M. Maschata*, var. *sphenocarpa*, or of *M. tomentosa* (Thunb.). These are longer, heavier (weighing generally 110 grains), and of inferior quality. They are more apt to cause narcotic symptoms, giddiness, &c., than the true sort. The coarse strong-smelling nutmegs from Santa Fe are from the *M. otoba*. Other species also yield nutmegs —as *M. spuria*, in the Philippines: *M. Madagascariensis* and *M. acuminata*, in Madagascar, and *M. Bicuiba*, in Brazil. Some nutmegs have little or no odour, as the *M. fatua*, but they nevertheless act powerfully on the system. *M. spuria* yields a crimson juice, which is employed in the Philippines as a substitute for dragon's blood. Nutmegs and mace, from the large quantity of volatile oil, are decidedly stimulant, and when used in abundance produce, by exciting the circulation, narcotic effects. In moderation they promote the appetite and assist digestion.—*Eng. Cyc.* This tree has been introduced into India from the Eastward. The fruit ripens in the rains: it is the size of a large plum, with a green covering, and upon being opened, discovers a net-work of a dark red color surrounding the nut, which has a most beautiful appearance: this is the spice known as mace. The first care of the cultivator is to select ripe nuts and to set them at the distance of a foot apart in a rich soil, merely covering them very lightly with mould. They are to be protected from the heat of the sun, occasionally weeded, and watered in dry weather every other day. The seedlings may be expected to appear in from thirty to sixty days, and when four feet high, the healthiest and most luxuriant, consisting of three or four varieties, are to be removed in the commencement of the rains to the plantation, previously cleared of trees and underwood by grubbing and burning their roots, and these placed in the holes dug for their reception at the distance of eighty feet from each other,—screening from the heat of the sun, and violence of the winds. They must be watered every other day in sultry weather; manured once a year during the rains, and protected from the sun until they obtain the age of five years. The nutmeg tree is monœcious as well as diœcious, but no means of discovering the sexes, before the period of inflorescence, is known. Upon an average, the nutmeg tree fruits at the age of seven years, and increases in produce till the fifteenth year, and is said to continue prolific for sixty or eighty years. Seven months in general elapse between the appearance of the blossom and the ripening of the fruit: and the produce of one bearing tree with another, under good cultivation, in the fifteenth year may be calculated at five pounds of nutmegs, and a pound and a quarter of mace. It bears all the year round, but more plentifully in some months than others, and generally yields more abundantly every other year. It is necessary that the roots of the trees during their growth should be kept well covered with mould, for they have a tendency to seek the surface. The growth of the lateral branches is to be alone encouraged, and all suckers, or dead and unproductive branches, are to be removed with the pruning knife, and the lower shoots lopped off, with the view of es-

tablishing an unimpeded circulation of air."—*Penang Gazette. Riddell.* MACE. The arillus or (Jawatri, *Hind.*) is thick, between horny and fleshy, much lacerated, folded and anastomosing towards the extremity, almost enveloping the nut; when fresh, brilliant scarlet, when dry, more horny, yellowish brown and brittle. The smell and taste of the arillus are peculiarly fragrant and agreeable. It softens, but does not dissolve in the mouth. Beneath the arillus is found a bony shell, which covers the almond or kernel; this shell is thin, hard, brittle, brown and shining above, pale grey within, insipid and inodorous and encloses the nutmeg of commerce. NUTMEG. The kernel, Jaephul, *Hind.* Jatiphali, *Sans.* (*nutmeg muscade*) is large, rounded, obtuse at both ends, the size of a small Myrobalan nut, smooth, marked with reticulated chinks, those transversely placed being less evident than the longitudinal; grey externally. In the chinks occurs a whitish powder, apparently chalk; internally the almond is traversed by branching, reddish, irregular greasy veins, giving it a marble appearance. The nut is hard, and easily cut, scraped, or grated, very inflammable, but the smoke is devoid of the fragrance of the acid. The odour of the nutmeg is most agreeably aromatic: its taste hot, and analogous to the smell. The nut readily divides under the teeth, and is partially soluble in the saliva. Nutmegs are much injured by time, becoming the prey of insects, which perforate them in every direction; sometimes good nutmegs are adulterated with others from which the valuable principles have been extracted by alcohol. Worm-eaten nuts are also fradulently repaired by the introduction of a paste of flour and nutmeg oil into the holes.—*O'Shaughnessy, p.* 535.

Essential Oil of Nutmegs.—White, lighter than water, acrid, pungent taste and very powerful nutmeg odour,—*O'Shaughnessy, p.* 535.

Fixed Oil, or Butter of Nutmegs.—This occurs in commerce (in Europe) in flattened masses, of square form, yellowish, solid, internally marbled, 50 parts containing about 50 of essential oil. This substance is much adulterated, particularly with suet, spermaceti, marrow, wax, the oil of the Moringa pterygosperma coloured with alkanet or *rocou*, &c. &c. The fixed oil is obtained by bruising the nutmegs into a paste, which is compressed in bags between hot metallic plates. Two kinds are found in commerce—one in small earthen pots, of mace colour, and very agreeable smell, is exported from the Moluccas to Holland chiefly; the second kind is obtained from Holland, occurs in flat cakes, is far inferior to the first, and is usually adulterated with spermaceti.—*O'Shaughnessy, p.* 535. The chief use of nutmegs is as a spice, and for the preparation of perfumes and scented soaps. The tree, according to Mr. Fee, was altogether unknown to the ancients, and Κωμακον of Theophrastus and the *Cinnamomum* of Pliny have been erroneously regarded as identical with this. Avicenna seems to have been the first who described it under the same "*Jauzboa.*" The tree itself however has only been identified clearly within the last few years. The nutmeg tree is chiefly cultivated in the Banda islands, but plantations are now numerous at the Mauritius, Bourbon, Cayenne, Martinique, and in the English possessions to the Eastward, especially in Province Wellesley of Penang—also in the Tinnevelly district of Southern India. The natives of the Moluccas gather the nutmeg fruit by the hand, strip off and reject the pulpy pericarp, detach the mace carefully, and expose it to the sun, which soon changes its blood-red colour to a light brown, it is then sprinkled with sea-water to render it flexible, and to preserve it. The nuts are first sun-dried, and then smoked, until the kernel rattles against the shell. This envelope is then broken, and the kernels dipped twice or thrice in lime water. They are then heaped together for two or three days, wiped, and packed in bales or barrels. The nutmegs thus prepared have been long termed, "female," or "cultivated," in commerce, to distinguish them from a kind named the "wild" or male, which is less esteemed, and seldom found in European trade.—*O'Shaughnessy, p.* 536.

(5542) MYRISTICA TOMENTOSA. "Male nutmeg tree" Also a native of the Moluccas. The fruit is larger than in the preceding species, downy, its substance fleshy, more solid, and firm. The kernels is covered by a hard shell provided with a pale arillus, the kernel is 1½ to 2 inches long, elliptical, the parenchyme devoid of marbling. Its odour is weak, flavour disagreeable. The mace of this nutmeg is distinguished from the true mace by being formed of three or four regular bands united at the summit. The chemical composition of the article is analogous to that of the true nutmeg, but the oils are so inferior in proportion, that the "male" nutmeg is but of little commercial value.—*O'Shaughnessy, p.* 537.

(5543) MYRISTIC OTOBA. *Syn.* VIROLA SEBIFERA, Lamarck. *Myristica sebifera.* In Santa Fe, also yields aromatic nuts. A large tree of Cayenne and Guiana, the seeds of which when boiled with water give out a large quantity of a fixed oil, used for making candles. An acrid juice also excudes from incisions in the bark, and is employed as a popular medicine.—*O'Shaughnessy, p.* 537.

(5544) MYRISTICACEÆ. NUTMEGS, a family of Plants belonging to the division of Diclinous Exogens. The species are tropical, fragrant, aromatic trees, with an astringent juice, alternate coriaceous simple leaves, without stipules, and dicecious flowers. Of the flowers, the males have monadelphous stamens; the females have a single 1-celled ovary, containing an erect seed; and both have for calyx a tubular coria-

ceans envelope, with from 2 to 4, usually 3, valvate teeth. Their fruit is a 2-valved succulent capsule, containing a single seed enveloped in an aril, and consisting of ruminated albumen, abounding in a powerful and agreeable aromatic secretion; the embryo is very small, and placed in a cavity at the base of the albumen. The order is nearly allied to *Anonaceæ*, from which however it differs very remarkably in the total want of a corolla, and in the reduction of the number of carples to one. To section it in the artificial division of Apetalous Exogens, as is usually done, is to violate every principle of natural cla-sification. The Nutmeg of the shops, which is the seed of *M. officinalis*, is the only product of the order employed officinally. Other species bear fruit that may be employed as a substitute, but they are all inferior to the real Oriental *Myristica*. This order embraces 5 genera and about 35 species. The genera are, *Myristica*, *Virola*, *Knema*, *Pyrrhosa*, and *Hyalostemma*: *Virola sebifera* yields a fatty oil on being heated. *Pyrrhosa tingens* yields a crimson dye, with which the natives of Amboyna stain their teeth.—*Eng. Cyc.*

(5545) MYRRH. Myrrha, Gummi Resina, Balsamodendron (Protium) Myrrha, *Nees.* L. E. Myrrh. Octand. Monog. Linn.

Murr, Arab.	Myrrha, Lat.
Madu, Bali.	Manisan lebah, Mal.
Mirrhe, Dut.	Mirra, Port.
Myrrhe, Fr.	Vola, Sans.
Myrrhen, Ger.	Valatipolum. Palendra-bolum, Villeybolum, Tam.
Herabole, Guz. & Hind.	Bolinturaboluin, Tel.
Mirra, It.	
Madu, Jav.	

Myrrh is first mentioned in Exod. xxx. 23, by the name of *Mor* or *Mur*. The Arabic name also is *Mur*. The Greeks called it μυρρα, and also Σμυρνα. Herodotus mentions it as produced in the South with Frankincense, &c. Dioscorides states the variety called *Trogodytica* to be the best. In the Periplus of the Red Sea, Arrian mentions Myrrh with Olibanum as exported from the coast of Barbaria, that is, the modern Berbera. Bruce learnt that it was produced, as well as Frankincense, in the country behind Azab, or in that of the Dankali. The embassy to Abyssinia under Major Harris met with it on the hills in the comparatively flat country which extends from Abyssinia to the Red Sea near the Straits of Bab-el-Mandeb, or from the Doomi Valley to the banks of the Hawash. Mr. Johnston (Trav. i. p. 249) met with it in nearly the same locality. Both authors describe the Myrrh as exuding from wounds made in the bark, and that it is collected in January and March (H.), but chiefly in July and August, and in small quantities at other times of the year (J.); and exchanged for Tobacco with the merchants who proceed to Berbera, &c., whence it is exported to the coast of Arabia. Dr. Malcolmson wrote to Dr. Royle from Aden, that it is exported in native boats from different ports in the Red Sea, but chiefly from Berbera, Zela, and Massowah, and adds "there is no Myrrh produced in Arabia." Myrrh, it is well known, now reaches Europe chiefly from Bombay, having been imported from the Arabian and Persian Gulfs. It used formerly to be obtained also from Turkey. Some Myrrh, however, appears to be produced in Arabia, as Ehrenberg and Hemrich found a small tree in Arabia near Gison, on the borders of Arabia Felix, from off which they collected some very fine Myrrh. There is still considerable uncertainty respecting the plant or plants which yield Myrrh, though it is probable they all belong to the genus Balsamodendron.

Balsamodendron Kunth.—Amyris. Protium. *Wight and Arnott.* Flowers often unisexual. Calyx 4-toothed, persistent. Petals 4, linear, oblong, induplicately valvate in æstivation. Stamens 8, inserted like the petals under the margin of the annular disk or torus, which is cup-shaped, fleshy, deeply cernated. Ovary 2-celled. Style short, obtuse, 4-lobed. Drupe globose or ovate, nut thick and very hard, bony, 2-celled, (one of the cells by abortion, often obliterated,) cells one-seeded Balsum producing trees. Leaves with 3 to 5 sessile leaflets, which are without dots.

Balsamondendron Gileadense, K. Unarmed. Leaves palmately 3-foliolate, petiolate, smooth; leaflets obovate, oblong, very entire, glabrous; pedicels short, single-flowered, with the calyx broad, shallow, and campanulate.—This includes the *Amyris Opobalsamum* of Forskal; but fresh specimens and recent observations are required to distinguish whether this is different from the *Balessan* of Bruce. Other species which are found in the Peninsula of India and are *spinescent*, used to be included under it, but are considered distinct by Dr. Arnott, who does not now unite them with *Protium* (as in the Prod. Fl. Ind. Penins.) from which indeed they differ much in habit.

The *Balessan* of Bruce was found by him at Azab, and said to extend to the straits of Bab-el-Mandeb. Gerloch found it at Bederhunin, a village between Mecca and Medina. Forskal found his Opobalsamum at Haes in Arabia Felix. At Aden it is called Beshan. Dr. Roth, in the Appendix to Harris' Abyssinia (ii. p. 144) mentions B. Opobalsamum as occuring in the Adel country and the jungles of the Hawash, along with the Myrrh tree. The bark when wounded exudes the fragrant and far-famed Balsam which has been called Balm of Gilead, but which seems to have been only cultivated in Palestine near the town of Jericho. It is now never obtainable in Europe in a pure state, and therefore seldom if ever employed medicinally, though it is no doubt possessed of stimulant properties.

Balsamodendron Myrrha (fig. 56.) Stem shrubby, arborescent; branches squarrose, spinescent Leaves ternate; leaflets obovate obtuse, obtusely tooth-letted at the apex, the lateral smooth. Fruit acuminate (Nees). Bark pale ash-gray, approaching white. Wood yellowish-white; both it and the bark have a peculiar odour. Leaves on short stalks Flowers unknown. Fruit ovate, smooth, brown somewhat larger than a pea; surmonnted at the base by a four-toothed calyx, and supported on a very short stalk.

Dr. Royle has adopted the above description, as translated by his friend, Dr. Pereira, who has closely followed the account given by Nees von Esenbeck in the folio work *Beschreib Officin* : *Planzen*, where he says that his friend Dr. Ehrenberg collected from off this tree "*sehr schone Myrrhe*," and that the description is taken from the specimens of the plant collected by Ehrenberg at Gison, on the borders of Arabia Felix. Though it is not very probable, from modern information, that any large quantity of Myrrh is produced in Arabia, yet it is possible that some may be produced there, and from the same species of plant as that which yields the large quantities of Myrrh in Africa. Indeed, it is stated in the Appendix to Harris' Abyssinia (ii. 414), probably on the authority of Dr. Roth, that the "*Balsamodendron Myrrha* (*Karbeta* of the natives) grows on the borders of Efat and in the jungle of the Hawash, and in the Adel desert. The resinous gum called *Hofali* is collected for exportation. *B. Opobalsamum* (Besham) grows commonly with the former, and grows even at Cape Aden." Unfortunately there are no specimens of either plant in the Herbarium collected by the embassy and sent to the India House. On examining the specimens in the British Museum of *B. Opobalsamum* or *B. Gileadense*, now united into one species, it appears to Dr. Royle that the specimens vary sufficiently to require careful examination and detailed description of good and complete specimens, before we can distinguish them as varieties, or determine them to belong to separate species; also whether the above *B. Myrrha* itself differs sufficiently to constitute a distinct species. The drawing of Nees, appears to Dr. Royle to resemble some of the Arabian specimens of *B. Opobalsamum* very closely. All are very distinct, both in foliage and inflorescence, from *B. Kataf* (v. 56, 1, 2, 3), of which a specimen collected by Forskal is in the British Museum. The species referred to by Dr. Roth are probably the same as the following.

Mr. Johnston, also, in his Travels through Adel to Abyssinia (i. p. 249), in treating "of the tree that yields this useful drug, Myrrh," says "there are in the country of Adel two varieties, one a low, thorny, ragged-looking tree, with bright green leaves, trifoliate, and an undulating edge, is that which has been described by Ehrenberg." (v. the annexed figure, 56.) "This produces the finest kind of Myrrh in our shops." This may be either the above *B. Myrrha* or one of the forms of *B. Opobalsamum*. "The other is a more leafy tree, if we may use the expression, and its appearance reminded me exceedingly of the common hawthorn of home, having the same largely serrated, dark-green leaves, growing in bunches of four or five, springing by several leaf-stalks from a common centre. The flowers are small, of a light-green colour, hanging in pairs beneath the leaves, and in size and shape resemble very much the flowers of our gooseberry-tree. It belongs to the Octandria Monogynia, the eight stamens being alternately long and short, the former corresponding to the four partial clefts in the edge of the one-leafed calyx. The fruit is a kind of berry, that when ripe easily throws off the dry shell in two pieces, and the two seeds it contains escape. The outer bark is thin, transparent, and easily detached; the inner, thick, woody. When wounded, a yellow turbid fluid (the gum-myrrh) immediately makes its appearance. Naturally, the gum exudes from cracks in the bark of the trunk near the root, and flows freely upon the stones immediately underneath. Artificially, it is obtained by bruises made with stones." This plant, judging from the specimens deposited by Mr. Johnston in the British Museum, corresponds exactly with one, also in the same collection, obtained by Mr. Salt in Abyssinia, *Balsamodendron Kua* of Mr. Brown's MSS. and of which Mr. Salt says, he obtained from it a gum much resembling the Myrrh.

Balsamodendron Africum, Arnott.—Heudelotia africana. Guill. et Per. This species, first found on the west of Africa, occurs also in the Abyssinian collection, having been found in the flat country of the Adel. Mr. Johnston immediately recognized it as one of the trees yielding gum-resin. The leaflets are like those of *B. Kua*, Br. It yields African Bdellium, or that imported into France from Guinea and the Senegal, according to M. Porrottet. M. Adanson, likewise, in his Travels in the Senegal, mentions it by the name of Niotout as producing Bdellium. It may also yield the Bdellium which is exported from the west coast of Africa. Dr. Malcolmson wrote to Dr. Royle that "Bdellium (of which he sends a specimen) is produced in Africa by a tree similar to the Myrtle. None is obtained in Arabia. It is very similar to Myrrh, and sometimes sold for it."

One kind of Bdellium is produced in India, which Dr. Royle was informed was yielded by a tree called *googul* by the natives (v. Himal. Bot. 177), and which is the *Amyris Commiphora* of Roxb. referred by Messrs. Wight and Arnott to Balsamodendron. Dr. Walker, in his account of the drugs produced near Aurungabad, states "a gum-resin, called by the natives *googool*, is produced by a tree (Dr. W. calls it Amyris Bdellium? Roxb.) which grows in the neighbourhood of

Umber, a town twenty miles to the westward of Aurungabad. Roxburgh imagined that Googool was identical with Myrrh." But the whole of the species of this genus require to be carefully examined from good and authentic specimens accompanied by their respective products, before the several doubts can be resolved. *Prop.* Myrrh is imported from Bombay. It is generally in pieces of irregular form and size, formed apparently by agglutinated tears, dry, and covered with a fine dust, commonly of a reddish-brown colour; brittle, fracture irregular, conchoidal, shining, with the surface apparently dotted with volatile oil, often varied, with opaque, whitish, semicircular marks; the smaller pieces angular shining, semi-transparent; taste bitter and aromatic, the smell peculiar and balsamic. Other kinds are also met with, probably derived from the same source, as it sometimes reaches this country with the different qualities intermixed (*Myrrh* in sorts) or when the finer pieces are picked out (Turkey or picked Myrrh). But when the process is adopted abroad, the inferior qualities may come separately or remain intermixed with other gums or resins, especially Bdellium, from the careless manner in which all are collected by the natives. The specimens brought by the Abyssinian embassy have *granular* fragments mixed with roundish tears; and some of a pale, even whitish, colour may be seen on the same piece of bark with ordinary coloured Myrrh. The specimens which have not been exposed to the air, are darker coloured, moister, and of a more powerful and agreeable smell.

Indian Bdellium is sometimes sold for and considered as an inferior kind of Myrrh. It is in roundish pieces of a dull dark-red colour, more moist than Myrrh, and not brittle like it, softening even with the heat of the hand; bitter and a little acrid in taste, with a less agreeable odour. It often has portions of the birch-like bark adhering to it. Myrrh, when heated, softens, then burns partially, leaving a black spongy ash. Triturated with water, it forms an emulsion: the Alcoholic tincture is rendered opaque on the addition of water. It is a Gum-resin with volatile Oil, and salts of several acids combined with Potash and Lime. The Gum, about 63 per cent., consists of two kinds, one-half being *Bassorin* or insoluble, and the remainder *Arabin*, or soluble Gum. This being dissolved in water, readily suspends the Resin and Oil. The Resin, about 28 per cent., is also of two kinds, one soft, odorous, and soluble in ether, while the other is hard, without odour, soluble in alkalis. The volatile Oil, about 2·5 per cent., passes over if distilled with water; it is at first without colour, but becomes yellowish, has the odour and taste of Myrrh, is soluble in Alcohol, Ether, and the fixed Oils. Upon it and the Resin the properties of Myrrh chiefly depend. *Action. Uses.* Stomachic, Excitant, Stimulant Expectorant, Emmenagogue, *D.* gr. x to xxx. but usually united with tonics or with purgatives, as Aloes.—*Royle.* The sort met with in India, and brought from the Arabian and African Coasts, is in large opaque pieces, generally covered with a brownish white powder. An interior kind of Myrrh is also imported from the above places, and termed in India Bysabole. It has a great resemblance to Bdellium, for which it is not unfrequently mistaken. Myrrh is largely imported into Bombay, and is chiefly re-exported to England.—*Faulkner.*

(5546) MYROBALANS. This is a name applied to the almond-like kernels of a nut or dried fruit looking like a plum, of which there are several sorts known in the East. They are the produce of various species of *Terminalia*; as *T. Bellerica*, *T. Chebula*, *T. citrina*, and *T. angustifolia*. They vary from the size of olives to that of gall nuts, and have a rough, bitter, and unpleasant taste. Many of the trees of this tribe, which are all natives of the tropical regions of Asia, Africa, and America, are used for tanning, and some for dyeing. They are highly valued by dyers, creating, when mixed with alum a durable dark-brown yellow. Myrobalans fetch in the Bombay market 8*s.* to 26*s.* the Surat candy of 821 lbs. The bark and leaves of *T. Catappa* yield a black pigment, with which Indian ink is made; the seeds are eaten like almonds. A milky juice is said to flow from *T. angustifolia*, which when dried, is fragrant, and, resembling Benzoin, is used as a kind of incense in the Catholic churches in the Mauritius. The fruit of *T. Bellerica*, and of *T. Chebula*, both useful timber-trees, indigenous to the East Indies, are used medicinally as a tonic and astringent. One hundred and seventeen cwts. of Myrobalans were shipped from Ceylon in 1845. The annual imports of Myrobalans into Hull, amount to about 1600 cwts. The quantity which arrived at Liverpool was 185 tons in 1846, and 851 tons in 1850; 27,212 bags in 1851, and 19,946 bags in 1852; they came from Calcutta and Bombay, and are used for dyeing yellow and black. The price in January 1853 was 6*s.* to 12*s.* per cwt. The average annual imports into the United Kingdom may be taken at 1200 tons. Myrobalana is also the English name given by Lindley to the natural order *Combretaceæ*, which yields these fruits. [COMBRETACEÆ; EMBLICA.] (Simmonds, *Commercial Products of the Vegetable Kingdom.*) —*Eng. Cyc.* This fruit of several East Indian trees, is used in India as a substitute for galls. When ripe, the fruit is pear-shaped, deeply wrinkled, and of a brownish yellow colour: it weighs from 70 to 100 grains. The husk contains the whole of the astringent matter, some mucilage, and a brownish yellow colouring substance, which is used in India for dyeing yellow. The husk is easily separated by bruising the nut, which it encloses. The tannin

of myrobalans differs slightly from that of gall. Gallic acid is also present in rather large proportion. The price of myrobalans in June 1852 was quoted at from 6*l.* to 10*l.* per ton. The *Myrobalans* of commerce yielded by *Terminalia chebula*, *belerica* and *citrina* (called also Gallnuts) are oval fruits of a dingy yellow colour, containing much tannin; hence, they are useful to the tanner as well as the dyer. With alum, this dye yields a good durable yellow, and with salts of iron, a black colour, little inferior to that produced by Oak Galls. The Myrobolans although a very common dyeing and tanning material of this country from time immemorial, have not been many years introduced into English commerce, but so useful have they been found, that they have become a very important article of trade, and the consumption is now fully 2000 tons annually (Archer).—*Tomlinson*. On this subject, the Canara Local Committee observes as follows:—"During the last season a sudden demand "arose for the Gallnut, and large profits were "made by the persons who collected it from the "jungles. The exports for five years have been "as follows:"—

Fuslies.	Quantity.		Value.		
	Candies.	Mds.	Rs.	As.	P.
Fusly 1256.....	207	3	918	,,	,,
1260.....	380	16	1877	,,	,,
1261.....	537	19	2860	,,	,,
1262.....	520	17	2614	,,	,,
1263.....	2154	4	3029	,,	,,

All the three Myrobolans are to be met with in many parts of lower India. In Bengal they grow in abundance. In Java we are told by Buntins, (1) that the Dutch were in the habit of employing the Embic and Beleric sorts daily in their hospitals, in dysenteric, and bilious affections.—*M. E. J. R. Ainslie.*

Har, Harra, from Terminalia chebula, and other species, three in number, comprise all the discarded myrobalans of our old pharmacopœas. The myrobalans as brought into Cashmere from Delhee and Harowtee, Hindusthan and the Dukhan, are of four kinds namely:

Gural harra.—Astringent and purgative: used in mesalibs: given in medicine to children: four seers for one rupee.

Juwal harra.—Used in the same way; eight seers for one rupee.

Chaipel harra, used only in dyeing, ten seers for one rupee. The whole are much used in dyeing. According to the size of the myrobalan its value augments, so that a very large one may be worth one hundred rupees or more, the natives believing that the very large ones have the virtue of causing purging by being merely retained in the hands—*Gen. Med. Top. p.* 136. The Har or Harra, is, says Dr. Irvine, one among the articles of the native materia medica than which no one is more vaunted. It is considered to possess wonderful general deobstruent and purgative qualities &c. &c., while those who thus belaud it, are apparently not aware that this is the chebulic myrobalan (Terminalia chebula) of English pharmacopœias of the sixteenth century and long since deservedly neglected.—*Gen. Med. Top. p.* 153.

(5547) MYROBALAN, BELLERIC. TERMINALIA BELLERICA. Roxb.

Beleyluj, ARAB.	Belelah. Belegleh, PERS.
Booloo, CYNG'	Behira, Veebitaka, SANS.
Bella, DUK.	Tanikai, TAM,
Behevra, Beeda, HIND. GUZ.	

The fruit of the Bellerie Myrobalan, in its dried state, is little larger than a gall-nut, but not so regular in shape, of a dirty brown colour, and astringent taste. It is supposed to be similar in its properties to the Chebulic Myrobalan, but in a much weaker degree. It is much used in India as the basis of several colours, and also in medicine. Small quantities have of late years been exported from Bombay to England.—*Faulkner.* This article is sometimes used by the natives in its dried state in cases requiring slight astringents. The large tree which produces it, is common in Mysore, where it is called Tari; and hence the botanical name (Myrobolanus Taria) given to it by Dr. Buchanan. It would appear to be the Tani of Rheede.—*Ainslie's Mat. Med. p.* 28. Bellerie Myrobalan fruit is esteemed medicinal by the Burmese, and is dried and sold among the drugs. The tree is indigenous, but not very abundant.—*Mason.*

(5548) MYROBALAN, BLACK, OR INDIAN.

Heleelaj Aswad, ARAB.	Helcelah Seeah, PERS.
Zengi har, BENG.	Kurkadaga, SANS.
Hemuz, Hemuj, GUZ. H.	Sinhgi, TAM.

Is the unripe dried fruit of the *Terminalia chebula*. It is about the size of a pistachio nut and of a deep black colour, oblong, pointed at both ends, slender, and has scarcely the rudiment of the nut. It is used by the natives of India as a brisk purge; and also as a dye. In Bengal and in most parts of the Western Presidency, they are grown in abundance. They are largely exported from Bombay to the Arabian and Persian Gulfs.—*Faulkner.*

(5549) MYROBALAN, CHEBULIC. COUNTRY GALLS. Terminalia Chebula, Willd.

Heleeluj Kabulee, ARAB.	Humbether GUZ. HIND.
Araloo, CYNG.	Helcelah—kilan, PERS.
Huldah, DUK.	Haritaka, SANS.
Hurda, HAR. HAR,	Kadukai, TAM.
	Carakaia, TEL.

In its dried state, it is about the size of a large Spanish olive, of an oblong ovate shape, yellow brown colour, and is marked with edges and furrows alternately. The tree (*Terminalia chebula*),

which yields this fruit, is common in the Mysore country, Bengal, and in some parts of the Western Presidency. This fruit is infinitely more astringent than the preceding, and is on that account, much more extensively used by the natives in their arts and manufactures. They are exported from Bombay to London and Liverpool in large quantities.—*Faulkner.* This species is infinitely more astringent than the preceding, and it would appear by some experiments made by Dr. Roxburgh, that it is even more so than the Aleppo Galls. Kadukai well rubbed in conjunction with Galls and Cuttacamboo (of each equal parts) is considered by the Vyteans as an excellent external application in the apthous affections of children, and adults, the last of which is a most dangerous disease amongst the Native Indians. The tree which produces the Kadukai is common in Mysore, where it is called Arulay, and hence the Botanical name (Myrobolanus) given to it by Dr. Buchanan.—*Ainslie's Mat. Med.*

(5550) MYROBALAN, CITRINE. MYROBOLANUS CITRINA.

Alay-gara, TAM.	Liba, SANS.
Harra, Harva, GUZ. H.	

The Citrine Myrobalan (*Terminalia citrina*), is ranked among the fruits; it is about the size of a French plum, and is often made into pickle, and when green, is used as a gentle purgative. It is frequently met with in most parts of Lower India. This fruit grows in Canara, it is not much prized and is generally made into pickle.—*Ainslie.*

(5551) MYROBALAN EMBLIC. EMBLICA (OR PHYLLANTHUS) OFFICINALIS. Phyllanthus Emblica, *Linn.*

Amla Anola, BENG.	Aoonla, Amlej, DUK.
Cayboung Ngot, Hac-min-sau, COCH-CHIN.	Amleh, PERS.
	Amalaka, Amrita, SANS.
Amla, Anvelcutty, Aoonla Aunwera, GUZ. HIND.	Nelliekai, TAM.
	Woosheerikaia, TEL.
Awusadanelli, CYNG.	

The Emblic Myrobalan in its dried state, is about the size of a small marble, of a dirty, dark-brown colour, and irregular surface, possessing a considerable degree of astringency. It is to be met with in most parts of lower India. In Bengal they are grown in abundance. It is reckoned among the Indian fruits, and in its green state, is frequently made into preserve and pickle; it is also used in medicine.—*Faulkner.* In its dried state it is with other articles of similar qualities, made into a cooling and opening Ptisan. The tree which produces this article is the Nilicamarum of the Hort. Mal. and the Boa Malacca of the Malays.—*Ains. Mat. Med. p.* 29.

(5552) MYROSPERMUM, a genus of plants belonging to the natural order *Amyridaceæ*. It has a 5-toothed campanulate calyx; 5 petals, the upper one largest; stamens 10, distinct; ovary stipitate, oblong, membranous, with 2-6-ovules; legume with a winged stalk, terminating in an oblique indehiscent 1-celled 1-2-seeded samara. The species are trees with dotted leaves.—*Eng. Cyc.*

(5553) MYROSPERMUM. PERUIFERUM. (Myroxylon Peruiferum Linnæus), Balsam of Peru Tree. The stem of this plant yields the Balsam of Peru. It has a thick smooth straight trunk with a gray coarse bark, which is filled with resin. By distillation with water it yields a volatile oil. By exposure to the air it hardens, and is then termed Opobalsamum Siccum, which must not be confounded with the true Opobalsamum. Balsam of Tolu is also sometimes called Opobalsamum.—*Eng. Cyc.*

(5554) MYRTACEÆ, *Myrtle Blooms*, Polypetalous Exogens, forming a very extensive and important natural order of Plants, exclusively inhabiting warm countries, and in all cases either shrubs or trees, an herbaceous form of the order being unknown. The most northern station of the species is the south of Europe, where the common Myrtle grows apparently wild. If this plant is taken as the type of the order, it might be said to consist of aromatic plants with opposite leaves, dotted with transparent oil-cysts, bearing icosandrous monogynous polypetalous flowers, succeeded by an inferior succulent fruit; but this is the character rather of a section of the order than of *Myrtaceæ* considered as a whole. In this division are however included nearly all the species employed for the use of man. Among the table-fruits of the tropics are—the Guava, yielded by different species of *Psidium*; the Rose-Apple and Jamrosade, produced by *Eugenia Malaccensis* and *E. Jambos*: of spices, Cloves are the flower-buds of *Caryophyllus aromaticus*; and Allspice is the dried berries of *Eugenia Pimenta*; all which are obtained from the plants belonging to the same section as the Common Myrtle; the aromatic fruits of that plant were indeed used as a spice before Cloves and Allspice became common.

The deviations that take place from the typical structure of the order consist partly in the fruit being dry and capsular instead of fleshy and indehiscent, and partly in the organisation of the interior of the fruit being educed to a state of great simplicity; besides which the leaves are often alternate instead of opposite. Some of the species have no corolla, and there is in many cases a very singular tendency to consolidate the floral organs of all kinds.

The species with capsular fruit are principally found in Australia, where, in the form of *Eucalyptus* and *Leptospermum*, they constitute one of the most striking features of the vegetation. These plants abound in a powerful astringent secretion, chiefly found in their bark, on which account they are found valuable for

the tanner's purposes; while the aromatic principles is also abundantly secreted in other cases, as, for example, in *Melaleuca Cajeput*, from which the green stimulating oil of the Cajeput is procured. It is more particularly among these species that anomalous conditions of the floral organ occur. In *Eucalyptus* there is no corolla, and the segments of the calyx are so completely united to each other as to form a fleshy cap, thrown off by the flowers when the time arrives for extricating the stamens. In *Melaleuca*, *Calothamnus*, and several others, the stamens are united to each other by their filaments, so as to form showy, petal-like, fringed expansions; and in *Eudesmia* the petals themselves are united into a cap, thrown off upon the expansion of the flower.

The most singular form of *Myrtaceæ* is that which derives its name from an Australian plant, called *Chamælaucium*, in which the interior of the ovary contains but one cell, with from two to five ovules rising up obliquely from its base. These plants are all small heath-like shrubs, having in the majority of cases the edge of the petals prolonged into long and delicate fringes. Such plants are extremely abundant on the west coast of Australia, where they form one of the most striking characters of the Flora. *Punica Granatum*, the Pomegranate-Tree, is a most anomalous form of *Myrtaceæ*, remarkable for an almost total absence of transparent dotting, and consequently of aromatic qualities; and having a fruit consisting of two whorls of carpeds compacted together into an inferior ovary, the interior of which becomes altered and distended so much after the flower has fallen off, that the fruit is nothing but a collection of cavities filled with seeds, and having no apparent relation to each other.

The genus *Caryophyllus* has the following characters:—Tube of the calyx cylindrical; limb 4-parted; petals 4, adhering by their ends in a sort of calypra; stamens distinct, arranged in 4 parcels in a quadrangular fleshy hollow near the teeth of the calyx; ovary 2-celled; ovules about 20 in each cell: berry 1-2-celled, 1-2-seeded; seeds cylindrical or half-ovate; cotyledons thick, fleshy convex externally, sinuous in various ways internally.

C. aromaticus, the Clove-Tree, is a native of the Moluccа Islands. It is a moderately-sized tree, with leaves opposite and decussate, persistent, somewhat coriaceous and shining, minutely punctuated, about 4 inches long, ovate-lanceolate, more or less acute, quite entire, pale beneath, tapering gradually at the base into a slender footstalk which is almost 3 inches long. The cloves of the shops are the dried compressed flower-buds of this tree.—*Eng. Cyc.*

(5555) MYRTUS (*Μύρτος*), a genus of Plants, the type of the natural order *Myrtaceæ*. It has the calyx-tube somewhat globose, with the limb 5- or very rarely 4-partite; the petals 5, or very rarely 4; the stamens distinct; the berry 2- or 3-celled, somewhat globose, crowned with the segments of the calyx; several seeds in each cell, or very rarely solitary; uniform, with a bony testa; the embryo curved; cotyledons semi-cylindrical, very short, the radicle twice the length of the cotyledons. The species are shrubs with opposite quite entire pellucid dotted leaves; peduncles axillary, 1- or rarely 3-flowered.—*Eng. Cyc.*

(5556) MYRTUS COMMUNIS, Common Myrtle, has solitary 1-flowered pedicels about the length of the leaves, bearing 2 linear bracteoles under the flowers; the calyx 5-cleft; the leaves ovate, lanceolate, or acute. This beautiful plant is a native of the south of Europe; it is found wild in France, about Marseilles, and extends from that city along the sea-coast to Genoa, and throughout Italy. In these districts it forms thickets which sometimes grow within reach of the spray of the sea. This plant has been in all ages a great favourite in Europe. It was called by the Greeks *Μύρτος*. *Μυρσίνη* is the name under which Hippocrates refers to this plant. ('Morb. Mul.,' i. 599.) Theophrastus also uses this word, and *Μυρτίνη* and *Μυρτίς*, in speaking of the Myrtle. The Romans knew this plant by the name of Myrtus. (Pliny, 12-13.) This name has been adopted in most European languages. It is Mirto in Italian and Spanish; Myrte in German; Myrter in Danish; Myrten in Swedish; Mirte in French; Mirta in Portuguese. The leaves of the Myrtle, like the whole order, contain a volatile oil which possesses medicinal properties, and they were used as stimulants by the ancients. The buds and berries of this plant also contain volatile oil, and were used by the Romans as a spice, and are at this day in Tuscany employed as a substitute for pepper. The Tuscans also prepare a kind of wine from the Myrtle called Myrtidanum. The berries are used at the present day in Greece as a remedy in the diarrhœa of little children. The mode of administering them is to soak them in red wine. The flowers of the Myrtle have an agreeable scent, and when distilled they form the perfume sold in France under the name of Eau d'Ange. In addition to the volatile oil the Myrtle contains tannin, so that in medicine its various parts have an astringent action, and have been used for this purpose. In Greece, Italy, and the south of France, the bark is used for tanning. The varieties are the Gold-Striped Broad-Leaved Myrtle, Broad-Leaved Jew's Myrtle, Gold-Striped-Leaved Orange-Myrtle, Silver-Striped Italian Myrtle, Striped Box-Leaved Myrtle, Silver-Striped Rosemary-Leaved Myrtle, Silver-Striped Nutmeg Myrtle, Cockscomb or Bird's-Nest Myrtle, Spotted-Leaved Myrtle. About 40 other species

of Myrtle besides those of the old genus *Myrtus*, now referred to the genera *Myrica*, *Eugenia*, &c., have been described. None of them yield products used in arts or medicine, and only a few of them have been cultivated.—*Eng. Cyc.*

(5557) MYRTUS NUMMULARIA is a creeping species found at the Straits of Magalhæns; and *M. myrsinoides*, a native of the colder parts of Peru, would probably be found to be half-hardy in England (Loudon, *Arboretum Britannicum*; Fraas, *Synopsis Floræ Classicæ*; Burnett, *Outlines of Botany*; Lindley, *Flora Medica*. —*Eng. Cyc.*

(5558) MYRTUS SPECTABILIS, M. TOMENTOSA.

(5559) MYRTUS TOMENTOSA, is a native of Cochin China. It is a handsome shrub, and has been found to grow well against walls in the south of England.—*Eng. Cyc.*

(5560) MYTILIDÆ, a family of Lamellibranchiate *Mollusca*. It includes the species referred by Linnæus to the genus *Mytilus*. Mr. G. B. Sowerby ('Genera'), after remarking that the Linnæan genus *Mytilus*, on account of its principal character being its want of hinge teeth, consists of several forms that are widely distinct from each other, and which have well served as the types of several Lamarckian genera, such as *Avicula*, *Modiola*, *Anodon*, and others, in connection with the present genus, which deservedly retains the name of *Mytilus*, both on account of its form and the priority of its claim, proceeds to observe that the other genera which have been united with it but from which it appears necessary to distinguish it because of a certain degree of general resemblance, are *Modiola* and *Lithodamus*: from *Anodon* and *Avicula*, together with Lamarck's *Meleagrina*, it is, he adds, obviously distinct: whilst one character—namely, the pointed terminal umbones—serves to distinguish it from *Modiola* and *Lithodomus*.—*Eng. Cyc.*

(5561) MYTILUS. This genus is abundant on most rocky coasts, where the species are to be found moored by their coarse filamentous byssus, generally to such rocks or other submarine bodies as are exposed at some periods of the tide where tides exist, and covered by the sea at high water. Mr. G. B. Sowerby does not think that, after being once attached, they habitually disengage themselves, though it appears to him probable that, when disengaged by the force of the sea, they may live for some time without being in any manner, affixed. The species are numerous, and most of them are used as food; but they should be eaten with caution, for serious illness and even death have insued from a meal made on some of them. The byssus, or beard, as it is popularly called, should be carefully cleared away, and they should be particularly avoided when cholera is about, or even when diarrhœa is prevalent.—*Eng. Cyc.*

(5562) MYTILUS. EDULIS, the Common Salt-Water Muscle. This species is too well known to require description: the shell, is strong. When freed from the epidermis and polished, the under surface of the external parts of the shell is exposed, and is of a deep blue. In this state it is often offered for sale at watering places. The inside of the valves is white with a dark rim. The Common Edible Muscle is found in extensive beds below low-water mark, and also at a greater depth. Rocks and stones between high-water marks are also covered with them.

N.

(5563) NAA. A very hard, fine, close-grained, and very ponderous Ceylon wood.

(5564) NADULEE. A stone engraved with a verse of the koran, and suspended as a charm round the necks of children.—*Herklots.*

(5565) NAGEESA HIND. There is much dispute amongst oriental scholars about the wood Nageesa; the Bombay philologists refer it to a species of *Garcinia*, whilst the pundits on the Calcutta side of India consider it to be *Mesua ferrea*. Throughout his travels in India, Dr. Hooker was struck with the undue reliance placed on native names of plants, and information of kinds: and the pertinacity with which each guist adhered to his own crotchet as to the application of terms to natural objects, and their pronunciation. It is a very prevalent, erroneous impression, that savage and half-civilised people have an accurate knowledge of objects of natural history, and a uniform nomenclature for them. —*Hooker Him. Jour. Vol.* II. *p.* 328.

(5566) NAGEIA PATRANJEVA: POOTRA JEEVI, TELING Pongalam: Rheed Pootrungeiva Pitanjia. A native of various mountainous countries of Coramandel and Hindoostan, where it grows to be a large timber tree with an erect straight trunk and a large spreading shady head composed of innumerable expanding branches, with bifarious branchlets. Flowering time March and April and the fruit ripening in January.

The wood is white, close grained, and very hard. —*Rhode M.S.S.*

(5567) NAGKESUR, Mesua ferrea. The root of the tree is used: considered astringent and refrigerant: one tola is taken internally: is applied externally in cynanche.—*Ainsl. Mat. Med. Top. p.* 147.

(5568) NAIGRE SEED, is not known at Madras, it is an article of export from Malabar: it is probably the name of the seed of Pongamia glabra.

(5569) NAIA, Laurenti's name for a genus of highly venomous Serpents, to which the species of *Uræus* and *Aspis* of Wagler belong. This form appears to be confined to the Old World. The Asiatic species *Coluber Naja* of Linnæus; *C. cæcus* of Gmelin (?); *Vipera Naja* of Daudin; *Naja tripudians* of Merrem; *N. lutescens* of Laurenti; Cobra de Capello (adder with a hood) of the Asiatic Portuguese; Serpent a Lunettes of the French; Nag and Chinta Nagoo of the natives; and Spectacles-Snake of the English, may be considered as the type of the genus. It has the following characters:—Head with nine plates behind, broad; neck very expansile, covering the head like a hood: tail round. (Gray.) The expansion of the neck and upper part of the body is effected by the anterior ribs, which the animal has the power of raising and bringing forward so as to dilate that portion into a disc more or less large. When this disc is thus dilated in the *Naia tripudians*, it presents on the back part of it no bad representation of a pair of spectacles, or rather barnacles, reversed, for there is no trace of the lateral pieces by which spectacles are attached to the head of the wearer. The animal is brown above, and bluish-white beneath. The following cuts will convey some idea of the form of this snake, with the hood or disc expanded. Colonel Briggs informs us that this active and deadly serpent is sometimes worshipped in temples in India, where it is pampered with milk and sugar by the priests, and he notices it as a surprising instance of the effect of kind treatment in subduing the most irritable spirits. "The Hindus," says the Colonel, in continuation, "have a notion that the sagacity and the long-cherished malice of this worm are equal to that of man. I have seen them come out from their holes in the temples, when a pipe has been played to them, and feed out of the hand as tamely as any domestic animal; and it is when in this state of docility, so opposite to their shy but impetuous nature, the common people believe that the Deity has condescended to adopt that form. It seems probably that this hooded snake was the dragon of the heathen worship; and the shape of its head and its activity when in a state of excitement probably gave rise to the fable of its being winged." It is pretended that the root of the *Ophiorrhiza mungos* is a specific against the bite of this serpent. The priests and jugglers however, who make them dance to astonish or amuse the people, make all sure, there is little doubt, by extracting the poison-fangs. This formidable species, or at least some species of hooded snake, according to the records of travellers, grows to a considerable length. Captain Percival gives the following account of its size and habits, in his 'Account of the Island of Ceylon,' 5to, 18 5:—"The Cobra Capello, or Hooded Snake, is found here from six to fifteen feet long. Its bite is mortal. The natives find the herb pointed out by the ichneumon a remedy, if timely applied. When enraged and preparing to attack, it raises its head and body to the height of three or four feet in a spiral manner, while at the same time the remaining part of the body is coiled up to accelerate and give force to the spring. At this instant it distends from its head a membrane in the form of a hood, from which it receives its name. This membrane lies along the forehead and the sides of the neck, and is almost imperceptible till the animal gets into a state of irritation and is about to attack his foe. When the hood is erected it completely alters the appearance of the head, and discloses a curious streak in the shape of a pair of spectacles, and sometimes of a horse shoe. The extension of this membrane seems intended by Providence to give warning to all those within this animal's reach that he is preparing to attack them. Without this signal he would be very dangerous indeed, as his motions afterwards are too rapid to be avoided. I have more than once been an eye-witness to instances where the fatal bite of this snake was escaped from merely by the object of his vengeance timely observing his preparations. One remarkable characteristic of these dangerous serpents is their fondness for music. Even when newly caught they seem to listen with pleasure to the notes, and even to writhe themselves into attitudes. The Indian jugglers improve greatly on this instinct, and, after taming them by degrees, instruct them even to keep time to their flageolet." The largest Cobra de Capello seen by Dr. Davy in Ceylon was nearly six feet long; and he adds that the general length is between two and four feet. The colour varied: those of a light colour were called high-caste snakes by the natives, and those of a dark colour low-caste. "The natives," says Dr. Davy, "in general rather venerate this snake than dread it. They conceive that it belongs to another world, and that when it appears in this it is merely as a visitor; they imagine that it possesses great power, that it is somewhat akin to the gods, and greatly superior to man. In consequence they superstitiously refrain from killing it, and always avoid it, if possible. Even when they find one in their house, they will not kill it, but, putting it into a bag, throw it into water. They believe that this snake has a good and

generous disposition, and that it will do no harm to man, unless provoked." Dr. Davy gives a pleasing picture of the irritations and soothings with which the snake-charmers excite and allay the temper of this serpent. He records several instances of the operation of the poison, the first arising from a serpent found in a bag floating down the Kalang-ganga. It was about five feet long, and about six inches in circumference in the broadest part. This snake bit a hen, fixing its fangs in the skin covering the lower part of the left pectoral muscle, and keeping its hold about two or three seconds, when Dr. Davy succeeded in shaking it off. The hen, which at first seemed to be little affected, died eight hours after she was bitten. ('An Account of the Interior of Ceylon,' &c., by John Davy, M.D., F.R.S., 4to, London, 1821.) Several Cobras have been kept alive in the Zoological Gardens, Regent's Park. One of these creatures bit one of the keepers on the nose whilst he was playing with it. The man died in a few hours after. The Arabs who accompanied the Hippopotamus had the power of snake-charming; and on several occasions these fearful reptiles were made to go through a variety of performances by a lad not more than 10 or 12 years old. There are several other species of *Naia*. Schlegel, in his essay on the 'Physiognomy of Serpents,' gives the following:—

"*Naia Haje*.—The Aspis of antiquity. This is the snake which is most frequently operated on by the snake-charmers of Egypt, where it is found. [ASP.] It is worthy of observation with reference to the contest in the presence of Pharaoh between Moses and Aaron and the magicians of Egypt (Exodus, vii. 9,12), that it is stated, on good authority, that the modern Egyptian jugglers possess the power of throwing the *N. Haje* into a state of catalepsy, and rendering it stiff and immoveable, in other words, changing it into a rod, by pressing the nap with the fingers.

Nabalus Bungarus.—Is a rare species, inhabiting the islands of Java and Sumatra. It is the *Bungarus* of Daudin.

Nabalus Curta.—A native of Australia. We owe to Dr. Cantor, who has added so much to our knowledge of the natural history of Asiatic serpents, the introduction of a new genus of hooded snakes, *Hamadryas*, which will probably find its proper place in the series as a sub-genus of *Naia*.

Hamadryas (Cantor). Head broad, subovate, deplanate, with a short obtuse rostrum, covered above with 15 scuta; cheeks tumid; eyes large, prominent, pupil round; nostrils widely opened, within the confine of two scuta; gape very ample, subundulated. Poison-fangs anterior, behind which are the maxillary teeth. Neck dilatable. Body thick, smooth, imbricated with smooth scales disposed in oblique rows. Tail short, covered with scuta and scutella, its apex acute.—*Cantor*.

H. ophiophagus (Cantor). Above olive-green, girt with black sagittal striæ; abdomen glaucous, marbled with black. The Hindustanee name is Sunkr Choar. It is a native of Bengal. Dr. Cantor thus describes the habits, the effect of the poison, and the history of this serpent:—"The *Hamadryas*, like the *Bungarus*, *Hydrus*, and *Hydrophis*, has a few maxillary teeth behind the poison-fangs, and thus, like the latter, connects the venomous serpents with isolated poison-fangs to the harmless, which possess a complete row of maxillary teeth. "Of the terrestrial venomous serpents, the *Bungarus* is chiefly characterised by a distribution of the teeth similar to that of the *Hamadryas*, which also partaking of the chief characteristic of the genus *Naja*, namely, that of forming a hood or disc, constitutes an immediate link between the genera *Bungarus* and *Naja*. "In consequence of the strong resemblance in the general appearance between the *Naja* and the *Hamadryas*, when first my attention became attracted to the latter, I thought I could refer this serpent to that genus; and it was not until I was able to examine a specimen whose poison-fangs were untouched (those of the first specimens I saw having been drawn by the natives, who are greatly afraid of this serpent), that I discovered the maxillary teeth behind the poison fangs.

"*H. ophiophagus* differs from the Naja *tripudians*:—1, By its maxillary teeth; 2, by the strongly-developed spines on the os occipitale inferius; 3, by the covering on the head; 4, by the integuments covering the abdominal surface of the tail; 5, by its colour; 6, by its size. According to the natives, the *Hamadryas* feeds chiefly upon other serpents: in one I dissected I found remains of a good-sized monitor, which fact may account for its arboreal habits, as I have in Bengal, along the banks of the rivers, observed numbers of those large lizards among the branches of trees watching for birds. "The power of abstaining from food, generally speaking, so characteristic of the Serpents, is but in a comparatively small degree possessed by this species; the most protracted starvation amounts to a period of about one month; while the *Vipera elegans*, the *Naia tripudians*, and the *Bungarus annularis*, have, without inconvenience, been confined in cages without any food for more than ten months. Two specimens of the *Hamadryas*, in my possession, were regularly fed by giving them a serpent, no matter whether venomous or not, every fortnight. As soon as this food is brought near the serpent begins to hiss loudly, and, expanding the hood, rises two or three feet; and retaining this attitude, as if to take a sure aim, watching the movements of the prey, darts upon it in the same manner as the *Naia tripudians* does. When

the victim is killed by poison, and by degrees swallowed, the act is followed by a lethargic state, lasting for about twelve hours. Such of the other India venomous serpents, the habits of which I have had opportunity to study from life, show themselves much inclined to avoid other serpents, however ready they are to attack men or animals when provoked or driven by hunger; and I am not aware of any other of those serpents being recorded as preying upon its own kind. A short time ago however, during my sojourn at the Cape of Good Hope, I received from high authority the following fact, which throws a light upon the habits of the *Naja* of Southern Africa, one of which, when being captured, threw up the body of a *Vipera arietans* (*V. brachyurus*, Cuvier), which bore marks of having been submitted to the process of digestion. "The *Hamadryas*, like the greater number of Indian serpents, evinces a great partiality to water. With the exception of the Tree-Serpents (*Leptophina*, Bell), they all not only drink, but also moisten the tongue, which, as this organ is not situated immediately in the cavity of the mouth, become in the serpents two different acts. Specimens of this serpent in my possession changed the skin every third or fourth month, a process which takes place in all the Indian serpents several times during the year. The *Hamadryas* is very fierce, and is always ready not only to attack but to pursue when opposed; while the *Cophias*, the *Vipera*, the *Naja*, and the *Bungarus* merely defend themselves, which done, they always retreat, provided no further provocation is offered. The natives of India assert that individuals are found upwards of 12 feet in length —a statement probably not exaggerated, as I have myself seen specimens from 8 to 10 feet in length, and from 6 to 8 inches in circumference, I have often heard it asserted that 'Cobras' (which name is naturally enough given to every hooded serpent) have been met of an enormous size, but I strongly doubt their belonging to the genus Naia, among a considerable number which have come under my observation, I never saw any exceeding 5 to 6 feet in length, while the common size is about 4 feet. Some time before I discovered the *Hamadryas*, I was favoured by J. W. Grant Esq., of the Hon. Company's Civil Service, with an interesting description of a gigantic hooded serpent he had observed in the upper provinces, and which, he remarked, was not a *Naja*. By inspection this gentleman denied the *Hamadryas* to be indentical with the above-mentioned. "The natives describe another hooded serpent, which is said to attain a much larger size than the *Hamadryas*, and which, to conclude from the vernacular name, Mony Choar,' is perhaps another nearly allied species.

"The fresh poison of the *Hamadryas* is a pellucid tasteless fluid, in consistence like a thin solution of gum arabic in water; it reddens slightly litmus paper, which is also the case with the fresh poison of the *Cophias viridis*, *Vipera elegans*, *Naja tripudians*, *Bungarus annularis* and *Bungarus caeruleus*. When kept for some time it acts much stronger upon litmus; but after being kept it loses considerably, if not entirely, its delcterious effects.

"From a series, of experiments upon living animals, the effects of this poison come nearest to those produced by that of the *Naja tripudians*, although it appears to act less quickly. The shortest period within which this poison proved fatal to a fowl was fourteen minutes, whilst a dog expired in two hours eighteen minutes after being bitten. It should however be observed that the experiments were made during the cold season of the year."—*Eng. Cyc.*

Nabalus Elaps.—Is a very large snake, but its country is unknown.

(5570) NAILS.

Spykers, Dut.	Chiodi, Chiovi, Aguti,
Clous, Fr.	It.
Nagel, Spiker, Ger.	Pregos, Port.
Keela, Meikh, Guz. Hind.	Gwosdi, Rus.
	Clavos, Sp.

Are small spikes of iron, copper, brass, &c. which, on being driven into wood, serve to bind or keep together several parts or pieces. The principal seats in England of this useful branch of the iron manufacture are at Birmingham, Bilstone, and Wolverhampton. Iron nails are largely made in Bombay, and are chiefly used in the construction of houses, sailing vessels, &c.—*Faulkner.*

(5571) NAK-CHIKARA. The leaves of a small plant found about Ajmeer, also imported from Delhi: are very hot, and a good sternutatory: three massee are given in pills, as a dose in colic, which is said to be thus speedily relieved.—*Gen. Med. Top. p.* 147.

(5572) NALAPANA KULINGOO, Cæsalpigo orchioides.

(5573) NIMA QUASSIOIDES, (Hamilton.) *Syn.* Simaruba Quassioides, Don. This is a native of the Himalayas. It was discovered in Nipal by Dr. Hamilton, and is stated by Dr. Royle to exist in Turanda, on the banks of the Sutledge, in more than 31° of N. latitude. Dr. Royle has also met with it in valleys in Gurhwahl. In general appearance and intense bitterness this tree is too closely allied to the Simarubeæ to permit their separation. The wood of this tree is light coloured and very bitter, and although it has not as yet been subjected to experiment, we are led from analogy to entertain the most confident opinion of its proving a perfect substitute for the West Indian article.—*O'Shaughnessy, page* 569.

(5574) NAMEDE. A rather hard, very fine, close-grained, heavy Ceylon wood.

(5575) NAMELUDDOOOOO.

Neemee ladooo, Tel. | Junglee shumbaloo, Hind.

(5576) NANDINA DOMESTICA. There is a plant, with red berries, which takes the place of our English holly. It is the *Nandina domestica*, and is called by the Chinese the "Teinchok," or sacred Bamboo. Large quantities of its branches are brought in from the country and hawked about the streets. Each of these branches is crowned with a large bunch of red berries, not very unlike those of the common holly, and, when contrasted with the dark, shining leaves, are singularly ornamental. It is used chiefly in the decoration of altars, not only in the temple, but also in private dwellings and in boats, for here every house and boat has its altar—and hence the name of "sacred Bamboo" which it bears.—*Fortune, page* 122.

(5577) NANKEEN, or NANKIN.

Nankings linnen, Dut.	Nankeen, Guz. Hind.
Toile de Nankin, Fr.	Nanquino, It.
Nanking, Ger.	Nanquina, Sp.

A Chinese cotton cloth of either white, blue, or brownish-yellow colour. In point of strength and durability, it is unrivalled by any of the cotton fabrics of Europe. In some of the southern parts of Europe, the warmer parts of America, and the British settlements in Africa, Nankeen is worn by both sexes all the year round, and constitutes the principal article of attire. In England and India it is now almost disused. —*Faulkner*. This kind of cotton cloth is so named from Nanking, where the reddish threads were originally made. They are divided into company's of which there are three qualities, and narrow nankeens; the former are the finest and most esteemed. Nankeens are also manufactured in Canton and other parts of the empire, but the fabric is of an inferior quality. Those made in Canton still maintain their superiority in color and texture over the imitations of other countries. The price varies from $ 45 to $ 90 per hundred pieces. This cloth is extensively worn by the Chinese themselves, who usually dye it with indigo. The exportation is now trifling, and almost wholly to England, although small quantities find their way elsewhere. The duty, which was formerly a discriminating one, has been equalized under the new tariff, and includes nankeens and all other kind of native cotton cloths. —*Morrison*. The durable cotton cloth made in the central provinces, called Nan-keen by foreigners, is the chief produce of Chinese looms from Cotton, the aerial muslins so highly admired by the Hindus not being woven. The nankeen is generally exported without dyeing, but the people usually color it blue before making it into garments. The import of raw and manufactured cotton constitutes a large item in the foreign trade, but forms a small part of the native consumption. In preparing the cotton for spinning, it is cleaned and freed from knots by placing the string of a bow under the heap, and striking it with a beater; the recoil separates it into flocks without injuring the staple. *Williams' Middle Kingdom, Vol.* II, *page* 124. *Nankeens* were formerly sent abroad in considerable quantities, but instead of exporting their own fabrics, the Chinese now purchase cottons from their former customers to a large amount. There are few fabrics more durable than the nankeen, and it forms the principal material for cheap garments among the people and is more or less exported every year to England, Sydney and South America.—*Williams*.

(5578) NAPHTHA, Rock Oil.

Neft, Arab.	Kesoso no abra, Jav.
Bitume de Judee, Fr.	Minuia tauna, Mal.
Nuckteil Mittie-ke-teil, Guz. & Hind.	Bhumi, tailuni, Sans.
	Mun tylum, Tam.
	Boomie tylum, Tel.

An inflammable mineral substance, which is both a natural and artificial product. It is a fine, thin, volatile, colourless fluid which issues out of white, yellow, or black clays in Persia, Media, and other places; a similar liquid is obtained by the distillation of petroleum, caoutchouc, and pit coal in gasworks: the latter kinds have a penetrating and unpleasant odour. Naphtha dissolves the greater number of the essential oils, and the resins; and is extensively used for dissolving caoutchouc to render cloth water proof; with certain vegetable oils, it forms a good varnish, and for this purpose is sometimes substituted for turpentine. In Genoa it is used in the street lamps.—*Faulkner*. Naphtha is a compound of Carbon and Hydrogen, frequently found in the neighbourhood of coal-deposits, and in other parts of the earth. It contains 82.2 of carbon and 14.8 of hydrogen. It is a limpid or yellowish fluid, lighter than water, and hence called Mineral Oil. Its specific gravity is 0.7 to 0.84. It hardens and changes to the substance called Petroleum on exposure to air. It may be obtained from Petroleum by heat, which causes it to pass off in vapour. Naphtha issues in large quantities from the earth in Persia and the Birman Empire. At Rangoon, on one of the branches of the river Irawaddy, there are upwards of 500 naphtha and petroleum wells, which afford annually 12,000 hogsheads. In the peninsula of Abcheron, on the western shore of the Caspian, naphtha rises through a marly soil in vapour, and is collected by sinking pits several yards in depth, into which the naphtha flows. There is an abundant spring near Amiano, in the Duchy of Parma. Mr. Dana says that in the United States it was formerly collected for sale by the Senecas and other Indians; the petroleum is therefore commonly called Genesee

belief, that the species is a perfect representative of the valerian of the English Pharmacopœia.—*O'Shaughnessy*, pages 403, 404. *N. Latamani* is a dwarf herbaceous plant with a long hairy taproot. The stems are perennial, very short, and simply divided into a number of shaggy scaly crowns, from which the leaves are produced; the branches erect, downy, and a few inches high; leaves obovate, lanceolate, 5 ribbed downy, those at the base acute, the upper ones obtuse; the flowers are of a pale pink colour, clustered in the axils of the upper leaves, which form a kind of involucre for them. It is a native of Nepaul, on the Himalaya Mountains, and in Delhi, Bengal, and the Dekan. This species is the true Spikenard of the ancients, and is esteemed not only as a perfume but as a stimulant medicine. Oriental writers give it as a remedy for a multitude of diseases, and it seems to be really valuable in cases of epilepsy and hysteria.—*Eng. Cyc.*

(5585) NARDUS, a genus of Grasses belonging to the tribe *Rothellieæ*. It has the spikelets in two rows on one side of the rachis of one flower; glumes absent; outer pale keeled, tapering into a subulate point; stigmas elongate, filiform, protruded at the apex of the flower.—*Eng. Cyc.*

(5586) NAR-PUTTE, the Tamil name of a Ceylon tree which is used for canoes, planks of vessels, &c. It grows to about thirty feet in height, and twenty inches in diameter. It is not durable, and is of little use.—*Edye Ceylon.*

(5587) NARWALI OR NARVALI FIBRE, CORDIA ANGUSTIFOLIA, is found common near Severndroog where ropes are made of the fibres.—*M. E.*

(5588) NARUVEALY, the Tamil name of a Ceylon tree which grows to about twenty inches in diameter, and fifteen feet in height, not of much use. It produces a small red fruit which is of a very glutinous nature, and much esteemed by the natives of Malabar. From the bark of this tree a kind of cordage is made, which is used for the purposes required in the hills, and in the conveyance of timber, &c.—*Edye Ceylon.*

(5589) NARVELL, a Ceylon wood, sometimes called Jambu, in Tamil and Portuguese. It grows to about eighteen inches in diameter, and from ten to fourteen feet in height. It is used for the frames of native vessels and boats, and is not considered as a very durable wood. After it has attained its full growth it produces a berry which the natives use as food.—*Edye, Ceylon.*

(5590) NASTOE EDULIS, used as food in China, is a cryptogamic plant.

(5591) NASTURTIUM, an old word applied to some kind of pungent herb, such as Cress. By the English of the present day it is given to the *Tropæolum majus* [TROPÆOLUM], an American annual with pungent fruit; by botanists, to the Water-Cress and plants allied to it; by the Romans it was applied to a plant resembling Mustard in its qualities. The species now referred to the genus *Nasturtium* were formerly included under *Sisymbrium*. *Nasturtium* was separated by Brown, and is principally distinguished by the position of the cotyledons, a point of primary importance in the whole order of *Brassicaceæ*. In *Sisymbrium* the cotyledons are folded with their back upon the radicle, while in *Nasturtium* their edges are presented to it; in the former the cotyledons are said to be incumbent, in the latter accumbent. This is either grown from cuttings or seeds, and merely requires to be protected from the hot winds to be in flower all the year round; it grows much better in beds than pots. The flower and leaf are eaten mixed with other salads, and the seeds when green are pickled.—*Jaffrey.*

(5592) NASTURTIUM, INDIAN CRESS, *Tropæolum majus* and *minus*, raised from seeds sown at the commencement of the rains, succeeds well if not too much exposed to the sun, of easy cultivation, seldom produces seed on the plains, the introduction of the other species and varieties cannot be recommended. Natives of Peru.—*Jaffrey.*

(5593) NASTURTIUM. WATER, CRESS. Griffith says he found an indigenous species of nasturtium in the Provinces, but he does not appear to have described it.—*Mason.*

(5594) NASTURTIUM. OFFICINALE: SISYMBRIUM NASTURTIUM, the Common Water-Cress. In addition to the characters of the genus, this plant is known principally by the form of its leaves. The upper leaves do not separate into distinct leaflets, being pinnatifid with narrow segments. The petiole of the leaf does not in any manner embrace the stem. The flowers are white, and the pods, when ripe, are about an inch long. It is a native of rivulets throughout the world, and is very plentiful in Great Britain. It has a warm agreeable flavour, and has long been one of the most popular plants as a salad. It was formerly much used in medicine as a diuretic and anti-scorbutic, but its great consumption now is as an article of diet. As it frequently grows amongst plants that are not wholesome, and that bear to it a general resemblance, it would be well for every one to be acquainted with its characters. The plant most frequently mistaken for it, especially when out of flowers, is the fool's water-cress. [SIUM.] From this it may be always distinguished, and in fact from all other *Umbelliferæ*, by the petioles of the leaves not forming a sheath round the stem. The water-Cress is cultivated to a very great extent in the neighbourhood of London. The plants are placed out in rows in the bed of a clear stream in the direction of the current, and all that is required for their successful growth is replanting occasionally and keeping the plants clear of mud and weeds;

sandy and gravelly bottoms are best. "Some market-gardeners who can command only a small stream of water, grow the water-cress in beds sunk about two feet in a retentive soil, with a very gentle slope from one end to the other. Then, according to the slope and length of the bed, dams are made six inches high across it, at intervals, so that when these dams are full, the water may rise not less than three inches on all the plants included in each. The water, being turned on, will circulate from dam to dam, and the plants, if not allowed to run to flower, will afford abundance of young tops in all but the winter months." (G. Don.) Water-Cresses grown in this way have not so fine a flavour as those from natural streams.—*Eng. Cyc.*

(5595) NASTURTIUM. PALUSTRE is also a native of wet places. It has a fibrous root and small flowers, with the petals only as long as the calyx. The two last are also natives of Great Britain. Other European species are *N. lippizense N. pyrenaicum, N. anceps, N. amphibium, N. fluviatile, N. armoracioides, N. terrestre*, and *N. austriacum.*—*Eng. Cyc*

(5596) NASTURTIUM SYLVESTRE, is a less common species. It is found on river banks and in wet places. It is distinguished from the last by having yellow flowers, and by its petals being twice as long as the calyx.—*Eng. Cyc.*

(5597) NATCHENNY.

Moopoon, Beng.	Mootanny, Maleal.
Ragie, Duk.	Rajika, Tsjettipullu, Sans.
Natchenny, Ragie, Guz, Hind.	Kalwaragoo, Tam.
	Punassa, Tamidaloo, Tel.

The name of a useful and most valuable grain, which is eaten and prized by all classes of the natives of India. It is about the size of mustard seed, and darkish coloured. It is made chiefly into cakes, and is also prepared in several other ways; it has a sweetish taste. It is grown on the Coromandel Coast, and in many parts of the Western presidency.—*Faulkner.* It is the Eleusine corocana of botanists.

(5598) NATRON Carbonate of soda Natron is abundant in the vicinity of Ava, where it is used by the Burmese instead of soap, and they call it "earth soap."—*Mason.*

(5599) NAUCLEA, a genus of Plants belonging to the natural order *Rubiaceæ*. It has a calyx with an oblong tube and a short truncate or 5-toothed limb; the corolla is funnel-shaped, with a slender tube, a naked throat, and 5 spreading oval oblong lobes; the anthers are inclosed, and always shorter than the lobes of the corolla; the capsules are 2-celled, sessile upon the receptacle, but gradually attenuated to the base. The seeds numerous, imbricate, winged, fixed to oblong placentæ, which are adnate to the dissepiment; the embryo is invested in a fleshy albumen. The leaves are opposite, or 3-4 in a whorl, petiolate, or sessile. The bracts wanting at the base of the head of flowers, but with linear paleæ among the flowers, which are crowded and sessile. The species are unarmed trees, rarely shrubs, are natives of India and Africa. There are 37 species of this genus enumerated, all of which are natives of the East, but do not possess any peculiar qualities which entitle them to particular notice.—*Eng. Cyc.*

(5600) NAUCLEA CADAMBA.

Cuddum, Hind.	Rudrakshakamba, Tel.
Vella Cadamba, Tam.	

A noble tree, wood yellow, used for furniture. Travancore 292, Bengal 16, *N. Cadamba*, has bracliate branches; petiolate coriaceous ovate leaves; triangular stipules; terminal solitary peduncles, usually shorter than the heads, which are globose. The flowers are orange coloured, collected into heads about the size of a small apple; the style is white and exserted. The seeds not winged; the leaves from 6 to 10 inches long. Kadumba is the native name of this tree; it flourishes about Calcutta and Malabar, where it grows to be a very large tree, and is ornamental and very useful from the extensive shade it affords.—*Eng. Cyc.* It is plentiful in Kotah Boondee and Mewar, rare in Ajmeer. The wood is soft and fine grained like satin-wood. The flowers are fragrant and are called Kurun-phool "This tree would be highly ornamental in compounds," along with the bukain and neem.—*Genl. Med. Top. p.* 182. This tree grows to a very large size, in the Dekhan where it is common about villages; the fruit is eaten by the natives, who esteem the tree as "holy."—*Riddell.* In Tenasserim this fragrant orange-flowered species of nauclea is sometimes cultivated by the natives. Its large glossy leaves afford a thick and beautiful shade; and, in Indian Mythology, it is one of the four shadow giving trees that grow on mount Meru—viz. the eugenia, the nauclea cadamba, the banyan, and the peepul.—*Mason.*

(5601) NAUCLEA CORDIFOLIA.

Daduga, Tel.	Munja cadamba, Tel.
Keli kadam, Beng.	

A large tree growing abundantly in the mountainous districts of the Peninsula of India, wood yellow, rather close grained. It is used for common purposes, and easily worked, but is best suited for work which is sheltered, bedsteads, &c., being much affected by alternation of dry and wet weather. *N. parviflora*, (neer cadamba) is also frequent in the Western Coast, and is valued for yielding flooring planks, packing boxes, &c. Wight No. 49, Travancore 66-223-288, Palamcottah 242, Bangalore 364.—*M. E. J. B.* This like the foregoing species, grows to be a large tree, it is a native of the mountains of Coromandel, the wood is exceedingly beautiful, its colour is like that of the box tree but much lighter, and at the

same time very close grained, it is to be had of a very large size from one to two feet or more in diameter and is used for almost every purpose where it can be dry; for furniture it answers exceedingly well being light and durable. In timber yards the cumboo which if not the same as the above described, is confounded with this and with Bundaroo at Rajahmundry I found Patseroo, Bundaroo and Cumboo indiscriminately applied. The Bundaroo I suppose is the Boti kadami.—*Rhode. M.S.S.*

(5602) NAUCLEA GAMBIER, of Hunter ('Linnæan Transactions,' vol. ix.) is now *Uncaria Gambier* [UNCARIA.]

(5603) NAUCLEA PARVIFOLIA, has petiolate obovate obtuse leaves, oval stipules, and terminal solitary peduncles; sometimes the peduncles are in triplets, when the middle one is the shortest. It is a native of the East Indies and all the coast of Coromandel, but chiefly in the mountains of the Philippines. The flowers are light yellow and globular, about the size of a plum. The wood is of a pale chestnut-colour, firm, and close-grained: it is useful for purposes where it can be kept dry, but when exposed to wet it soon decays.—*Eng. Cyc.*

(5604) NAUCLEA PARVIFLORA. *Rubiaceæ* Ill. 123.

Neer codumbay, ENG.	Bota Kadami, TEL.
Neer codumbai, TAM.	

Grows to be a large tree: is a native of almost every part of the coast of Coromandel but chiefly up amongst the mountains. The wood is of a light chesnut color firm and close-grained, is applied to various purposes where it can be kept dry, but exposed to wet it soon rots.—*Rohde M.S.S.* This is a strong fine grained timber, sustaining a weight of 400 lbs. Beams of considerable size are procurable. The wood is dark colored and close-grained, but according to Roxburgh, soon rots if exposed to wet. From the fineness of its grain it seems well fitted for cabinet purposes, and has the advantage of being easily worked. —*Wight.*

(5605) NAUTILIDÆ, OR NAUTILACEA, a family of Cephalopodous *Mollusca*. According to Lamarck, they constitute the sixth family of his Polythalamous *Cephalopoda*, consisting of the genera *Discorbites*, *Siderolites*, *Polystomella*, *Vorticialis*, *Nummulites*, and *Nautilus*. To these Mr. G. B. Sowerby, Jun., adds *Simplegas* and *Endosiphonites*. In the system of M. De Blainville it is the fifth family of his *Polythalamacea*, and comprises the genera *Orbulites*, *Nautilus*, *Polystomella*, and *Lenticulina*. The genus *Nautilus* is the type of this family. The species inhabit the seas of warm climates, especially those of Asia and Africa, and their islands, Amboyna, Zanzibar, and New Guinea; and the Pacific and Australian Oceans.—*Eng. Cyc.*

(5606) NAVANE (Can.) is grown in very few places in Mysore, and serves as food for poor people.—*M. E. Cat.*

(5607) NAVILE. Oil seeds of Bassia latifolia.

(5608) NEATS FOOT OIL. At the Madras Exhibition of 1855, this was exhibited by the Madras Tariff—Tanjore Local Committee and Lieut. Hawkes. Its uses as a softener of leather, &c. &c. are well known.

(5609) NEEDLES.

Sooee, GUZ. HIND.

Are well-known useful articles, made from the best steel, and reduced by a wire-drawing machine to a suitable diameter. Dr. Ure states that, "the construction of a needle requires "about 120 operations; but they are rapidly, "and uninterruptedly successive."

(5610) NEEL. INDIGOFERA TINCTORIA.

Neelum, TAM.

(5611) NEEMOOKA. Root of several species of Cissampelos.—*Ben. Phar.*

(5612) NEERADI MOOTOO. Species of JATROPHA.

(5613) NEERADI MOOTOO OIL.

Neerada Mootoo Yennai, TAM.	Junglie Badam ka Tel, HIND.

This valuable oil was sent to the Madras Exhibition under the various names of Neeradee-mootoo, jungle Almond, Maroty, Tamana, Maravettie, Neervettie and Soorty. It is said to be in great repute, as a medicine amongst native practitioners and the kernel enters largely into their prescriptions. It might probably be found of use in the arts, it much resembles almond oil but is rather thicker. The seeds cost in Madras As. 2-6 per seer—excellent specimens were contributed by the Madras Tariff, Travancore and Cochin Local Committees and Lieutenant Hawkes.

(5614) NEERIJA BARK. Bark of Elæodendron Roxburghii—*Ben. Ph.*

(5615) NEEROODEE.

Chinna neeroodee, TEL.	Neeroodee, HIND.

(5616) NEILGHERRY GRASS. This is a species of lobelia, which is unknown on the Neilgherries, its name notwithstanding, and probably came from Java. Wight, writing on the lobelias says: "There is a small cespitose species much cultivated in pots, by amateurs, under the strange name of Neilgherry grass. I suspect the *Lobelia succulenta* of Blume, a Java plant."—*Mason.*

(5617) NEILGHERRY NETTLE; HOROO SURAT OF ASSAM. Urtica heterophylla.

Herpah or Serpah, BHOOTEA.	Theng Mah, CHINESE.

Is the most widely diffused of the large Indian Nettles, being found in South Concan, along the Malabar coast; the Mysore, the Neil-

gherries, the valleys of the Himalayas in Assam & Burmah. It is an annual plant, the sting of which produces intense pain, the bark abounds in fine, white, glossy silk like fibres, but these probably differ with the locality in which the plant is grown. Dr. Wight describes those of the Neilgherries, as a fine soft flax like fibre, and fitted to compete with flax in the manufacture of even very fine textile fabrics. The Todawars extract it by boiling the plant, and use it as a material for making thread. Mr. Dickson passed it through his machine and liquid, which rendered it like a beautiful, soft, silky kind of flax. He calls it a wonderful fibre, of which the tow would be useful for mixing with wool, as has been done with the China grass.—*Royle.*

(5618) NELUMBIACEÆ, a natural order of Exogenous Plants, by some writers associated with *Nymphæaceæ*, or Water-Lilies, which they resemble in appearance and manner of life, inhabiting the fresh waters of the temperate parts of the world, and producing large polypetalous flowers with numerous stamens. But these orders differ in such important circumstances that they can hardly be regarded as plants of very close alliance, much less as members of the same order for *Nelumbiaceæ* have no albumen, and their system of female organs is broken up into its original elements, while in *Nymphæaceæ* there is an abundance of albumen, and the female system is completely consolidated. *Nelumbiaceæ* are readily known by their carpels being distinct, 1-seeded, and buried in the cavities of a large truncated fleshy receptacle, which eventually forms a broad hard bed, filled with holes, in each of which there is a single ripe nut. Notwithstanding their large flowers, these plants must be regarded as among the lowest forms of the exogenous type. The best known species is *Nelumbium speciosum*, a magnificent water-plant floating in the rivers and ditches of all the warmer parts of Asia, and also found in the Nile: its nuts are supposed to have been the sacred bean of Pythagoras; its fleshy stems are used as food by the poorer inhabitants of China. The nuts of all the species are eatable and wholesome. *Nelumbium* is the only genus. —*Eng. Cyc.*

(5619) NELUMBIUM, a genus of Plants belonging to the natural order *Nymphæaceæ*, but sometimes regarded as the type of an order called *Nelumbiaceæ*. It has many distinct carpels, half-immersed in the profoundly honey-combed obconical elevated torus, each bearing a style with a solitary seed in each carpel, which is exarillate, and destitute of albumen. The flowers are large and showy, white, red, or yellow. Both leaves and flowers rise from the surface of the water.—*Eng. Cyc.* Writing regarding the Nelumbium, Mr. Fortune says I now walked down to the lake accompanied by the priests. No flower could be more beautiful or more majestic than the Nelumbium was at this season. As I stood on the little romantic bridge I looked to the right and left; my eye rested on thousands of these flowers, some of which were white, others red, and all were rising out of the water and standing above the beautiful clear green foliage. The leaves themselves, as they lay upon the smooth surface of the lake, or stood erect upon long footstalks, were scarcely less beautiful than the flowers, and both harmonized well together. Gold, silver, and other kinds of fishes were seen swimming swiftly to and fro, and apparently enjoying themselves under the shade of the broad leaves, in happy ignorance of the encounter between their protectors and their piratical enemy.—page 350. At another place he says, in the garden of a mandarin at Ning-po. I once observed a very beautiful variety of the Nelumbium, different from the red and white kinds already noticed, and which I may distinguish by the name of *N. vittatum*, its flowers being finely striped. It was evidently extremely rare in that part of China, so rare indeed that I could not succeed in procuring a plant to send to England.—page 351. Although these plants are generally grown in the stove when their cultivation is attempted in England, they are fitted by nature to endure a very low degree of temperature in winter. They are abundant in all parts of the province of Kiang-nan, at Shanghae, Soochow, and Nanking, where the winters are very severe. The ponds and lakes are often frozen up and the thermometer frequently sinks to within a few degrees of zero. During the spring and summer months the plants form and perfect their leaves, flowers, and fruit; in autumn, all the parts which are visible above water gradually decay and nothing is left in a living state except the large roots, which remain buried deep in the mud, and they continue in a dormant state until the warmth of spring again calls vegetable life into action. p. 351. The Nelumbium, or *Lien-wha*, is cultivated very extensively in China for the sake of its roots, which are esteemed an excellent vegetable, and are much used by all classes of the community. The roots attain their largest size at the period when the leaves die off; and are dug up and brought to market during the winter months in the north of China. The stalls of the green grocers are always loaded with them at that season of the year. Although in high repute amongst the natives, being served up with many of their dishes and forming part of others, I must say that I never liked them, nor are they generally liked by foreigners. An excellent description of arrowroot is made from them, which is considered equal in quality to that which England imports from the West Indies. The seeds are also held in high estimation; they are commonly roasted before being served up to table.—*Fortune, pag* 352.

(5620) NELUMBIUM SPECIOSUM. Juss. EGYPTIAN LOTUS. The Plant.

Tawmaray, TAM. | Kumala also Padma, Kungwel, DUK. | SANS.

(5621) NELUMBIUM SPECIOSUM, PYTHAGOREAN BEAN, has a polypetalous corolla, and anthers drawn out beyond the cells into a club-shaped appendage. It is a native in slow running streams and tranquil waters, in the warmer parts of Asia. The flowers are very beautiful, smelling of anise, and generally of a rose colour, seldom white. A variety of this species, Tamara, has its outer stamens sterile, dilated at the top, winged, obcordate, the appendage rising from a notch at the apex. It is a native of Malabar. The fruit resembles an instrument once used in play by the French, called Lotos, and is one of of the plants supposed to be the celebrated Lotos of antiquity, formerly found in Egypt. It was known to the Greeks, and is mentioned as growing in Egypt by Herodotus (ii. 92), Theophrastus, and others. Although not now to be met with in that country, there can be no doubt as to its having actually existed there, either naturally or in a cultivated state, for these authors speak of it in clear and decisive terms, and their accounts are confirmed by the sculptures still preserved, which testify that this species, as the proper Lotos, has obtained religious reverence. It is spoken of as having been used as food by the Egyptians. Both roots and seeds are esculent, and are accounted cooling and strengthening, and to be of service in extreme thirst, diarrhœa, vomiting, &c. In China it is called Lien-wha, and the seeds and slices of the hairy root, with the kernels of apricots and walnuts, and alternate layers of ice, were frequently presented to the British ambassador and his suite, at breakfasts given by the principal mandarins. The roots are laid up by the Chinese in salt and vinegar for winter use. Thunberg says this plant is held sacred in Japan, and is considered pleasing to the deities, the images of which are frequently made sitting on its large leaves. The seeds are somewhat of the size and form of an acorn, and of a state more delicate than that of almonds.—*Eng. Cyc.* This beautiful plant, which floats on the surface of the water, is well known to be highly venerated by the Hindoos " but it is the more immediate attribute of vishnoo, " from being the prime of aquatic vegetables, and he a personification of water." It is also peculiarly sacred to Lakshmi, the wife of Vishnoo who is sometimes called Kamala, or Lotus-like: it is moreover, an emblem of female beauty. This plant is the true Lotus of the Egyptians, and the Nymphœa Nilufer of Sir William Jones, Nilufer being its Arabic name. The new blown flowers of the rose coloured Tamaray have an agreeable fragrance; those of the white and yellow have less odour.

There is a variety which is blue, a native of Cashmere and Persia.—*Ains. Mat. Med. p.* 162. This grows at Lahore and in Cashmere. Its flowers, which are abundant on the lakes, are used by the Hindoos in their religious ceremonies called Pooja. Every morning I saw, at Cashmere, vast numbers of these flowers, which had served in the rites of the Pooja, flowing down the river. Its boiled roots are eaten as a pot-herb by the natives; in Lahore they are called Pe, in Cashmere Nadroo. Nelumbium seeds are also employed as articles of diet amongst the natives of India; I believe they are the same kind of seeds as those from which the ancient Egyptians made a sort of bread.—*Honigberger, p.* 315. Several aquatic plants increase the list of Chinese plants among which the nelumbium covers extensive marshes in the eastern and northern provinces, otherwise unsightly and barren. The root is two or three feet long, and pierced longitudinally with several holes; when boiled it is of a yellowish color and sweetish taste not unlike a turnip. Taro is used less than the Nelumbium, and so are the watercaltrops and water-chestnuts. The taste of watercaltrops when boiled resembles that of new cheese, water-chesnuts are the round roots of a kind of sedge and resemble that fruit in color more than in taste, which is mealy and crisp. The sweet potatoe is the most common tuber for although the Irish potatoe has been cultivated about Canton and Whampoa for scores of years, it has not become a common vegetable among the people.—*Williams' Middle Kingdom, Vol.* II. *page* 44.

(5622) NELUMBIUM SPECIOSUM: Juss. ROOT OF THE PELTATED WATER LILY. Wild.

The Root.

Tawmaray Kalung, TAM. | Bekhiniloofur, PERS.
Kungwelka gudda, HIND AND DUK. | Sahastraputra, SANS.

This is an esculent root and is also prescribed medicinally as cooling and demulcent. See Hort. Mal. Part xi. page 60.—*Ains. Mat. Med. p.* 117. The roots of the sacred bean of India after being cut into slices, dried and fried in oil, are eaten by the natives and considered a delicacy.—*Jaffrey.*—This is the root of a plant highly venerated amongst the Hindoos. It is dressed in different ways by the natives but like the Allie Kalung, it is only to be obtained during very dry weather as it grows in the beds of tanks. 1st Section 4th.—*Ainslie, p.* 251. Nelumbium Speciosum, the Large water lily, grows wild in tanks, in all parts of India.

(6623) NELUMBIUM SPECIOSUM. SACRED BEAN PLANT. The Flower. The flower of this plant being much like a white lily, it is usually regarded as one, but the fruits are so different that botanists have placed them in different natural families.—*Mason.*

(5624) NELUMBIUM SPECIOSUM. THREAD of the EGYPTIAN LOTUS.

Tawmaray noole, TAM. | Padma, SANS.
Tawmaray darum, TEL.

Tawmary noole is the name given by the Tamools to the long, fine filaments which are found within the cells of the stalks of the sacred Tamaray plant. With them are prepared those wicks which on great and solemn religious occasions are burnt in the lamps of the Hindoos placed before the shrines of their deities. Other wicks of a similar nature but less venerated are made with the filaments of the Allie (Nymphæa Lotus) and also from those of the Shengalaneer, (Nymphæa odorata); the delightfully smelling flowers of which are held in high estimation by the Indians.—*Ains. Mat. Med. p.* 202.

(5625) NEMESIA FLORIBUNDA, SCROPHULARIACEÆ. These plants may be cultivated from seed in any rich light soil, the colour of the flowers is purple.—*Riddell.*

(5626) NEMOOKA ROOT, the root of several species of Cissampelos, and is an efficient substitute for Pareira.—*O'Shaughnessy.*

(5627) NEMOPHILA AURITA, HYDROPHYLLACEÆ. These plants are all annuals, and require a great deal of moisture, growing and flowering in shady situations, the colors are white and purple, blue and dark purple, they are natives of California, and North America.—*Riddell. Nemophila Insignis,* and *maculata* are too tender to succeed well on the plains. N. maculata the spotted variety succeeds to a certain extent if sown after the heavy rains are past.—*Jaffrey.*

(5628) NENDOON. Hard, though coarse, open-grained, heavy Ceylon wood.

(5629) NEOPHRON PERCNOPTERUS. Mr. C. J. Anderson, in his interesting work entitled 'Lake Ngami,' notices the curious fact of this Vulturine bird resorting to vegetable food. In the desert sandy region extending southward from Walfisch (*i. e.* 'Whale-fish') Bay, along the eastern coast of South Africa, "a kind of prickly gourd (called, by the natives, *naras*) of the most delicious flavour" occurs in great abundance; the creeping plant that bears it covering almost every little sand-hillock; and moreover fixing, "with wonderful tenacity, by means of its extensive ramifications, the constantly shifting sands:, it is, indeed," remarks Mr. Anderson, "to those parts what the sand-reed (*Ammophila arundinacea*) is to the sandy shores and downs of England. In this barren and poverty-stricken country, food is so scarce, that without the 'naras' the land would be all but uninhabitable. It is not man alone, that derives benefit from this remarkable plant; for every quadruped from the Field Mouse to the Ox, and even the feline and canine races, devour it with great avidity. Birds are, also, very partial to it, more especially Ostriches, who during the 'naras' season are found in great abundance in these parts. *I have seen the White Egyptian Vulture feed upon it.*" Captain Watkins, in a paper on the Ornithology of Andalusia ('Zoologist,' November, 1856), states that he possesses, alive, a common Kite (*Milvus regalis*) and also a Black Kite (*M. ater*). "These birds, in their present domestic state, have a great *penchant* for vegetables and fruits. I have watched them often in my kitchen-garden plucking the pods of peas, and eating the contents; a bed of radishes, also, (which I was at a loss to conceive what had demolished,) I one morning found occupied by my two pets, eagerly devouring them: they could not have been driven to it by hunger, as they were well supplied with birds and young Rabbits. Since the figs and peaches have been ripe, they have indulged most freely in their taste for fruit, nothing pleasing them better than a fig." In the *Annals and Magazine of Natural History*, xii (1843), p. 269, the curious fact is recorded of the Jaguar (FELIS ONCA) striking down and devouring the nests of a honey-producing Wasp of S. America! In a recent notice of the devastations of Locusts in South Africa, we observed the NEOPHRON PERCNOPTERUS designated as the 'Locust-bird'; making its appearance in vast numbers to prey on the destructive insects: but it is not what is ordinarily known as the 'Locust-bird' in that part of the world, which is a much smaller bird, appertaining to the Starling or Maina group. According to Sir James Alexander, as quoted by Mr. Anderson, (and given on the authority of the natives about the Orange river,) when the Ostriches have left their nest in the middle of the day in search of food," "a white Egyptian Vulture may be seen soaring in mid-air, with a stone between his talons. Having carefully surveyed the ground below him, he suddenly lets fall the stone and then follows it in rapid descent. Let the hunter run to the spot, and he will find a nest of probably a score of eggs, some of them broken by the Vulture." We have all heard of the story of an Eagle, or a Gull, or a Crow, (for the anecdote is current of all of them,) dropping the 'shell-fish' upon a stone; and of the bird's mistaking the philosopher's bald pate for one: but here the case is reversed; for the stone is taken up and dropped on the eggs of the Ostrich. In his account of the British Carrion Crow, Mr. Mudie remarks—"There are modern instances of the story of the ancient philosopher who was killed by a Crow mistaking his head for a stone, and dropping an Oyster on it in order to break the shell. One of these was seen by the celebrated Watt. A Crow caught up a crab, rose with it to a considerable height, and dropped it—not on the head of a modern philosopher, or he might have come off more safely than the ancient one,—but on a stone, and descended to her feast." Again, Mr. Selby remarks, of the Hooded Crow, "I have repeatedly observed one

of these birds to soar up to a considerable height in the air, with a cockle or mussel in its bill, and then drop it upon the rock, in order to obtain the contents." Anecdotes of Gulls performing the same feat are recorded in Cabanis' 'Journal fuer Ornitholigie,' Vol. III. (1844-5): so that there is no particular reason to disbelieve the assertion of the NAORHROH dropping a stone on the eggs of the Ostrich.—*Mr. Bligh in Calcutta Review.*

(5630) NEPAL PAPER PLANT. DAPHNE CANNABINA (THYMELÆÆ). At the Great Exhibition of 1851, many were much interested about a huge sheet of Nepal paper exhibited by Colonel Sykes. This was curious, not only on account of its size, but also on account of the plant from which it was made. This belongs to a genus and family containing plants remarkable for their fibrous bark. Thus the Lace-bark tree (*Daphne Lagetta*, now *Lagetta lintearia*) of the West Indies is "remarkable for the beautiful net-like appearance of its several easily separable layers of bark, whence it has received its English name. As the fibres of other species possess considerable tenacity, they have been employed in making cordage; and the toughness, as well as fineness of the inner bark of these plants, may be seen in a plant common in English gardens, and used in medicine on account of its acridity, that is, the Mezereon, *Daphne Mezereum* of botanists. It is from the inner bark of one of these plants, the *D. Bholua* (*D. cannabina* of Loureiro, and which is supposed to be identical with the *D. odora* of Thunburg), which is extremely abundant in the Himalayas, that this Nepal paper is made, as from other species in other countries. Another plant of the same, or of an allied genus, as it is called both *Daphne* and *Gnidia eriocephala*, is very common on the ghauts of the West of India, and in the hilly parts of the Sothern Mahratta country and of the Dukhun. Several specimens, from various localities, are in Col. Sykes's collection. It is probable that it might be turned to the same use as the Nepal plant. Of the uses of this plant good accounts have been given by Mr. Hodgson ('Journ. As. Soc.,' i, p. 8, 1832) and Dr. Campbell. The former describes the process as consisting, first, in boiling slips of the inner bark of the paper plant in a ley of wood-ashes for about half an hour, by which time the slips will be quite soft. These are then beaten in a stone mortar with a wooden mallet till they are reduced to a homogeneous pulp. This is then diffused through water, and taken up in sieves and paper frames, as in the ordinary process for making paper by hand. When dry, the sheet of paper is folded up; sometimes it is smoothed and polished by being rubbed on wood with the convex side of a conch shell: but Mr. Hodgson does not explain how the very large sheets of several yards square are made. Though called Nepalese, the paper is not manufactured in Nepal, but in Cis-Himalayan Bhote, in the mid-t of its immense forests, where there is an abundant supply of the plant, of wood for ashes and for firewood, as well as a constant supply of clean water. This paper is remarkable for its toughness, as well as its smoothness. Some of it, in the form of bricks of half-stuff, was sent to England previous to the year 1829. As the quantity sent was not sufficient for a complete experiment, a small portion of it was made into paper by hand. An engraver, to whom it was given for trial, stated that "it affords finer impressions than any English-made paper, and nearly as good as the fine Chinese paper which is employed for what are called India paper proofs." ('Gleanings in Science,' i, p. 210.) Dr. Campbell decribes the paper, as made by the Bhoteahs, "as strong, and durable as leather almost, and quite smooth enough to write on; and for office records, incomparably better than any India paper. It is occasionally poisoned by being washed with preparations of arsenic, in order to prevent the destruction caused by insects. Many of the books in Nepal, written on this paper, are said to be of considerable age, and that the art of making paper seems to have been introduced about 500 years ago from China, and not from India." He states that this paper may easily be procured at Patna, Purneah and other places in the plains of both Southern and North-Western India.—*Royle fibr. pl. page* 311. The dried bark, of the Nepaul paper plant, may be substituted for the Mezereon (D. Mezereum) of the London Pharmacopœia, the Bazar Mezereon, is almost always inert from age.—*Beng. Phar. page* 279.

(5631) NEPENTHACEÆ, *Nepenths* a natural order of Exogenous Plants inhabiting the damper and warmer parts of Asia, and having in the place of leaves, large hollow bodies furnished with a lid, and containing water secreted from a peculiar glandular apparatus with which they are lined. These bodies, or pitchers, as they are called, appear at the end of a leafy tendril-like expansion of the bark, and are considered to be a hollow state of the apex of the petiole of a leaf, while the lid that closes them is regarded as the blade. Their flowers are dioecious, green or brown, apetalous, arranged in cylindrical racemes, and are succeeded by a capsular fruit filled with fine fusiform seeds, which look liked very small sawdust. They are considered to be closely akin to *Aristolochiaceæ*, and also related to *Sarraceniaceæ* and *Euphorbiaceæ*. Adolph Brongniart has pointed out a resemblance between *Nepenthaceæ* and *Cytinaceæ*; but Lindley remarks that it is impossible to agree in this conclusion:—"To say nothing of the extreme dissimilarity in habit between these plants, the structure of their fruits appears to be essentially different; and the seeds of *Cytinus* being unknown, the resemblance between it and *Nepenthes* is reduced to a similarity in the arrangement of the anther swhich cannot

in the present case be considered of much importance, as it in some degree depends upon the unisexuality of the flowers of both genera. A better approximation of the order has been made by Brown, who points out a relation to Birthworts (*Aristolochiaceæ*); as to which, the structure of the wood in some respects confirms his views. Like many in that order it is zoneless, although plainly exogenous; but it has this in particular to characterise it, that the system of spiral vessels is developed in a degree unknown in any other plants. Endlicher adopts the same view as does A. Bronginart, and I have formerly coincided with these botanists; but the adherent ovary of Birthworts, their highly-developed calyx, axile placentation, and hermaphrodite flowers, are serious difficulties in the way of a close contact between them and Nepenths, unless the peculiar structure of the wood, the consideration of which I for the present abandon should lead to the final establishment of the class of Homogens, in which case Nepenths and Birthworts will be brought into contact or at least, near neighbourhood. For the present the true position of this order must be regarded as an undetermined point." Lindley places them in the Euphorbial alliance, observing that "its points of agreements are its unisexual flowers, albuminous seeds, incomplete floral envelope, and climbing habit. Its great disagreement consists in its indefinite seeds and peculiar woody structure, which is however in some respects without example." ('Vegetable Kingdom.') The water found in an unopened pitcher was found to emit while boiling an odour like baked apples, and to yield minute crystals of superoxalate of potash. There are about six species of *Nepenthes*.

(5632) NEPENTHES. The pitcher-plant grows on strong and grassy hills about Amwee, near the Jyntea Hills and crawls along the ground; its pitchers seldom contain insects in the wild state, nor can we suggest any special function for the wonderful organ it possesses.—*Hooker, Him. Jour. Vol.* 11. *page* 315. There are about six species of Nepenthes, the best known of which, the Pitcher plant, is the N. Distillatoria. The Nepenths, *Nepenthaceæ*, is a natural order of exogenous plants, inhabiting the damper and warmer parts of Asia, and have in the place of leaves, large hollow bodies furnished with a lid and containing water secreted from a peculiar glandular apparatus with which they are lined. These bodies, or pitchers as they are called appear at the end of a leafy tendril-like expansion of the bark and are considered to be a hollow state of the apex of the petiole of a leaf, while the lid that closes them is regarded as the blade.—*Eng. Cyc.*

(5633) NEPHELIUM LITCHI, Sapindaceæ. This tree, orginally from China, is an ever-green, and grows to a large size. The fruit is of a dark brown color, and contains a glutinous yellow sweet sort of pulp; it is not much prized—perhaps from its inferior quality to the Chinese fruit, which is much esteemed. The fruit ripens in March and April.—*Biddell.*

(5634) NEPHELIUM. Red Nephelium. This is a small inferior Tenasserim fruit, eaten by the natives only, though belonging the same genus which produces the famous lichi, and bearing its fruit in bunches like that.—*Mason.*

(5635) NEPHELIUM. Wild Ramboutan. One of the indigenous trees of Tenasserim bears a fruit whose subacid is very agreeable to the palate, and much resembles that of the ramboutan so famous at Malacca. Malays, to whom I have shown the fruit, say it is the wild ramboutan, and the tree certainly belongs to the same genus; but never having met with it in flower, I cannot determine the species.—*Mason.*

(5636) NEPHRITE.—*Jade* or *Axe-Stone*—a mineral which occurs in masses. The structure is compact. Its fracture is coarse, splintery. Hardness 7·0. It is very tough. Colour dark-green and green of other shades. Translucent on the edges. Specific gravity 2·9 to 3. Before the blow-pipe it whitens, but does not fuse, but with borax it forms a transparent glass. The following is an analysis by Kastner:—

Silica	50·50
Alumina	10·00
Magnesia	31·00
Oxide of Iron	5·50
Oxide of Chromium	0·05
Water	2·75
	——99·80

It is carved into images and worn as a charm. It was supposed to be good in diseases of the kidney—hence its name. It is found in New Zealand, China, and Western America.—*Eng. Cyc.*

(5637) NEPHRODIUM FILIX, Mas. A Filix Mas.—*Honigberger.*

(5638) NERITA, a genus of Gasteropodous *Mollusca*, the type of the family *Neritidæ*. The genus *Nerita* has the following characters:—Shell thick, smooth, or spirally grooved; epidermis horney; outer lip thickened, and sometimes denticulated within; columella broad and flat, with its inner edge straight and toothed; operculum shelly. Dr. J. E. Gray makes the *Naticidæ* the first family of his second section, *Eriophthalma* (*Edriopthalma?*), of his second order *Phytophaga*. Under the *Naticidæ* he comprises the following genera:—*Natica, Neverita, Nacca, Cepatia, Polinices, Mammilla, Cernina, Globulus, Naticina, Cryptostoma, Stylina*, (?), *Radula* (?), and *Neritopsis*. In Woodward's 'Manual of the Mollusca' the *Naticidæ* inclued the genera *Natica, Sigaretus, Lunellaria, Narica*, and *Velutina*. Ninety recent species of *Natica* have been recorded. They are inhabitants of the Arctic

Seas, Great Britain, the Mediterranean and Caspian Seas, India, Australia, China, Panama, and the West Indies. The fossil species amount to 260.—*Eng. Cyc.*

Sigaretus has 26 recent and 10 fossil species.
Lamellaria has 3 recent and 2 fossil species.
Narica has 6 recent and 4 fossil species.
Velutina has 4 recent and 3 fossil species.

In Forbes and Hanley's 'British Mollusca' the following species of *Neritidæ* and *Naticidæ* are enumerated as British:—*Neritina fluviatilis*, *Natica monilifera*, *N. nitida*. *N. sordida*, *N. Montagui*, *N. Helicoides*, *N. pusilla*, and *N. Kingii*.

(5639) NERITIDÆ, a family of Holostomatous *Gasteropoda*, having the following characters:—Shell thick, semi-globose; spire very small; cavity simple from the absorption of the internal portion of the whorls; aperture semi-lunate; columellar side expanded and flattened; outer lip acute; operculum shelly, sub-spiral, articulated. At the end of the columella there is an oblong muscular impression, connected on the outer side by a ridge on which the operculum rests; within this ridge the inner layers of the shell are absorbed. Animal with a broad short muzzle, and long slender tentacles; food oblong, triangular; teeth 7, uncini very numerous. This family includes the genera *Nerita*, *Pileolus*, *Neritina*, and *Navicella*. Mr. Swainson places the family *Naticidæ* between his *Turbidæ* and *Trochidæ*, making it consist of the following sub-families and genera. His arrangement is, he says, founded on the shells only, from ignorance of the animals of the major part:—

Sub-Family 1. *Naticinæ* Sea-Snails.

Genera: *Natica*, Lam. (with the sub-genera *Naticella*, *Globularia*, *Mamillaria*, *Sigaretus*, *Naticaria*, *Lacuna*, *Leuctis*).

Sub-Family (?) *Neritinæ*. Nerits.

Genera: *Nerita*, Linn. (with the sub-genus *Neritopsis*, Gray); *Neritina*, Lam. (with the sub-genera *Clithon*, *Velotes* (*Velates*), *Pileolus*, and *Navicella*). ('Malacology.') Dr. J. E. Gray makes the *Neritidæ* the sixth family of his *Podophthalma*, and places it between the *Fissurellidæ* and the *Ampullariadæ*. Dr. Gray's *Neritidæ* comprise the following genera:—*Nerita*, *Pileolus*, *Culana*, *Neritina*, *Clithon*, *Dostia*, *Velates*, and *Navicella*. The genus *Nerita* is described separately. [NERITA.]

Neritina has the shell rather thick at the aperture, but extensively absorbed inside; outer lip acute, inner straight, denticulated; operculum shelly, with a flexible border; slightly toothed on its straight edge.

Pileolus has the shell limped-like above, with a subcentral apex; concave beneath, with small semilunar aperture, and a columellar disc, surrounded by a broad continuous peristome. The species are only known as fossil. Upwards of 100 recent species of *Nerita* and 70 species of *Neritina* have been described. The fossil species of *Nerita* amount to 60, and of *Neritina* to 20. *Nerita* is found in the Lias, and *Neritina* in the Eocene Formation.

Navicella.—With the exception of the disposition of its operculum and of the muscles of attachment to the shell, the animal may be said to be nearly similar to that of *Nerita*.

The genus *Natica*, sometimes made the type of a family (*Naticidæ*), has been included with the *Neritidæ*. Messrs. Quoy and Gaimard remark, that the *Naticæ* are animals to which their foot gives a remarkable aspect. It is a long oval lamella, ordinarily squared in front, oval behind and doubled; anteriorly, where it is widest, it is a thick escutcheon, a little auriculated, which ascends on the front of the shell, which it covers, at the same time that it hides all the head of the animal, of which ordinarily nothing but the tentacles appear; a groove on each side indicates the two parts of the foot.

Natica Melanostoma has the shell oval, ventricose, convex-depressed thin, white, zoned with yellow; spire somewhat prominent; lip blackish-brown, umbilicus semi-closed. (Lam.) Length 15 lines; breadth 11½ lines. Operculum membranous; paucispiral on the left border; the rest of its lamellæ obliquely transverse. Colour deep chestnut-brown lighter on the edge. It has been found at Tonga, the Moluccas, and many other places. Found by Messrs. Quoy and Gaimard some fathoms deep. Species of the genus have been captured creeping on the shore like the Nerits on rocks and sea weed, and from the surface to the depth of 40 fathoms on mud and sandy mud, in æstuaries and in tidal rivers.—*Eng. Cyc.*

(5640) NERIUM (from *νηρός*, humid, the habitat of the species), a genus of Plants belonging to the natural order *Apocynaceæ*. It has a hyprocrateriform corolla, the orifice surmounted by lacerated multifid processes; segments of the limb contorted; the filaments are inserted into the middle of the tube; the anthers sagittate, adhering by the middle to the stigma; it has two ovaries, a filiform style dilated at the apex, and an obtuse stigma.—*Eng. Cyc.*

(5641) NERIUM ANTIDYSENTERICUM. (OVAL LEAVED) ROSEBAY TREE. *Apocynaceæ*. Linn. *Wrightia Antidysenterica*.

Veppalei maram, TAM. | Indurjan, HIND.

This common shrub flowers in April and May in terminal corymbs. The bark is used as an astringent.—*Riddell.* The wood of this tree is white beautiful, and fine grained; and is made into cabinets and elegant furniture.—*Ains. Mat. Med. p.* 209. Wight speaking of the Tamul-

name says I take this name from Ainslie, but suspect it is another name for Kooda pallie, (which see) the Linnæan name belonging to a Ceylon plant, which I have not seen on the continent. The wood is said to be excellent for cabinet making purposes.—*Wight.* A shrub common in many parts of Hindostan. Its seeds bear some resemblance to oats, and are officinal at Lahore. They certainly merit the attention of European physicians, as they possess many medical properties.—*Honigberger, p.* 316.

(5642) NERIUM COCCINEUM, Scarlet Oleander. *Wrightia coccinea. Nerium coccinea.*

Scarlet Oleander, Soorookhkanel, Hind.

Common in gardens at Ajmeer and it is highly ornamental.—*Gent. Med. Top. p.* 186. In Tenasserim European compounds are occasionally scented with this useful shrub, whose orange-red flowers have the grateful fragrance of the pine apple.—*Mason.*

(5643) NERIUM GRANDIFLORUM.

Mendasinghi, Hind.

Double species cultivated by seed or cuttings.—*Riddell.*

(5644) NERIUM ODORATUM. Oleander.

Aralivayr, Tamil.	Ghennera vayroo, Tel.
Cauner kajurr, Duk.	Karrabeera, Sans. *Ainslie.*

This species has linear lanceolate leaves, three in a whorl; the segments of the calyx erect; appendages of the corolla filamentous; the anthers bearded at the point. The flowers red or white, with an agreeable musky scent. The bark of the root and the sweet-smelling leaves are supposed by native Indian doctors to act as powerful repellants applied externally. The root, taken internally, acts as a poison. (*Eng. Cyc.*), and is frequently resorted to, for the purpose of self destruction by the women of India when tormented with jealousy, the plant is the Beluttry-areli of the Hortus Malabaricus.—*Ainslie's Mat. Med. p.* 70. The root of the hill-plant is much more violent than that of the garden, and in the hills is considered poisonous. Jealous women so frequently have recourse to it that it is proverbial among the females of the hills, when quarrelling, to bid each other go and eat of the root of Kaneer.—*Honig, p.* 316. It is plentiful and very beautiful at Ajmeer. The single white is called sufaid-kurpud, the single rose-colored, lal-kurpud and the beautiful large double rose variety is called pudma-kurpud.—*Irvine, p.* 186.

(5645) NERIUM ODORUM. This well known fragrant flower adorns a few of the gardens in Maulmain, but it has not yet come into general cultivation.—*Mason.* It is cultivated in the gardens at Lahore, merely for its beauty. Its flowers, leaves, and roots, are officinal.—*Honigberger, p.* 326.

(5646) NERIUM OLEANDER.

Kar-Zubra, Hind.

Common Oleander, has lanceolate leaves, three in a whorl being beneath, the segments of the corona trifid. It is a native of the Indies, in humid places, but has now become wild in the south of Europe, by the side of streams and the sea-coast. The flowers are rather large and of a bright-red colour. This species contains a great quantity of gallic acid, and a decoction of the leaves or bark forms an acrid stimulating wash, much employed by the poor people in the south of France to cure cutaneous disorders. The peasants in the neighbourhood of Nice use the powdered bark and wood of the Oleander to poison rats. Several cases are also recorded of death from having eaten meat roasted on a spit of Oleander wood. All the species of Oleander are very showy when in blossom. They thrive well in a light rich soil; and cuttings strike root freely in a moist situation. All of them require a good deal of heat to flower well in this country. (Don, *Dichlamydeous Plants*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany.*)—*Eng. Cyc.* In the Dekhan, the Double Red and White grow wild on the banks of rivers, bearing both white and red flowers: the root is poisonous. There are two other varieties very commonly met with bearing double flowers both red and white, and by budding the red color on the opposite one in several parts of the same stalk, a very pretty appearance may be given to the shrub. The yellow congener is called the Exile—introduced I believe from America. Grows easily from cuttings.—*Riddell.*

(5647) NERIUM PISCIDIUM. Among the division of plants to which the Apocynaceæ belongs there are some which are most conspicuous for the strength of their fibres. These belong to two families of plants which are so nearly allied to each other, that they were united together by the celebrated Jussieu. Both are remarkable for abounding in milk juice; and some of them in caoutchouc, or some analogous products. Of these, the Apocynaceæ or Dogbanes are composed chiefly of trees and shrubs, of which the Oleander is a conspicuous example. But some are herbaceous, as in the case of the Vinca, or Periwinkle as it is called, which shows another characteristic, that is, the climbing habit of many of these plants, as well as the toughness of their fibre, as may easily be ascertained by trying to break any of the long, trailing twigs of this plant, so common in gardens and shrubberies. Among these, is a plant called *Nerium piscidium*, by Dr. Roxburgh, 'Fl Ind.,' ii, p. 7, common in the Khasya or Silhet Mountains, and

there called *Echalat*. It there forms an extensive perennial climber. Its bark contains a large quantity of fibre, which the natives use for the same purposes as Hemp. Dr. Roxburgh, in steeping some of the young shoots in a fish-pond, in order to facilitate the removal of the bark and to clean the fibres, found that many, if not all the fishes, were killed. Hence the specific name which he applied. Dr. Wight has formed the plant into a new genus, Echaltum. It is probable that there are many other fibre-yielding plants in this family.—*Royle Fib. Pl. p.* 302.

(5648) NERIUM TINCTORIUM, WRIGHTIA TINCTORIA. ROSEBAY, BLUE DYEING ROSEBAY Roxb.

Pala mom also Palak, and Palavayraynoo, TAM.	Tshil aukaloo, TEL. Ulayamaraka, SANS.

This species of Nerium which has been so accurately described by Dr. Roxburgh in the 1st Volume of the Oriental Repertory differs but in a very slight degree from the Nerium Antidysentericum already mentioned and chiefly, by the latter wanting a nectarium. I find that the Indigo (0) yielding property of its leaves is well known to the Natives in many parts of lower India, and that particularly in Coimbatore, near Palachy much blue-dye is actually made from them. Sir William Jones informs us, in the 4th Volume of the Asiatic Researches, that the Hindoo peasants of Bengal call this plant Nil (or Blue); a proof that they are perfectly acquainted with its peculiar qualities.—*Ains. Mat. Med. page* 195.

(5649) NETS.

Jhall, GUZ. & HIND.

Are rarely a subject of commerce, being almost all manufactured by the fishermen and their families. This seems to be the universal practice. —*Faulkner*. Net making or the art in which the fabric is required to be transparent, but in which the fibres are decussated and retained in their places by knots, that the interstices may retain their form and size, and prevent objects from escaping, seems to have been known in the earliest ages in Egypt, and is practised with the greatest skill on the coasts of Bombay and of Scinde, as well as on the rivers of India. A great variety of nets, from a few to fifty fathoms in length, are fully described in the "Illustrated Catalogue." Those from Singapore are interesting, as some are made with cotton, and others with the fibre which is very similar to, if not identical with, that forming the so called China grass.—*Royle Arts &c. of India, page* 505.

(5650) NETTLE, a name applied to various plants. The true Nettles are various species of the genus *Urtica*, well known for their stinging properties, which are owing to the presence of an acrid poisonous secretion that in some Indian species is so dangerous as to cause excruciating pain and even death. Dead Nettles are species of *Lamium*, monopetalous plants belonging to *Labiatæ*, and wholly inert. The Nettle-Trees belong to the genus *Celtis*, also destitute of stinging properties, but having leaves resembling those of some kinds of *Urtica*. [URTICA; LAMIUM.] —*Eng. Cyc.* The great shrubby nettle (*Urtica crenulata*) is common at Chakoong, in Sikkim: this plant, called "Mealum-ma," attains fifteen feet in height; it has broad glossy leaves, and though apparently without stings, is held in so great dread, that Dr. Hooker had difficulty in getting help to cut it down. He gathered many specimens without allowing any part to touch his skin; still the scentless effluvium was so powerful, that mucous matter poured from his eyes and nose all the rest of the afternoon, in such abundance, that he had to hold his head over a basin for an hour. The sting is very virulent, producing inflammation; and to punish a child with "Mealum-ma" is the severest Lepcha threat. Violent fevers and death have been said to ensue from its sting; but this he very much doubts. The stinging hairs are miscroscopic, and confined to the young shoots, leaf and flower-stalks. Leschenault de la Tour describes being stung by this nettle on three fingers of his hand only at the Calcutta Botanical Gardens, and the subsequent sneezing and running at the nose followed by tetanic symptoms and two days' suffering, nor did the effects disappear for nine days. It is, says Dr. Hooker, a remarkable fact that the plant stinks violently only at this season, I frequently gathered it with impunity on subsequent occasions, and suspected some inaccuracy in my observations; but in Silhet both Dr. Thomson and I experienced the same effects in autumn. Endlicher ("Lindley's vegetable kingdom") attributes the causticity of nettle-juice to bicarbonates of ammonia, which Dr. Thomson and I ascertained was certainly not present in this species.—*Hooker, Him. Jour.* Vol. II. p. 188. It will be remembered that in treating of Hemp, it was stated that it belonged to the natural family of the Nettles, or *Urticeæ*. These are widely diffused throughout both tropical and temperate climates, though they generally occur where there is considerable moisture either of soil or of climate. Though small and herbaceous in Europe, they grow to a gigantic size in the hot moist parts of Asia, and extend from its warm tropical islands, all along the Malayan Peninsula, to the foot of the Himalayas, and along which, and in its valleys, they flourish even near to the banks of the Sutlej. Species are also found around the Neilgherries, and along the Malabar coast to the Concan. Though the flowers of all are inconspicuous, some of the species (as *Urtica pulcherrima*) are remarkable for the beauty of their foliage; one of them (*U. tuberosa*) is distinguished by its tuberous rootstock, which is eaten by some of the natives of India, either in its raw or cooked state Every one, however, knows that the great cha-

racteristic of the Nettles is their sting. Some of the Indian species are remarkable, even among Nettles, for this quality; as, for instance *U. crenulata* and *U. heterophylla*, the latter "a most ferocious-looking plant." Many of the Nettles formerly placed in the genus *Urtica* have been removed to the genus *Boehmeria*, which includes what are sometimes called stingless Nettles. But many of each have long been famous for the tenacity of their fibre. Thus, of the European species, thread and cloth, as also paper, have been made from the fibre of the common Nettle (*Urtica dioica*). So, of the Siberian species, *U. cannabina*, thread and cord is made for the use especially of fishermen. In the Society Islands, also, cord is made with the fibres of *U. argentea*; and in Japan, the bark of the species called *U. Japonica*, is employed in making lines, cordage, and cloth. *Himalayan Nettles.*—Major Swetenham, when writing respecting the Maloo Creeper (*v.* p 296), thus mentions the large Nettle of Gurhwal —which he says is considered by the natives as superior to Bhang, or the true Hemp—"There is another plant that grows in the interior of the Hills from which stronger ropes even than the Hemp are said to be made—I allude to the large Nettle plant. I have seen this growing to the height of fourteen or fifteen feet; the Hill people in preparing ropes from this plant, steep it for *three* days *only* and then strip off the fibre; this is done in a contrary method to the Hemp stripping, *i. e.*, the top of the Nettle is broken off, and the fibre pulled down from the thin end." Capt. Huddlestone in his paper on the Hemp of the Himilayas, mentions also other fibres Among these—"The larger Nettle called *Jurkundaloo, Kundaloo* and *Kubra*, grows chiefly in the northern parts of the district, in great quantities; it also grows in the middle ones; and from its fibre the natives make rope for tying up their cattle and snow-sandals. One bundle will produce about a seer of fibre, but it is not collected for sale. The plant grows about eight or nine feet high, and the stalks are about the size of a finger in thickness. It is cut in the cold season, and the stalks are soaked a few days in water before the fibre is stripped off from the thick end like Hemp."—(' *Trans. Agri-Hortic. Soc.*,' viii. *p.* 275.) Dr. Campbell also mentions the gigantic stinging Nettle of the Nipal and Sikkim Hills, as made into Hemp and used in making the cloth called "Bangra." The preparation is the same as the "Pooah." The Bangra is harder and stiffer than the "Pooah," and not adopted to making cordage and nets.

Mr. C. Gubbins, C. S., when at Simla, forwarded some specimens of fibrous material produced by a species of Urtica growing about and below Simla, used by the natives of those parts for making string. The process, which he describes as employed for separating this fibre, is interesting from its simplicity. The plant is cut in October, and dried in the sun; when brittle it is beaten, and the fibres separate easily. He observes: "Seeing it stated that there was considerable labour required in cleaning the fibre, I made particular inquiries on this head; and as far as I can learn, there is no greater trouble in cleaning the fibre of the Urtica when merely dried, than is experienced with the Hemp of the Hills which is not rotted in water." Hence the separation would seem to be effected entirely by the dry process and mechanical means. Capt. Rainey, when Assist. Pol. Agent at Subathoo, sent a net formed from the fibre of Stinging Nettle, which grows in the same locality as that described by Mr. Gubbins, and he says; "1*st*. The Nettles from which this sample was wove, grew in the low valleys adjacent to the Hill station of Simla in the Himalaya Mountains. "2*d*. The vegetable abounds in all the ravines and valleys of those mountains, and forms one of the most rank weeds of these places, during the rainy months. "3*d*. In August and September, when it is in perfection, it can be obtained in any quantity, running from five to six and seven feet in height. "4*th*. As far as I have been able to ascertain, it is chiefly in demand, if not at present wholly so, for fishing nets; in consequence of the virtue ascribed to the cord wove from it, of gaining increased strength by constant immersion in water, and resisting decay from that element longer than any other description of cords. "5*th*. The weed is known throughout the lower and centre ranges of the Himalayas by the names Babar, or Allow, or Bichoo; the last evidently consequent on its stinging property being the common designation of the scorpion. "6*th*. The following is the preparation to which the article is subjected by the natives of the place; but I doubt not, much of the process might be omitted or simplified—"1*st*. Being cut in August or September, the weed is exposed for *one* night in the open air. "2*d*. The stalk is then stripped of leaves and dried in the sun. "3*d*. When well dried it is deposited in an earthen pot which contains water mixed with ashes (the refuse remains of any wood fire), and boiled four and twenty hours. "4*th*. The stalk thus boiled is then taken to a stream and well washed. "5*th*. The Hemp is then brought home, and being sprinkled with flour (otta) (of the grain called Koda), it is again dried in the sun, and afterwards spun at any time into cord for nets of every description." As no distinctive characters are given of these Nettles, it is impossible to determine the respective species. In Gurhwal and near Simla, *Urtica virulenta* and *U. heterophylla* are common as stinging Nettles, as well as some others, while of species of Boehmeria, the *B. frutescens*, *macrostachya*, *Goylodo*, *salicifolia*, are found, and all probably abound in fibre, though a few only

have been as yet ascertained to do so, as has been mentioned in the preceding pages.—*Royle Fib Plants.*

Nettle of Gurwal, grows there to the height of 14 or 15 feet and is used by the Hill people in making ropes.

Neilgherry Nettles.—The *Girardinia Leschenaultiana*, is frequent all over the higher range of the Neilgherries: the bark yields a fine, strong, white flax-like fibre, which the hill people obtain by plunging the plant in hot water, to deprive it of its virulently stinging properties, and then peeling the stalks. The textile material so prepared is of great strength, and the Todawars use it as thread.

Nettle Fibre of the Neilgherry.—From Urtica Heterophylla, is supposed, to be still unknown in commerce. As yet it is only obtainable in small quantity but if called for, the supply might be largely increased as the plant is abundant and widely distributed over the Indian Peninsula. Is is separated by boiling the stalks. —*M.C.C.*

Nettle of the Boehmeria. See Boehmeria.

Strength of the Rheea and nettle Fibres. With regard to the strength of Nettle fibres, it has already been stated that Dr. Roxburgh found the Rami or Caloee bore 240 lb., when Hemp bore 158 lb. and Sunn 150 lb., Messrs. Sharp, in 1815, found a cord bore 252 lb, when Russian Hemp was only required to bear 82 lb. So in Dr. Royle's experiments with these fibres in an untwisted state, Petersburgh Hemp bore only 160 lb, when China-grass bore 250 lb., the Rheea 320 lb., and the Wild Rheea 343 lb. Mr. Henley had previously found the Kunkhoora or Rheea to bear about three times the weight of Russian Hemp. Capt. Thompson also thought it about three times as strong; and though rather too wiry, he considered it would make excellent cordage, as well as canvas. But though this is too valuable to be applied to such purposes, we have in the Wild Rheea equal strength with greater flexibility, and all that is required, as is apparent from the following abstract of the experiments made at Messrs. Huddarts's.

Experiments on Strength of Rope made from samples of Fibre of growth of India, received from Dr. Royle, at Messrs. Huddart's Rope manufactory, Limehouse, Feb. 13, 1854.

Description of Hemp.	Size of Rope.	Number of Yarns per strand.	Total number of Yarns in Rope.	Strength of Rope in pounds.	Strength of Rope per inch, circumf. squared.	Size of Rope at breaking.	Tar absorbed.	Amount of stretching.
	Inc.							
Wild Rheea, 1st expt.	4¼	44	132	19,062	·844	4¼	1-7th	1 in 16
Ditto, 2d expt.	4¼	44	132	21,025	·894	4¼	1 7th	1 in 16
Rheea Fibre.	4¼	44	132	20,488	·910	4¼	1 9th	1 in 16

So Messrs. Morgan, having made some rope for Mr. Saugester with the Rheea sent him by Major Hannay from Assam, found it to be at least 50 per cent. better than similar rope made of Russian Hemp. This is conspicuous also in the following experiments. The excellence of the fibre for lines and fine cordage is particularly observable in the fine thread called *Talli Rami* from Singapore, as likewise in the delicate nets, some of which seem fine enough for lace instead of for catching fish. The fitness of the Wild Rheea, from its strength, flexibility, and durability, is seen in the various kinds of line and cord which Dr. Royle, has had made of it in this country, as well for fishing lines, as bowstrings, clew lines for hammocks, &c., in order to show its fitness for all and every purpose to which fibrous substances require to be applied. A subsequent report was made on the strength of these fibres, when twisted into cords and rope of different sizes. "In continuation of the experiments which I made on the strength of some Indian fibres in their untwisted state, I beg leave to subjoin an account of some others that I thought it desirable to have made on some of these fibres after they had been twisted into twine, cord, and rope, of different kinds, by a regular rope-maker. This I have had done in order to obviate the objections which are made against new articles by ignorance or prejudice, or from the opposition of interested parties. "These cords and ropes having been subjected to a fresh set of experiments and compared with others made of Russian Hemp and of as nearly as possible the same size, I am happy to report that in every instance the Wild Rheea has proved stronger than Russian Hemp, and in the case of the two-inch rope the Indian fibre bore 1000 lb. more than the Russian. The cultivated Rheea, which is equally strong, will, I hope, be applied to better purposes than rope-making; but it is important that the Wild Rheea is proved by these experiments to be fit for every purpose for which strong fibre is required, either in Europe or in India." A few experiments were also made with rope made of other Indian fibres. "Plantain and Pine apple fibres, though less strong, are capable of bearing considerable weights, and might be used for many ordinary purposes. But the fibre of the Agave, commonly called American Aloe, is capable of bearing a great strain, and the plants have the peculiarity of being able to flourish in a dry soil and climate, such as that of the Deccan and of Mysore. The Dhunchee fibre of Bengal, which is hardly known in England, appears to be as strong as Russian Hemp, and is, I understand, as easily cultivated and as cheap as Jute. The results which have been obtained are as follows:—

	lb.
Wuckoo Fibre small Cord ... broke at	86
Petersburgh Hemp Cord	170

Wild Rheea Cord, same size as Russian	190
Rheea Fibre Cord, one thread larger	230
Pound line of Wild Rheea	510
Six-thread Cord of *Petersburgh Hemp* ...	505
Six-thread Ratline of Rheea, tarred ...	525
Six-thread do. of Wild Rheea, do.	530
Nine-thread do. of Wild Rheea, do. .	860
Twelve-thread do. of Wild Rheea do. ...	1120
One-inch Rope of Wild Rheea ...	1350
One-and-half-inch Rope of Wild Rheea, tarred	1900
One-and-half-inch Rope of Wild Rheea do.	1900
Two-inch Cord of *Russia Hemp*	1800
Two-inch Rope of Rheea Fibre tarred	2800
Twelve-thread Rope of Plantain made in India	864
Twelve-thread do. of Pine-apple do. ...	924
Two inch Cord of *Russian Hemp* ...	1800
Two-inch Rope of Dhunchee fibre, made in India	1850
Two-inch Rope of Agave, usually called Aloe do.	1900

For the sake of comparison we reprint the experiments made with the untwisted selvages of some of the same fibres, and of which the specimens were very carefully prepared by George Aston, and their strength tried in the office of the Military Stores.

Petersburgh Clean Hemp	broke with	160 lb.
A fibre from Travancore, called Wukka	,,	175
Yercum fibre	,,	190
Jubbulpore Hemp	,,	190
China grass, from China	,,	250
Rheea fibre or China grass, from Assam	,,	320
Wild Rheea, also from Assam	,,	343
Hemp from Kote Kangra in the Himalayas, bore without breaking.		400 lb

The other tables, in which the strength of various Indian fibres is given, as tested by different experimentalists, are to be seen, of Pine-apple fibre of Agave. &c., of Moorva, of Plantain, of different fibres, of Sunn, Jubbulpore Hemp and Dhunchee fibre, of Himalayan Hemp, and other fibres, Mudar, of Rheea and other Nettles, under the head of Fibres. The Nettles species are conspicuous for Fibrous properties, each consisting of numerous individuals widely distributed, and easily cultivated. They appear useless only because so few take the trouble, or, we should rather say, enjoy the pleasure of reading the wide-spread book of Nature. When some of the improved methods of separating fibre are successfully applied to such plants as the Rheea and Wild Rheea, the benefits to India and the world will be incalculable. For they are exceeded by none in fineness, excel all others in strength, and may be fitly compared to the trunk of the elephant, which can pick up a needle or root up a tree.—*Royle, Fib. Pl. p.* 876.

(5651) NEUROPTERA (from νεῦρον, a nerve, and πτερόν, a wing), one of the orders into which the class *Insecta* is divided.—*Eng. Cyc.*

(5652) NICANDRA PHYSALODES, Gaertn. (Atropa physalodes, Linn.) is said to be diuretic.—*O'Shaughnessy, page* 466.

(5653) NICKEL, A brilliant white metal resembling silver; ductile and malleable, and capable of receiving a high polish. It is usually procured from speise, a compound of the metal with arsenic, found associated with cobalt in Germany. Alloyed with copper, it forms argentane or german-silver; and is besides used in making mariner's compasses, and for other purposes.—*Waterston. Faulkner.*

(5654) NICOTIANA, a genus of Plants belonging to the natural order *Solanaceæ*. The species of this genus are called Tobacco. Tobacco was the name used by the Caribbees for the pipe in which they smoked it, but this word was transferred by the Spaniards to the herb itself. The genus *Nicotiana* contains about 40 species, most of them yielding tobacco for smoking, and many of them cultivated in the gardens of Europe. The name *Nicotiana* was given these plants after Jean Nicot, of Nimes, in Languedoc, who was an agent of the king of the France at Portugal, and there procured the seeds of the tobacco from a Dutchman who had procured them in Florida. Nicot sent them to France in 1560. The species of *Nicotiana* are most of them herbs, rarely under shrubs, and generally clothed with clammy hairs or down. The flowers are terminal, racemose, or panicled, and of a white, green, or purplish colour. The Calyx is 5-cleft, permanent; corolla funnel- or salver-shaped, divisions 5, plicate and spreading; stamens 5, as long as the tube of the corolla; anthers dehising lengthwise; stigma capitate; capsule 2-celled, 2-valved, valves bipartite; seeds minute, numerous. In addition to those below there are several other species of tobacco which are used for smoking in the places where they naturally grow. *N. quadrivalvis* has capsules with four valves; it grows near the Missouri River, and is there smoked by the natives. *N. multivalvis* has capsules with many valves; it is cultivated by the Indians on the Columbia River for smoking. It is a fetid plant, and the calyx, the most fetid part, is selected by the Indians for smoking. *N. nana*, a small species of tobacco, is a native among the Rocky Mountains of North America, and is smoked by the Indians. *N. repanda* is a native of Cuba, and is said to furnish the tobacco for making the small cigars known as Queen's.—*Eng. Cyc.* Tobacco leaves when properly dried have a greenish yellow colour, a strong pleasant smell, and acrid taste; taken into the stomach by persons not habituated to its effects violent vomiting, diarrhœa, and collapse are occasioned. The effects of smoking the leaf are too well known to require notice in our pages.—*O'Shaughnessy, page.* 471.

(5655) NICOTIANA. MACROPHYLLA, Orinoco Tobacco, is an herbaceous plant, with ovate-acute leaves clasping the stem; throat of corolla inflated, segments short pointed. It is a larger plant than the last, the stem rising from 5 to 7 feet high. It is a native of America, and is frequently used for smoking, under the name of Orinoco Tobacco; it is however inferior to the

last; the milder Havannah cigars are said to be made from it.—*Eng. Cyc.*

(5656) NICOTIANA PERSICA, Shiraz Tobacco, is an herbaceous plant, clothed with clammy down, with the leaves of the root oblong, those of the stem acuminate and sessile; corolla salver-shaped, with a long tube, and rather unequal segments. This plant is a native of Persia, and furnishes the famous Shiraz Tobacco. This tobacco is milder than that produced by the N. *Tabacum*, and but a small quantity is consumed in England. The English smoke more of the strongest tobacco than any nation in the world.—*Eng. Cyc.*

(5657) NICOTIANA RUSTICA. English Tobacco, has an herbaceous square stem, with petiolate ovate quite entire leaves; tube of corolla cylindrical, longer than the calyx; segments of the limbs roundish, obtuse. This plant is a native of Europe, Asia, Africa, and America. It is called English Tobacco because it was the first species that was introduced into that country for growth; it was then brought from America. It grows very well in that climate, and in some places is almost naturalised. It is known in France as Tabac Pausse, in Germany as Bauern-Tabak, and in Spain as Tabac Cimaroso. This plant grows on the coast of the Mediterranean, and thence finds its way into India, where it is highly valued. The tobaccos of Salonica and Latakkia, which are much esteemed, appear to be the produce of *N. rustica*. From the extensive range of climate and difference of situation which this plant occupies, its characters suffer considerable change; hence a number of varieties have been described. In the shops this tobacco is known as Turkish.—*Eng. Cyc.* Dr. Hooker writing of this species, says, To wind up the feast, we had pipes of excellent mild yellow Chinese tobacco called "Tseang," made from *Nicotiana rustica*, which is cultivated in East Tibet, and in West China according to M.M. Huc and Gabet. It resembles in flavour the finest Syrian tobacco, and is most agreeable when the smoke is passed through the nose. The common tobacco of India (*Nicotiana Tabacum*) is much imported into Tibet, where it is called "Tumma," (probably a corruption of the Persian "Toomback,") and is said to fetch the enormous price of 30s. per lb. at Lhassa, which is sixty times its value in India. Rice at Lhassa, when cheap, sells at 2s. for 5 lbs.; it is, as I have elsewhere said, all bought up for rations for the Chinese soldiery.—*Hooker, Him. Jour. Vol. 4, page 232.*

(5658) NICOTIANA TABACUM. Common Virginian or Sweet-Scented Tobacco, is an herbaceous plant, with acuminated oblong-lanceolate sessile leaves, lower ones decurrent; throat of corolla inflated, segments of the limb pointed. This plant is a native of the West Indies, where it first became known to the Spaniards, and of Virginia, where the English first became acquainted with its properties. Of the various species it is that which is most commonly cultivated in gardens as an ornament. It is also largely cultivated in Europe for the purpose of smoking. The other species are however in some cases preferred. Schrank has described a large number of varieties of the common tobacco, varying in the size and form of their leaves, as well as the colour and form of their corollas. This species is the one most commonly employed for making tobacco and cigars. [TOBACCO, in ARTS AND SC. DIA.]—*Eng. Cyc.* This remarkable plant we are informed by Mr. Royle, on the authority of the Persian works on Materia Medica, was introduced into India in A. H. 1014 (A. D. 1605) towards the end of the reign of Jelalooden Akbar Padshah. From India tobacco probably found its way to the Malayan Peninsula and China, though Royle quotes the authority of Pallas, Loureiro and Rumphius, who think tobacco was used in China at a period anterior to the discovery of the new world. —*Mason.*

(5659) NGAN-TSOING-SHA, a bast of Arracan.

(5660) NIGELLA (from *niger*, black, because of the colour of the seeds), a genus of Plants belonging to the natural order *Ranunculaceæ*. It has 5 coloured petal-like spreading sepals. The petals small, from 5 to 10, bilabiate, with a hollow nectariferous claw. The capsules more or less connected together, terminated by the elongated styles opening in the inside, many-seeded. The leaves are capillary, multifid, often surrounding the flowers like an involucre, and finely cut like fennel. The flowers are solitary on the tops of the stems or branches The species are erect annual smoothish herbs. The species are vulgarly known by the names Devil in a Bush and Devil in a Mist.—*Eng. Cyc.*

(5661) NIGELLA ARVENSIS, has pointed anthers; from 5 to 7 styles circinately revolute, outwardly smooth; capsules connected below the middle into an obconical fruit, which is narrowest at the base. It has a smooth stem, with diverging branches. It is a native of middle and southern Europe in corn fields, also in the north of Africa. The seeds are sometimes used instead of those of *N. sativa*, but they are not so aromatic, neither have they so pleasant a smell. Both species are employed in the adulteration of pepper. (Lindley, *Flora Medica*; Fraas, *Synopsis Plantarum Floræ Classicæ.*)—*Eng. Cyc.*

(5662) NIGELLA HISPANICA. Some of the flowers are pretty, and only require to be sown in open ground, at the commencement of the rains, the colours are chiefly pale blue and yellow.—*Riddell.*

(5663) NIGELLA SATIVA, FENNEL FLOWER. Lin.

Carin siragum, TAM.	Nulla Gilakara, TEL.
Kalunjen, DUK. & HIND.	Musavi, SANS.

See article fennel flower seed, in Catalogue 1st section 1st.—*Ainslie's Mat. Med. p. 262. N. sativa* has ovate-obtuse anthers; capsules muricated, united up to the very point into an ovate fruit, terminated by 5 erect styles; the stem erect and rather hairy; flowers naked. The seeds are angular, aromatic, subacid, and were formerly used instead of pepper: and have also been employed as carminatives. It is the Μελάνθιον of Hippocrates, 'Steril,' 675, and of Dioscorides, 3, 93; the Githex of Pliny, 20, 17.—*Eng. Cyc.* This plant is a native of the south of Europe, Egypt, Barbary, and the Caucasus, and is extensively cultivated in India. The *Seeds*, resembling coarse gunpowder, are triangular, slightly compressed, obtuse above with oblique bases, rugose, black externally, internally of a greenish white hue. The capsules are polyspermous, oblong, and pointed at the side. The seeds are of strong aromatic odour, and flavour resembling sassafras or cubebs. These properties are due to an essential oil, of which the seeds yield from 5 to 10 per cent. The nigella seeds have been long used in medicine, and are praised by Hippocrates as a tonic condiment. At present they are chiefly employed by the native Hakims as Baidas aromatic adjuncts to purgative or bitter remedies. In Bengal they are given to nurses, in the belief that they increase the secretion of milk, and facts have been laid before us which tend to corroborate that opinion. In eruptions of the skin, Dr. Ainslie informs us, the seeds reduced to powder and mixed with sesamum oil, are much used as an external application. The seed will seldom be prescribed in substance. The tincture is a useful, warm stimulant, and may be added conveniently to numerous draughts and mixtures intended for other purposes. The popular mode of giving the nigella to nurses is by mixing the powdered seed with curry, to which however it communicates a very heavy and disagreeable flavour. The price of the seed in the bazars is from one to two annas the seer,=2lbs., avoirdupois.—*O'Shaughnessy, page* 164. The tincture of it is stimulant and diaphoretic, and is recommended by native practitioners to promote the secretion of milk. Dose, half a fluid drachm to two drachms.—*Beng. Phar. page* 430.

(5664) NIGELLA SEED, KOLANJEE SEED. NIGELLA SATIVA, SMALL FENNEL FLOWER SEED. Syn.

Siah dana, PERS.	Hab Saude, EGYPT.
Kala-jira, HIND.	Gemein Nigelle. GER.
Μελάνθιον of Dioscorides.	Krishna jiraka, SANS.
Shoonez, ARAB.	Carin Sirraguin, TAM.
Mugrela, BENG.	Nulla gilakara, TEL.
Kaloodooroo, CYNG.	Kolinjee, Kalee jeera, GUZ. HIND.
Kolunjun, DUK.	

These seeds have a great resemblance to coarse gunpowder, are triangular, slightly compressed, obtuse above with oblique bases, rugose, black externally, internally of a greenish white hue. They have a strong aromatic odour, and flavour resembling sassafras or cubebs. They are used in medicine by the natives, as an aromatic adjunct to purgative or bitter remedies; and also in curries and pickles. The plant (*Nigella Sativa*), is a native of the South of Europe, Egypt, Barbary, and the Caucasus, and is extensively cultivated in India.—Produced in various parts of the Western Presidency; and exported from Bombay to London and France. —*Faulkner.*

(5665) NIGHT BLOWING CEREUS. Cereus.

(5666) NIGHTINGALE. Dr. J. D. Hooker, in this most interesting work on the Sikhim Himalaya, twice notices "the Nightingale," as having been heard by him; but at a time of the year at which no real Nightingale ever sings. Every one familiar with the true Nightingale knows that it regularly ceases to sing, somewhat abruptly, about the beginning of the month of June, and this alike whether it has young to tend in the wild state, or when confined in a cage; and captive Nightingales recommence their song, if in health and vigour, about January, and continue in full song for two months or more before their wild brethren arrive from their southern haunts. This bird never sings out of season. Accordingly we have no hesitaiton in declaring that Dr. Hooker's "Nightingale" refers to some other bird, and most probably to the Shama. "On the 4th October," he remarks, "I heard the Nightingale for the first time in the season;" and when at Pemiongchi (a former capital of Sikhim), in January, he notices that "Nightingales warble deliciously night and morning, which rather surprised us, as the minimum thermometer fell to 28°, and the ground next day was covered with hoar frost. These birds migrate hither in October and November, lingering in the Himalayan valleys till the cold of early spring drives them further south, to the plains of India, whence they return north in March and April." Among the numerous collections of Sikhim birds which we have examined, no specimen of a Nightingale has ever occurred: nor is the bird enumerated in Mr. Hodgson's lists of the species inhabiting that region.—*Bligh.*

(5667) NILGHIAU OR NYL-GHAW, PORTAX TRAGO-CAMELUS, one of the largest and most magnificent of known antelopes being upwards of 4 feet high at the shoulder; resides in the dense forests of India, is a vicious animal of very uncertain temper, and even when domesticated from both, is violent and changeable.

(5668) NIMA, a genus of Plants, belonging to the natural order *Cinarocaceæ*. It has her-

maphrodite flowers, a 5-parted permanent calyx, 5 oblong petals, 5 stamens with filaments dilated at the base; the 5 ovaries are connected together, pilose, and seated on the thick disc beneath the petals. The embryo is large, without albumen. The species are trees, with alternate imparipinnate leaves, having four parts of serrated leaflets. The flowers are disposed in panicle corymbs.—*Eng. Cyc.*

(5669) NIMA QUASSIOIDES, is a native of Nepaul, in a valley near the town called Thankot. It has elliptical oblong leaflets, which are acuminated and serrated. The corymbs are trichotomous. It is as bitter as the quassia of South America. (Don, *Dechlamdeous Plants*; Lindley, *Flora Medica.*)—*Eng. Cyc.* It grows at foot of the Himalaya mountains of which it rises to near the snow line: The wood has long been used for killing insects, and latterly recommended in fever by M. Macardieu.—*Ind. An.* 106.

(5670) NIPA FRUTICANS. This a low stemless palm that grows in the tidal waters of the Indian ocean, and bears a large head of nuts. It is a plant of no interest to the common observer, but of much to the geologist, from the nuts of a similar plant abounding in the tertiary formations at the mouth of the Thames, and having floated about there in as great profusion as here, till buried deep in the salt and mud that now forms the island of Sheppy.—*Hooker, Him. Jour. Vol.* I. *page* 1. The "Nipa" and "Sasa" of the Philippine islands possesses various useful purposes. It is the *Nipa fruticans* of botanists, and has affinities with the screwpines. The leaves are used for thatch baskets or when burnt, they yield salt: and toddy a palm wine is extracted from the spathe, convertible into syrup, sugar, vinegar, yeast and a strong spirit.—*Seeman.* The Nipah Palm from the appearance of its foliage, is generally supposed to be a Palm, though stemless, but in the nature of its flowers, it approaches the Screw Pines and is a plant of which the leaves are applied to mat making and thatching. It is a native of the Indian Archipelago, which extends northwards to the Mergui River, where it is found in perfection, but only a few specimens as far north as Moulmain. It flourishes in brackish water, along with the Mangrove, and its lower parts are inundated when the tide rises. It abounds in saccharine sap, which may be evaporated into an excellent sugar, or fermented into a kind of "Palm wine." Its leaves are those chiefly employed in the Tenasserim Provinces for covering the roofs of houses, and large quantities are sent northwards from Mergui for this purpose. They are also made into mats, and no doubt abound in fibre, though this is not separated for economic purposes.—*Royle Ill. Plants, p.* 35. The nipa is very extensively cultivated in the province of Tavoy. From incisions in the stem of the fruit, toddy is extracted, which has very much the flavour of mead, and this extract when boiled down becomes sugar. In Burmah, where the palmyra abounds, an extract from that tree is made to supply its place.—*Mason.* Writing of this plant Dr. Hooker says "Receding from the Megna, the water became saltish, and *Nipa fruticans* appeared, throwing up pale yellow-green tufts of feathery leaves, from a short thick creeping stem, and bearing at the base of the leaves its great head of nuts, of which millions were floating on the waters, and vegetating in the mud. Marks of tigers were very frequent." *Hooker, Him. Jour. Vol.* II. *page* 355.

(5671) NITRE. NITRAS POTASSÆ, NITRATE OF POTASH. *Nitrum. Salpetræ. Salpetre F.* Nitrate de Potase. Nitre. *G* Salpeter Salpetersaures Kali. Nitrate of Potash (K O, N = 102), Nitre, or Saltpetre, being a production of nature, must early have been known, especially as both the Indians and Chinese have long been acquainted with the making of fireworks, and the former have an easy process for making Nitric acid, in which they have been followed by Geber and other Arabian authors. The names *neter* in the Old Testament, and *nitrum* in ancient authors, were applied to Carbonate of Soda, but they were also used in a generic sense. Nitre is found effloresced on the soil in many parts of India, where there is no animal matter, and being washed out, a fresh crop is formed after a few years. The soil is sandy, with mica interspersed, which will continue to yield a supply of Potash, while the Nitric acid must be furnished by the combination of the Oxygen of the atmosphere with its Nitrogen, probably, as suggested by Liebig, by the oxidation of the Ammonia which he has proved is always present in the atmosphere. Mr. Stevenson (Prinsep's Journ. ii. p. 23) has detailed the process, and shown that the saline earth contains of salts soluble in water, Sulphate of Soda, Muriate of Soda, Nitrates of Lime and of Potash. The Nitrate of Lime is easily converted into that of Potash by lixiviating the saline soil over a filter of woodashes, which contains Carbonate of Potash (the Carbonic acid combines with the Lime, and the Nitric acid with the Potash), a Carbonate of Lime is precipitated, and the Nitrate Potash in solution is evaporated and put aside to crystallize. The salt obtained contains from 45 to 70 per cent. of pure Nitrate of Potash. It is redissolved and crystallised, but still contains impurities, which are termed so much per cent. of *refraction*. The ordinary kinds are called *rough* or *crude* Saltpetre, and the purer *East India refined*. In Europe Nitre is prepared artificially in Nitre-beds or Nitre-walls, and in ditches covered by sheds, where urine is added to different mixtures of earth with refuse vegetables, various animal substances, and calcareous matter, &c. The whole is exposed to the action

of the air. The Nitrogen, combining with the Oxygen, forms Nitrates, and the foregoing processes being adopted, similar results are obtained *Prop.* Nitrate of Potash in its purified state is colourless and semi-transparent, without odour, of a sharp and cooling, disagreeable, saline taste; crystallized usually in long, striated six-sided prisms, terminated at each extremity with dihedral summits, or in two or six converging planes, sometimes in a dodecahedron formed of two six-sided pyramids joined base to base. The crystals are anhydrous and unalterable in the air. Sp. Gr. 1.62. Soluble in 4 parts of water at 60° producing cold, and in an equal weight of boiling water. Insoluble in Alcohol, and sparingly so in diluted Alcohol. Heated to about 660°, it melts into a transparent fluid; in cooling, it forms a white semi transparent mass, which used to be called *Sal Prunellæ* when run into small balls. By a high degree of heat, Nitre is decomposed, Oxygen gas being first given off, and afterwards mixed with Nitrogen, while Hyponitrite of Potash is left behind. Water is apt to be lodged between the plates of the crystals, particularly when these are large; hence in gunpowder manufactories, small crystals, if equally pure, are preferred. With inflammable substances the decomposition of Nitre, when heated, is rapid, light and heat being disengaged, constituting what is called the deflagration of Nitre. This takes place also with some of the compound acids, into which Carbon enters as a constituent. Nitre being required of the best quality for the manufacture of gunpowder, that of commerce is usually sufficiently pure for medical purposes. But it sometimes requires purification to the extent of a single solution, and re-crystallization, as in the D. formula.—*Royle.*

(5672) NITRAS POTASSÆ PURIFICATUM, D. PURIFIED NITRE. *Prep.* Take *Nitr. Potash* one part, *boiling water* two parts, dissolve, remove the scum, filter, set aside for crystals to form. *Tests.* The presence of Nitric acid and of Potash may be detected by their respective tests. Nitre should be entirely soluble in distilled water. The solution should not be affected by Chloride of Barum (no Sulphates), nor by Nitrate of Silver (no Chlorides). Calcareous salts which occur only in rough Nitre, may be detected by the Oxalate of Ammonia, throwing down a white precipitate of Oxalate of Lime. Sulphate of Potash is now seldom found in the best Nitre, and only a small proportion of Chloride of Potassium or of Sodium.—*Royle.*

(5673) NITRATE OF SODA, CUBIC NITRE.

Nitrate de Soud, FR. | Wurfelsalpetre, GER.

Consists of nitric acid and soda. It is similar in its properties to saltpetre, differing chiefly in being more pungent in taste, more soluble in cold water, more inclined to attract moisture from the atmosphere, and in crystallizing in a rhomboid form. It is highly esteemed as a manure for pastures, and for all other sorts of agricultural produce, except that grown in heavy wet soils. It is also applied to many of the purposes for which saltpetre is used, though being more deliquescent than that salt, it is not adapted for the manufacture of gunpowder. This salt is found in immense quantities in deposits in South America, particularly in the districts of Atacama and Tarapaca in Peru.—*Waterton. Faulkner.*

(5674) NITRIC ACID, AQUA FORTIS. Acidum Nitricum, L. D. Acidum Nitricum purum, E. Nitric Acid, *Aqua Fortis. Spiritus Nitri Glauberi.*

Acidum Nitricum, Aqua fortis, LAT.
Pottle Ooppoo travagum, TAM.

Nitric Acid (N or NO_5=54) is a compound of Nitrogen acidified by Oxygen. It was known to Geber, and probably also to the Hindoos. Cavendish first clearly ascertained its composition by forming the acid by passing electric sparks through atmospheric air over a solution of Potash. Phil. Trans. vol. 75, p. 572, and vol. 78, p. 261. (1785.) It may frequently be detected in the atmosphere after thunder-storms, in consequence of the Oxygen and Nitrogen combining together with the aid of electricity. In combination with Potash, Soda, and Lime or Ammonia, it is found, effloresced on the soil in some countries; also in some minerals; likewise in some vegetables, as in the officinal Pareira root, in the state of Nitrate of Potash. *Prop.* Nitric is unknown anhydrous, being always seen as a liquid in combination with water. When pure, it is colourless, transparent, of a very sour corrosive taste, destroying vegetable and animal matter. It tinges the skin yellow, and causes it to peel off; gives acid properties to a large quantity of water, vividly reddening Litmus and vegetable blues. It has a strong, almost suffocating odour, fumes in the air, from condensing its moisture; fumes still more if Ammonia be present. Its affinity for water is great, absorbing it from the air, and having its Sp. Gr. and strength diminished; when mixed with it, heat is evolved. Its strength necessarily depends on the quantity of water mixed with it; the density of the L. P. acid is 1·5082 to 1·504; Mr. Phillips considers this to be the strongest procurable; but it has been brought, by distilling with a gentle heat, by Kirwan to 1·55, and by Proust to 1·62. The E. P. also employs the Nitric acid of commerce, commonly called Aqua Fortis, of Sp. Gr. 1380 to 1500. Dr. Christison considers 1500 as the densest acid which can be obtained free of Nitrous Acid, but, im-

pregnated with this, it may be got so heavy as 1540 and upwards. The purest Nitric Acid, if long exposed to light, becomes yellowish from decomposition, Oxygen being given out, and Nitrous Acid formed. This may be got rid of by the action of heat, as it escapes in the form of Nitrous acid fumes, leaving the Nitric nearly colourless. Nitric Acid, of Sp. Gr. 1·50 will freeze at −40° and will boil at 247°, but these points vary of course with the density; if the heat be continued, the acid volatilizes, and at a red heat is decomposed. At the density of 1.5 it consists of 1 Eq. of Nitric and 1½ Eq. of Water, or 54 + 13·5 = 67·5, and it then contains about 80 per cent. of acid. Many vegetable substances, as Charcoal, Sugar, Alcohol, deprive Nitric Acid of its Oxygen, also Phosphorus, and hence it is one of the most powerful oxidizing agents. The Metals do not in general decompose it when concentrated, but if diluted with water, this becomes decomposed as well as the acid, both yielding Oxygen to oxidize the Metal; the oxide is insoluble, or, being acted on by some of the undecomposed acid, a Nitrate is formed. The other part of the decomposed acid escapes in the form of Nitric oxide gas, which, uniting with Oxygen of the atmosphere, ruddy fumes of Nitrous acid gas are observed. If Copper filings be used, then the solution will be of a greenish-blue colour. If Hydrochloric Acid be mixed with the Nitric, both become decomposed, and the mixture, called Nitro-Muriatic acid or *Aqua Regia*, is capable of dissolving gold. The presence of Nitric Acid may be ascertained by the bright red colour produced when it touches Morphia or Brucia; saturated with Carb. of Potash, it forms Nitrate of Potash, which deflagrates. *Prep.* Nitric Acid may be formed by passing electric sparks through a mixture of 1 part of Nitrogen and 5 of Oxygen. The L. and E. P. direct *Nitrate of Potash* and *Sulphuric Acid* in equal quantities by weight to be mixed together in a glass retort, and the resulting Nitric Acid to be distilled in a sand-bath (or by a naked gas flame, E). The D. P. employs 100 parts of salt to 97 of common Sulphuric Acid. To obtain a pure acid, the E. P. directs the Nitrate of Potash to be purified by two or three crystallizations, till Nitrate of Silver does not act on its solution in distilled water. When manufacturers make Nitric Acid they employ only half the quantity of Sulphuric Acid and use Nitrate of Soda instead of Nitrate of Potash, because it is cheaper. The acid obtained is of a brownish colour, fumes, and is called Nitric acid of Commerce.—*Royle.* When pure, it is colourless, but as met with in commerce, it is yellowish, owing to its containing nitrous acid in solution; besides which it is often highly diluted, and mixed with sulphuric and muriatic acids. It is exceedingly corrosive, and its taste is sour and acid. Nitric acid is employed in a great variety of chemical processes; in metallurgy and assaying, for etching on iron and copper, in dyeing and in medicine.—*Faulkner.*

(5675) NITRO-MURIATIC ACID, ACIDUM NITROMURIATICUM, D. Acidum Nitrohydrochloricum. Aqua Regia.

Eau regale, Fr. | Konigswasser, Ger.

This acid is made by mixing Nitric Acid with Muriatic, and has probably been known since the discovery of these acids. The Arabs must have been acquainted with it, as they had a solvent for Gold. *Prop.* Nitrohydrochloric Acid is of a golden yellow colour with the suffocating odour of Chlorine, and the irritant corrosive properties of the strong acids. *Prep.* Mix gradually in a cooled vessel, and where the fumes can easily escape. *Nitric Acid* 1 part, *Muriatic Acid* 2 parts (both by measure). Keep the mixture in a well-closed bottle in a cool, dark place. The resulting acid is not a mere mixture of the two acids, for both become decomposed. It is distinguished by the property of disolving gold.—*Royle.*

(5676) NIZAM-OOD-DEEN AOLEEA, is a spot near Delhi where visitors used to witness some excellent feats performed by a number of swimmers, who jump into a large reservoir from a dome about fifty or sixty feet above the surface of the water.—*Tour in India by French. p.* 11.

(5677) NOLANA (so named by Linnæus, from 'nola,' a little bell, on account of the bell-shaped form of the corolla), a genus of Plants belonging to the natural order *Nolanaceæ*. It has a 5-cleft calyx; a campanulate 5-lobed 5-plicate corolla; 5 stamens adhering to the tube of the corolla, nearly equal; the anthers are 2-celled, dehiscing lengthwise. The seeds are roundish, with a membranous testa, and fleshy copious albumen. The species are herbs; natives of Peru and Chili; usually annual. Leaves alternate, quite entire. The flowers are solitary, peduncular, and of a showy blue colour. The species of *Nolana* are only valuable as ornamental plants, they are showy when in blossom, and are much like some of the trailing species of *Convolvulus*. The seeds should be sown in a gentle hot-bed in the spring, and the plants when of sufficient size, or about the middle of May, should be finally transplanted to the open ground, where they will flower and ripen seed; or the seeds may be sown at once in the open border in a warm sheltered situation.—*Eng. Cyc.*

5678) NOLANA GRANDIFLORA. Trailing annual plants with white, yellow and blue flowers, easily raised from seed, in any garden soil.—*Riddell.*

(5679) NOLE-COLE, must be sown exactly in the same manner as that recommended for cabbage, broccoli, &c. It comes in early, and remains in season until April. If watered during the hot weather and taken care of, it will, when

the rains commence, throw out sprouts, and form other knole-cole on the old stalk, which may either be used, or slipped off and planted: they will not be so fine as those raised from seed, yet are fit for use.—*Jaffrey.*

(5680) NONEA ROSEA. BORAGINEÆ. These are plants of no great beauty and may be raised in common grden soil.—*Riddell.*

(5681) NOOCHIE OIL, VITEX NEGUNDO.

(5682) NOONA BARK: MORINDA UMBELLATA. The *Noona Dye* is famous in Tanjore and the plant is grown in large quantities, the colour red but not so bright as that extracted from the Imboora, which is exported to Madura and with it the famous Madura turbands are dyed.—*M. C. C.*

(5683) NORFOLK ISLAND PINE. Araucaria excelsa, grows also in New Caledonia, Botany Island, Isle of Pines; a majestic tree growing to the height of from 60 to 228 feet, with a circumference of 30 feet. Its wood is useful for carpenters in-door-work but is too heavy for naval purposes as spars.

(5684) NUCIFRAGA, a genus of Birds known by the name of Nutcracker. One species is a native of Britain. This genus is generally considered to comprehend only two known species: *N. Caryocatactes* and *N. hemispila*, which bears a considerable resemblance to it, though it is clearly a distinct species, described and figured in Mr. Gould's 'Century of Birds from the Himalayan Mountains.' Prince C. L. Bonaparte and Mr. Audubon, include the *Corvus Columbianus* of Wilson in the genus *Nucifraga*.—*Eng. Cyc.*

(5685) NUGAR-MOTHA, Cyperus pertenuis. Very common at Ajmeer: the root has a pleasant smell: used in hair mesalihs: also considered astringent and to check diarrhœa: one tola is given.—*Gen. Med. Top. p.* 147.

(5686) NUL OR NAR. Native name of a Bengal grass of which the mats known as "Durma," are made.

(5687) NUMMULITE.

Shudnaj udsee, ARAB.

Officinal with the natives. They are lentil-shaped greyish pebbles, of various sizes, consisting of carbonate of lime and iron (with a nucleus of calcareous crystals, Royle). The Hakims administer them in eye-diseases, and ulcers.—*Honigberger.*

(5688) NURTIUNG IN THE JYNTEA HILLS. The Nurtiung Stonehenge is no doubt in part religious, as the grove suggests, and also designed for cremation, the bodies being burnt on the altars. In the Khasia these upright stones are generally raised simply as memorials of great events, or of men whose ashes are not necessarily though frequently, buried or deposited in hollow stone sarcophagi near them, and sometimes in an urn placed inside a sarcophagus, or under horizontal slabs.—*Hooker Him. Jour. Vol.* II. *page* 320. The usual arrangement is a row of five, seven, or more erect oblong blocks with round heads (the highest being placed in the middle), on which are often wooden discs and cones: more rarely pyramids are built. Broad slabs for seats are also common by the wayside. Mr. Yule, who first drew attention to these monuments, mentions one thirty-two feet by fifteen, and two in thickness; and states that the sarcophagi (which, however, are rare) formed of four slabs, resemble a drawing in Bell's Circassia and descriptions in Irby and Mangles' Travels in Syria. He adds that many villages derive their names from these stones, "mau" signifying "stone:" thus "Mausmai" is "the stone of oath," because, as his native informant said, "there was war between Churra and Mausmai, and when they made peace, they swore to it, and placed a stone as a witness;" forcibly recalling the stone Jacob set up for a pillar, and other passages in the old Testament. "Maulow" is "the stone of salt," eating salt from a sword's point being the Khasia form of oath; "Matflong" is "the grassy stone," &c. Returning from this grove, we crossed a stream by a single squared block, twenty-eight feet long, five broad, and two thick, of gray syenitic granite with large crystals of felspar.—*Hooker Him. Jour. Vol.* II. *page* 320. Notes on the Khasia mountains and people; by Lieutenant H. Yule, Bengal Engineers. Analogous combinations occur in the south of England and in Brittany, &c., where similar structures are found. Thus *maen, man,* or *men* is the so-called Druidical name for a stone, whence *Pen-maen-mawr,* for "the hill of the big stone, Maen-hayr, for the standing stones of Brittany and Dalmen, the table stone of a cromlech."—*Hooker Him. Jour. Vol.* II. *p.* 321.

(5689) NUTMEGS.

Jowzaltelb, ARAB.	Jaiphul, GUZ. HIND.

Faulkner.

The importance of this spice, requires that the opinions of various writers should be recorded. Dr. Hassall says there are three species of Myristica, which furnish nutmegs. That which yields the best description, Myristica fragrans, forms a tree from twenty to twenty-five feet high, somewhat similar in appearance to a pear tree. The fruit is smooth externally pear shaped, and about the size of an ordinary peach. It consists, first of an outer

fleshy covering, called the pericarp, which when mature separates into nearly equal longitudinal parts, or valves, secondly, of the aril, or mace, which, when recent, is of a bright scarlet colour; and thirdly, of the seed proper, or nutmeg. This is enclosed in a shell, which is made up of two coats, the outer is hard and smooth, the inner, thin, closely invests the seed sending off prolongations which enter the substance of the seed and which being coloured, impart the marbled or mottled appearance characteristic of nutmeg. Nutmegs are cultivated in the Molucca Islands, and espcially in those called the Banda, or Nutmeg Islands. It is also grown in Java, Sumatra, Penang, Singapore, Southern India, Bengal, Bourbon, Island of Madagascar, and certain of the West India Islands. There are two kinds of nutmegs met with in commerce. The first, called the true, round, cultivated, or female nutmeg, is the product of Myristica fragrans. These nutmegs are characterised by their full and rounded form and delicate and aromatic flavour; they are occasionally imported in the shell. There is also a small variety, not larger than a pea, which has been described under the name of the royal nutmeg. Three varieties of true nutmeg are distinguished by dealers, which are thus described in Pereira's Materia Medica:"—

1. "*Penang nutmegs.*—These are unlimed or brown nutmegs, and fetch the highest price. They are sometimes limed in Britain for exportation, as on the Continent the limed sort is preferred. According to Newbold, the average amount annually raised at Penang is 400 piculs (of 133⅓ lbs. each).

2. "*Dutch or Batavian nutmegs.*—These are limed nutmegs. In London they scarcely fetch so high a price as the Penang Sort.

3. "*Singapore nutmegs.*—These are a rougher, unlimed, narrow sort, of somewhat less value than the Dutch kind. According to Mr. Oxley, 4,085,361 nutmegs were produced at Singapore in 1848, or about 252 piculs (of 133⅓ lbs. each); but the greater number of the trees had not come into full bearing, and it was estimated that the amount would in 1849, be 500 piculs. The second kind of nutmeg is called the false, long, wild, or male nutmeg, and is the produce chiefly of Myristica fatua; but a kind of nutmeg which is also called wild, is obtained from Myristica Malabarica. The seeds of Myristica fatua, are about half as long again as the true or round nutmeg; they are paler, and less aromatic. The wild nutmeg obtained from the Myristica Malabarica, has scarcely any flavour or odour, and, according to Rheede is of the size and figure of a date "The Turkish and Jewish merchants," writes Rheede "mix these nutmegs with the true long ones, and the mace with good mace, selling them together. They also extract, from these inferior articles an oil, with which they adulterate that of a more genuine quality." In the Banda Islands, three crops or harvests of nutmegs are obtained in the year, the principal gathering is in July or August; the second in November; and the third in March or April. The fruit is gathered by means of a barb attached to a long stick; the mace is separated from the nut and separately cured. On account of their liability to the attacks of an insect known as the nutmeg insect, considerable care is required in drying them. They should be dried in their shells, as they are then secure from the insect. They are placed on hurdles, and smoke-dried over a slow wood fire for about two months. In the Banda Islands, they are first dried in the sun for a few days. When the operation of drying is complete, the nuts rattle in their shells; these are cracked with mallets, and the damaged, shrivelled, or worm-eaten nuts removed. To prevent the attacks of the insect, the nuts are frequently limed. For the English market, however, the brown or unlimed nutmegs are prepared. The Dutch lime them by dipping them into a thick mixture of lime and water, but this process is considered to injure their flavour. Others lime them by rubbing them with recently-prepared, well-sifted lime. This process is sometimes practised in London. The following account is extracted from McCulloch's Dictionary of Commerce, *of the Quantities of Nutmegs entered for Home Consumption in the United Kingdom, in* 1840, 1841, 1842, *and the amount of Duty received thereon.*

Quantities.		Duties.	
	lbs.	£.	s.
1840.....	118,664	1840... 15,041	9
1841.....	113,441	1841... 14,851	10
1842.....	170,064	1842... 22,018	12

In 1842, the duties were fixed at 3*s.* 6d. per lb. on those from a foreign, and at 2*s.* 6*d.* per lb. on those from a British possession. The duty on wild nutmegs in the shell was then also fixed at 3*d*, without regard to origin. The duty now is 1*s.* per lb; on wild nutmegs in the shell, 3*d.* per lb., not in the shell, 5*d.* per lb. Wholesale price, 1*s.* 9*d.* to 4*s.* Were entered for home consumption in 1852, 239, 200 lbs.; in 1853, 208, 198 lbs. It appears from Dr. Hassall's inquiries, 1st. That nutmegs, as they reach the consumer are not in general deprived of their essential oil; a result contrary to the opinion commonly entertained on this point. 2nd. That, as met with in the English markets, they are seldom limed.—*Food and its adulteration, p.* 408. Crawfurd says the species of the genus Myristica are numerous and wide-spread, for some are found in all the islands of the Archipelago, in several parts of Hindustan, in the Hindu-Chinese countries, in the Philippines, in Australia, and in tropical America. As a spice, however, the moschata or aromatic, is the only one of which the nut or mace is of any value, and of this the geographical

limits are comparatively narrow, being comprehended between the 126th and 135th degrees of east longitude, and the 3rd degree of north, and the 7th of south latitude. It is, or has been, found wild in the proper Moluccas, in Gilolo, Ceram, Amboyna, Boeroe, Dammma, the North and south sides of the western peninsula of New Guinea, and in all its adjacent islands. It certainly does not exist in its wild state in any of the islands west of these, nor in any of the Philippines. Wherever the soil and climate are suitable for its growth the aromatic nutmeg is raised with great facility. It is even transported to remote parts, and the seed is disseminated by birds that feed on the mace dropping the nut. These birds consist of two species of pigeon, Colomba perspicillata and ænea, which prey on the nutmeg as our own wood-pigeons on the acorn.

In its native country the nutmeg tree comes into full bearing in its ninth year, and lives to seventy-five. In shape and size, the ripe fruit resembles a peach, or rather a nectarine. When ripe, the fleshy outer substance bursts, the nutmeg in its black shining shell is seen through the interstices of its reticulated crimson envelope, the mace, which last amounts to about one-fifth part of the weight of the whole dried fruit. These two articles, the nut and mace, constitute the spices which for so many ages have been in request among the nations of Europe and Asia, although never used as a condiment by the inhabitants of the countries that produce it. The English, after the unsuccessful efforts of two centuries, succeeded at length in participating in the nutmeg trade, in consequence of having occupied the Spice Islands in 1796. In 1798 the nutmeg was introduced into Bencoolen and Penang, and in 1819 into Singapore, and at these places it is now largely cultivated, but certainly under the disadvantage of growing as a not readily acclimated exotic. In countries native and congenial to it, the nutmeg is reared with great ease, requiring little care beyond shelter from the sun and weeding.—*Crawfurd Dict. p.* 305. At the Madras Exhibition of 1855, fine samples of nutmegs were sent by General Cullen from his gardens, Velley Malay near Oodlagherry south of Travancore, 1800 feet above the sea. Two sorts of nutmegs were exhibited by C. S. Vernede Esq. Commercial Agent to the Cochin government; first sort, averaging 70 to the pound, and the second sort, 100 to the pound; the former are particularly fine. In some instances the nutmegs had been coated with chunam to preserve them. Wild or spurious nutmeg, was also forwarded from the Bababoodeen Hills, Mysore, and from Canara; it is much used as a substitute for the true spice, but is almost wholly devoid of aroma and of no interest.—*M. E.* The nutmeg tree has been found growing wild in Assam, lat. 27° 30" and probably it would succeed in higher latitudes in America.—*Bonynge, America, p.* 155. Both Nutmegs and Mace, according to Tomlinson, are the produce of the same tree (*Myristica moschata*), a native of the Moluccas Islands, but cultivated in Sumatra, Java, and elsewhere in the East. It is likewise cultivated in several of the West India Islands, but with less success. The fruit of the nutmeg-tree is as large as that of our peach; but when ripe the fleshy part bursts asunder into halves, showing the stone (as we should call it in the peach) which contains within it the valuable kernel or nutmeg. But this stone is itself covered with a membranous kind of network, of a bright red colour, which is the mace: in drying, this afterwards becomes orange yellow. The appearance of the rich brown shell of the nutmeg covered with the red fibres of the mace is very beautiful in the fresh fruit. These fibres being removed, the shells are dried in the sun or by a moderate fire until they split, revealing the aromatic kernel or nutmeg. Nutmeg plantations are formed in alluvial ground, or in virgin forest land in level situations. Declivities are unfavourable on account of the slight hold these trees take on the soil, and the consequent danger of their being uprooted during the heavy rains which occur in tropical countries. Their culture in Bencoolen, which represents the ordinary mode of treatment has been minutely described by Dr. Lumsdaine, in a paper originally communicated to the Agricultural Society of Sumatra, in 1820, and recently republished in Silliman's American Journal of Science and Arts. From this account we learn that in originating a nutmeg plantation it is necessary to select ripe and sound nuts, and set them at the distance of a foot apart in a rich soil, covering them lightly with mould. They must then be watered every other day, weeded occasionally, and shielded from a scorching sun. In from one to two months the young seedlings may be expected to appear; and when about 4 feet high, the healthiest and most luxuriant are to be removed at the commencement of the rainy season to the plantation previously cleared and prepared for that purpose, and set at the distance of 30 feet from each other, care being taken to protect them from the heat and from violent winds. The plants are set in rows, and between these the plough is employed to clear the intermediate spaces of weeds and grasses, which in warm climates spring up in great luxuriance and choke the soil. The plants continue to require watering every other day in sultry weather; and in nearly all cases the soil requires to be enriched with annual supplies of manure, which are laid on during the rains, and which are made more stimulating as the tree approaches in age. After the fifth year the trees no longer require to be shielded from the sun; in the seventh year they begin to bear fruit; and from that time to

the fifteenth year they generally increase in fruitfulness, being then in their highest perfection. During the progressive growth of the plantation, the beds of the trees are regularly weeded, and the roots kept covered with the mould, for these have a constant tendency to seek the surface: the growth of lateral branches is alone encouraged, and all suckers or dead and unproductive branches are removed by the pruning-knife, so as to thin the trees considerably, and admit of the descent of the night-dews, which contribute much to their well-being, especially during dry and sultry weather. The conclusion of the principal harvest is the time chosen for these prunings. As the trees advance in age, the coarser vegetation and creepers are alone removed from the intervals between the trees, and the more harmless grasses are allowed to remain, giving the plantation a park-like appearance. The use of the plough is then discontinued. Nutmeg-trees are of two kinds in the same plantation, flower-bearing, and fruit-bearing. The productive plants are in the proportion of about two-thirds to the whole plantation. It is impossible to discover the difference in the sexes of the plants until the period of flowering. Between the appearance of the blossom and the ripening of the fruit, a period of 7 months generally elapses; but when once a tree has begun bearing, it continues to produce fruit all the year round, but more plentifully in some months than in others. The months of September, October, November and December, are the period of the great harvest; those of April, May, and June of the smaller harvest. In the Moluccas these trees continue prolific for 70 or 80 years; and the annual produce, taking one tree with another, amounts to about five pounds of nutmegs and a pound and a quarter of mace of each tree. When the fruit is ripe, which is indicated by the bursting open of the fleshy portion, and the appearance of the kernel, it is gathered in by means of long hooked sticks. The first step, after removing the outer integument, is cautiously to strip off the mace, and flatten it by hand in single layers placed on mats and dried for 3 or 4 days in the sun. In damp and rainy weather the heat of a charcoal fire is employed, but with care that no smoke or heat blacken the surface of the mace. In drying, the red tint of the mace changes to orange, its substance becomes horny and brittle, and its strongly aromatic odour and taste are preserved. When well cured, it is made up in tight packages in a dry situation; but is exposed to the sun about once a fortnight to preserve its dryness, and thus to keep it from insects which attack it if it becomes damp. The nuts being liberated from their mucy envelope, are conveyed to the drying house and placed on a raised stage or framework, which admits the heat from a smouldering fire beneath it, to pass freely among them. The heat is kept below 140° Fahr., because too great a heat dries up the kernels, while too long continued heat produces fermentation, which increases their volume so greatly as to fill up the whole cavity of the shell, and thus prevent them from rattling, which is the criterion of due preparation. The drying-house is a brick building of suitable size, and the stage is placed at an elevation of 10 feet having 3 divisions in it for the produce of different months. The nuts are turned every second or third day, that they may all partake equally of the heat, and such as have undergone the smoking process for the period of two complete months, and rattle freely in the shell, are cracked with wooden mallets, and the worm-eaten and shrivelled ones thrown out. The sound nutmegs are rubbed over with recently prepared well sifted dry lime, and packed tightly in chests, the seams of which have been made impervious to air and water. Another and a more common method is to dip them in a mixture of salt-water and lime, and then to spread them out for 4 or 5 days in the shade to dry. But the quantity of moisture imbibed during this process, appears to increase the liability to early decay and to the attacks of insects. The surest way of preserving the kernel would be to export it in the shell; this is done in sending nutmegs to China; but it does not answer in Europe, on account of the heavy allowance for shells, which is one third of the weight. The general qualities of the nutmeg and mace are the same: their agreeable aromatic odour and pungent taste are well known, the peculiar flavour of the mace, however, being quite distinct from that of the nut. They contain, according to Bonastre, fat oil 31-6 per cent., volatile oil 6-0, starch 24, gum 1·2, free acid 0·8, ligniue 54. Not more than 4-5 per cent. of volatile oil is usually obtained in the distillations at Apothecaries' Hall. The fixed oil, called *nutmeg butter* or *expressed oil of nutmeg*, is prepared in Holland: the nutmegs are beaten into a paste, which is enclosed in a bag, steamed and pressed between hot plates. It is imported in oblong cakes, wrapped in flag-leaves or leaves of the banana, and weighing about three quarters of a pound. It is of an orange or reddish brown colour, and of a fragrant odour. It is liable to much adulteration, and so also is the volatile oil, with which turpentine is frequently mixed. The article called *expressed oil of mace* is obtained from the nutmeg, and should bear its name. Nutmeg butter, according to Playfair, consists of three fatty substances, two of which are soluble in alcohol, and the third almost insoluble in that fluid; the third substance has been termed *Myristine* and from this *myristic acid* is prepared. Nutmegs are sometimes passed off as "fresh," after the volatile oil has been abstracted from them. Such nutmegs are very

light, and when pierced with a hot needle, do not give an oily coating to it. The best nutmegs are small, but heavy, weighing on an average 90 grains each. There is a large and inferior kind of nutmeg imported, longer and heavier than the above, weighing as much as 110 grains. This is the produce of another variety, and sometimes of a distinct species of nutmeg, and is said to be more liable to produce narcotic symptoms than the true nutmeg. Nutmegs and mace are decidedly stimulant, and in small quantities wholesome. When used in abundance they produce, by increasing the circulation, narcotic effects.—*Tomlinson.* According to *Mr. Simmonds*, the Nutmeg tree *Myristica moschata, M. officinalis*, or *aromatica*, is of a larger growth than the clove, attaining a height of thirty feet, and has its leaves broader in proportion to their length; the upper surface of these is of a bright green, the under of a greyish color. It is a dioecious plant, having male or barren pale yellow flowers upon one tree, and female or fertile flowers upon another. The fruit is drupaceous, and opens by two valves when ripe, displaying the beautiful reticulated scarlet arillus, which constitutes mace. Within this is a hard, dark brown, and glossy shell, covering the kernel, which is the nutmeg of the shops. The kernels of *M. tomentosa* are also used as aromatics, under the name of wild or male nutmegs. Lindley describes two other species, *M. fatua*, a native of Surinam, with greenish white flowers, and *M. sebifera* or *Virola sebifera*, a native of Guiana, with yellowish green flowers. By expression, nutmegs are made to yield a concrete oil, called *Adeps Myristicæ*, or sometimes erroneously oil of mace. A volatile oil is also procured by distillation. Nutmegs and mace are used medicinally as aromatic stimulants and condiments. In large doses they have narcotic effects. The fleshy part of the fruit is used as a preserve. Dr. Oxley has given such an admirable account of the nutmeg and its cultivation, as the result of 20 years experience in Singapore, that Simmonds draws largely from his valuable paper, which is contained in the second volume of "The Journal of the Indian Archipelago," page 641. The nutmeg tree, like many of its class, has a strong tendency to become monoecious, and planters in general are well pleased at this habit, thinking they secure a double advantage by having the male and female flowers on the same plant. This is, however, delusive, and being against the order of nature, the produce of such trees is invariably inferior, showing itself in the production of double nuts and other deformities. It is best, therefore, to have only female trees, with a due proportion of males. The female flowers, which are merely composed of a tripid calyx and no corolla, when produced by a tree in full vigor are perfectly urceolate, slightly tinged with green at the base, and well filled by the ovary, whereas the female flowers of weakly trees are entirely yellow, imperfectly urceolate, and approach more to the staminiferous flowers of the male. The shape of the fruit varies considerably, being spherical, oblong, and egg-shaped, but the nearer they approach sphericity of figure, the more highly are they prized. There is also a great variety in the foliage of different trees, from elliptic, oblong and ovate, to almost purely lanceolate-shaped leaves. This difference seems to indicate in some measure the character of the produce; trees with large oblong leaves appearing to have the largest and most spherical fruit, and those with small lanceolate leaves being in general more prolific bearers, but of inferior quality. Whilst its congener the clove has been spread over Asia, Africa, and the West Indies, the nutmeg refuses to flourish out of the Malayan Archipelago, except as an exotic, all attempts to introduce it largely into other tropical countries having decidedly failed. The island of Ternate, which is in about the same latitude as Singapore, is said to have been the spot where it was truly indigenous, but no doubt the tree is to be found on most of the Moluccas. At present the place of its origin is unproductive of the spice, having been robbed of its rich heritage by the policy of the Dutch, who at an early period removed the plantations to the Banda isles for better surveillance, where they still remain and flourish. But although care was formerly taken to extirpate the tree on the Moluccas, the mace-feeding pigions have frustrated the machinations of man, and spread it widely through the Archipelago of islands extending from the Moluccas to New Guinea. Its circle of growth extends westward as far as Pinang, or Prince of Wales Island, where, although an exotic, it has been cultivated as a mercantile speculation with success for many years. Westward of Pinang there are no plantations, looking at the subject in a mercantile point of view. The tree is to be found, indeed, in Ceylon, and the West Coast of India, but to grow it as a speculation out of its indigenous limits, is as likely to prove successful as the cultivation of apples and pears in Bengal. In the Banda Isles, where the tree may be considered as indigenous, no further attention is paid to its cultivation than setting out the plants in parks, under the shade of large forest trees, with long horizontal branches, called "Canari" by the natives. There it attains a height of 50 feet and upwards, whereas from 20 to 30 feet may be taken as a fair average of the trees in the Straits' Settlements, but notwithstanding our pigmy proportions (adds Dr. Oxley), it does not appear, from all I could ever learn, that we are relatively behind the Banda trees, either in quantity or quality of produce, and I am strongly impressed with the idea that the island of Singapore can compete with the Banda group on perfectly even terms. Our cli-

mate is quite unexceptionable for the growth of the nutmeg, being neither exposed to droughts or high winds; and although we may lose by comparison of soils, we again gain by greater facilities of sending our products to market, by the facility of obtaining abundant supplies of manure, and any amount of free and cheap labor. A nutmeg plantation, well laid out and brought up to perfection, is one of the most pleasing and agreeable properties that can be possessed. Yielding returns, more or less daily, throughout the year, there is increasing interest, besides the usual stimulus to all agriculturists of a crop time, when his produce increases to double and quadruple the ordinary routine. Trees having arrived at fifteen years growth, there is no incertitude or fear of total failure of crop, only in relative amount of produce, and this, as will be seen, is greatly in the planter's own power to command. It is against reason to suppose that a tree in flower and fruit will not expend itself if left to unaided nature: it must be supplied with suitable stimuli to make good the waste, therefore he who wants nuts must not be sparing of manure. The first requisite for the planter is choice of location. It is true that the nutmeg tree, aided by manure, will grow in almost any soil where water does not lodge, but it makes a vast difference in the degree of success, whether, the soil be originally good, or poor and improved by art. The tree does not thrive in white or sandy soils, but prefers the deep red and friable soils formed by the decomposition of granite rocks and tinged with iron, and the deeper the tinge the better. I am therefore inclined to think, that iron in the soil is almost necessary for the full development of the plant. If under the before-mentioned soil there be a rubble of iron-stone at four or five feet from the surface (a very common formation in Singapore), forming a natural drainage, the planter has obtained all that he can desire in the ground, and needs only patience and perseverance to secure success. The form of the ground ought to be undulating, to permit the running off of all superfluous water, as there is no one thing more injurious to the plant than water lodging around its roots, although, in order to thrive well, it requires an atmosphere of the most humid sort, and rain almost daily. Besides the form of the ground, situation is highly desirable particularly as regards exposure. A spot selected for a nutmeg plantation cannot be too well sheltered, as high winds are most destructive to the tree, independently of the loss occasioned by the blowing off of fruit and flower. At present there is abundant choice of land in Singapore, the greater portion of the island being as yet uncultivated, and much answering to the above description. The land can be purchased from Government at the rate of from 10s. to 30s. per acre in perpetuity. I would advise the man who wishes to establish a plantation, to select the virgin forest, and of all things let him avoid deserted gambier plantations, the soil of which is completely exhausted, the Chinese taking good care never to leave a spot until they have taken all they can out of it. A cleared spot has a great attraction for the inexperienced, and it is not easy to convince a man that it is less expensive to attack the primitive forest, than to attempt to clear an old gambier plantation, overrun with lalang grass; but the cutting down and burning of large forest trees is far less expensive than the extirpation of the lalang, and as the Chinese leave all the stumps of the large trees in the ground, it is almost more difficult to remove them in this state than when you have the powerful leaver of the trunk to aid you in tearing up the roots, setting aside the paramount advantage that, in the one case you possess a fresh and fertile soil, in the other an effete and barren one. Forest land, or "jungle," as it is called in the East, can be cleared for about 25 to 30 dollars (£5 to £6) per acre, by contract, but the planter had better be careful to have every stump and root of tree removed, ere he ventures to commence planting, or the white ants, attracted by the dead wood, will crowd into the land, and having consumed the food thus prepared for them, will not be slow in attacking the young trees. Whilst the planter is thus clearing the ground, he may advantageously at the same time be establishing nurseries; for these the ground ought to be well trenched and mixed with a small quantity of thoroughly decomposed manure and burned earth, making up the earth afterwards into beds of about three feet wide, with paths between them for the convenience of weeding and cleaning the young plants. Of course if the planter can obtain really good plants, the produce of well-selected seed, it will be a great saving of time and expense to him, but unless the seed be carefully chosen, I would prefer beginning my own nurseries, and in the selection of seed would recommend the most perfectly ripe and spherical nuts. Oval long nuts are to be rejected, particularly any of a pale color at one end. The planter having selected his seed, which ought to be put in the ground within twenty-four hours after being gathered, setting it about two inches deep in the beds already prepared, and at the distance of twelve to eighteen inches apart, the whole nursary to be well shaded both on top and sides, the earth kept moist and clear of weeds, and well smoked by burning wet grass or weeds in it once a week, to drive away a very small moth-like insect that is apt to infest young plants, laying its eggs on the leaf, when they become covered with yellow spots, and perish if not attended to speedily. Washing the leaves with a decoction of the Tuba root is the best remedy I know of, but where only a few plants are affected, if the spots

be numerous, I would prefer to pluck up the plant altogether, rather than run the risk of the insect becoming more numerous, to the total destruction of the nursery. The nuts germinate in from a month to six weeks, and even later, and for many months after germination the seed is attached to the young plant, and many be removed apparently as sound as when planted, to the astonishment of the unlearned, who are not aware of the great disproportion in size between the ovule and albumen, the former of which is alone necessary to form the plant. The plant may be kept in nursery with advantage for nearly two years. Should they grow rapidly, and the interspaces become too small for them, every second plant had better be removed to a fresh nursery, and set out at a distance of a couple of feet from each other. When transplanted, either in this way or for their ultimate position in the plantation, care should be taken to remove them with a good ball of earth, secured by the skin of the plantain, which prevents the ball of earth falling to pieces. The nurseries being established, the ground cleared and ready, the next proceeding is to lay out and dig holes about 26 or 30 feet apart, and as the quincunx order has so many advantages, it is the form I would recommend for adoption. The holes should be at least six feet in diameter, and about four feet deep, and when refilled the surface soil is to be used, and not that which is taken out of the hole. Each hole should be filled up about one foot higher than the surrounding ground, to allow for the setting of the soil and the sinking of the tree. which, planted at this height, will in a few years be found below the level. Over each hole thus filled up, a shed, made of Attap leaves or other shelter, closed on two sides, east and west, and proportioned to the size of the plant, is to be erected. It is not a bad plan to leave an open space in the centre of the top of each shed, about twelve inches wide, by which the young plant can obtain the benefit of the dew and gentle rains, which more than compensates for the few rays of sun that can only fall upon it whilst that body is vertical. After the sheds have been completed, each hole should have added to it a couple of baskets of well decomposed manure, and an equal quantity of burned earth, when all is ready for the reception of the plant, which, having been set out, if the weather be dry will require watering for ten days or a fortnight after, in fact until it takes the soil. The planter having set out all his trees must not deem his labors completed, they are only commencing. To arrive thus far is simple and easy, but to patiently watch and tend the trees for ten years after, requires all the enthusiasm already mentioned. About three months after planting out, the young trees will receive great benefit if a small quantity of liquid fish manure be given them. In the first six years they ought to be trenched round three times, enlarging the circle each time, the trenches being dug close to the extremities of the roots, which generally correspond to the ends of the branches, and each new trench commencing where the old one terminated. They must of course greatly increase in size as the circle extends, requiring a proportionate quantity of manure, but the depth ought never to be less than two feet. The object of trenching is to loosen the soil and permit the roots to spread, otherwise the tree spindles instead of becoming broad and umbrageous. Manure is beyond all other considerations the most important to the welfare of the estate; it is that which gives quantity and quality of produce, and without it a plantation cannot be carried on. The want of it must limit the cultivation in the Straits' Settlements, and will arrest many a planter, who, having got his plantation to look well up to the eighth year with very little manure, thinks he can go on in the same manner. The nutmeg tree likes well all sorts of manures, but that which is best suited for it seems to be well-rotted stable and cow-yard manure, mixed with vegetable matter, and when the tree is in bearing the outer covering of the nut itself is about one of the very best things to be thrown into the dung-pit. Dead animals buried not too near the roots, also blood, fish, and oil cakes are beneficial. Guano is of no use. But although manuring is the chief element in successful cultivation, there are many other matters for the planter to attend to during the period that the trees are growing. All obnoxious grasses must be carefully kept out of the plantation, at least from between the trees, and the harmless grasses rather encouraged, as they keep the surface cool. The trunk of the tree ought to be carefully washed with soap and water once a year to keep it clear of moss; this has been ridiculed as a work of supererogation, but let those who think so omit the operation. Parasitical plants of the genus Loranthus are very apt to attach themselves to the branches, and if not removed do great injury The insect enemies of the tree are not very numerous, but it has a few, white ants among the number. They seldom attack a vigorous plant; it is upon the first symptoms of weakness or decay that they commence their operations. Their nests may be dislodged from the roots of the plant by a dose of solution of pig dung, to which they have a great aversion. There are several species of insects which lay their eggs on the leaves, and unless carefully watched and removed, they commit great havoc amongst the trees. For this purpose it is necessary to wash the leaves with a decoction of Tuba root, and syringe them by means of a bamboo with lime and water, of the consistence of whitewash; this adheres to the leaves, and will remain even after several heavy showers. Another nuisance is the nest of the large red

ant; these collect and glue the leaves together, forming a cavity for the deposition of their *larvæ*. The best mode of destroying them is to hang a portion of some animal substance, such as the entrails of a fowl, fish, &c. to the end of a pole thrust through and protruding from the branches; the ants will run along the pole and collect in immense quantities around the bait, when, by a lighted faggot, they can be burned by thousands. This repeated once or twice a day for a week or so, will soon rid the tree of the invaders. The number of men to be kept on an estate to preserve it in first-rate order after it has come into bearing, must depend of course upon the size of the plantation, but in general one man for every one hundred trees will be found sufficient, provided there be some four or five thousand trees. On a small scale the proportion must be greater. The nutmeg planter is under the necessity of keeping up nurseries throughout the whole of his operations for the replacement of bad plants and redundant males. Of the latter ten per cent. seems to be about the best proportion to keep, but I would have completely diœcious trees. No person can boast to get a plantation completely filled up and in perfect order much sooner than fifteen years. Of the first batch planted, not more than one half will turn out perfect females, for I do not take into account monœcious trees, which I have already condemned. The tree shows flower about the seventh year, but the longer it is before doing so, the better and stronger will it be. I cannot refrain from a smile when a sanguine planter informs me with exultation that he has obtained a nut from a tree only three or four years planted out; so much the worse for his chance of success, too great precocity being incompatible with strength and longevity. The best trees do not show flower before the ninth year, and one such is worth a score of the others. This will be evident when it is stated that I have seen several trees yield more than 10,000 nuts each in one year, whereas I do not believe that there is a plantation in the Straits that averages 1,000 from every tree. This very great disparity of bearing shows plainly that the cultivation of the plant is not yet throughly understood, or greater uniformity would prevail, and I think it clearly enough points out that a higher degree of cultivation would meet its reward. The tree has not been introduced into the Straits' sufficiently long to determine its longevity, but those introduced and planted in the beginning of the present century, as yet show no symptoms of decay. *The experiment of grafting the trees*, which at first view presents so many advantages, both in securing the finest quality of nut and the certainty of the sex, has still to be tried in this cultivation. Some three years ago (continues Dr. Oxley), I succeeded in grafting several plants by approach; these are not sufficiently old for me to decide whether it be desirable or not, for although the plants are looking well and growing, they as yet have thrown out their branches in a straggling irregular manner, having no leaders, and consequently they cannot extend their branches in the regular verticles necessary for the perfect formation of the tree without which they must ever be small and stunted, and consequently incapable of yielding any quantity of produce. The grafts have succeeded so far as stock and scion becoming one, and in time a perpendicular shoot from the wood may appear. If after that it should increase in size and strength, so as to form a tree of full dimensions, the advantage gained would be worth any trouble, the quality of some nuts being so far above that of others it would make a difference beyond present calculation; in short 1,000 such picked trees at the present prices would yield something equivalent to £4,000 a year, for £4 per tree would be a low estimate for such plants. If this ever does occur, it will change the aspect of cultivation altogether, and I see no good reason why it should not, except that those possessing trees of the quality alluded to, would not very willingly permit others to graft from them, so it is only the already successful planter who can try the experiment properly. An acre of land contains on an average 92 trees, and it is calculated an outlay of 300 dollars is required upon every acre to bring the tree to maturity; but as not more than one-half of the trees generally turn out females, and as many others are destroyed by accident and diseases to which this plant is very liable, it makes the cost of each tree, by the time it yields fruit, about eight dollars. The nutmeg tree begins to bear when about eight years old, but it gives no return for several years longer; and therefore to the expense of cultivation must be added the interest of the capital sunk. The plant being indigenous in the Moluccas, the expense of cultivation there is greatly less, and this consequently forms a strong ground of claim to the British planter for protective duties to their spices from the British Government. The planter having his tree arrived at the agreeable point of producing, has but slight trouble in preparing his produce for market. As the fruit is brought in by the gatherers, the mace is carefully removed, pressed together and flattened on a board, exposed to the sun for three or four days, it is then dry enough to be put by in the spice-house until required for exportation, when it is to be screwed into boxes, and becomes the mace of commerce. The average proportion of mace yielded in Singapore is one pound for every 433 nuts. The nutmeg itself requires more care in its curing, it being necessary to have it well and carefully dried ere the outer black shell be broken. For this purpose the usual practice is to subject

it for a couple of months to the smoke of slow fires kept up underneath, whilst the nuts are spread on a grating about eight or ten feet above. The model of a perfect drying-house is easily to be obtained. Care should be taken not to dry the nuts by too great a heat, as they shrivel and lose their full and marketable appearance. It is therefore desirable to keep the nuts, when first collected, for eight or ten days out of the drying-house, exposing them at first for an hour or so to the morning sun, and increasing the exposure daily until they shake in the shell. The nuts ought never to be cracked until required for exportation, or they will be attacked and destroyed by a small weasel-like insect, the larvæ of which is deposited in the ovule, and, becoming the perfect insect, eats its way out, leaving the nut bored through and through, and worthless as a marketable commodity. Liming the nuts prevents this to a certain extent, but limed nuts are not those best liked in the English market, whereas they are preferred in that condition in the United States. When the nuts are to be limed, it is simply necessary to have them well rubbed over between the hands with powdered lime. By the Dutch mode of preparation, they are steeped in a mixture of lime and water for several weeks. This no doubt will preserve them, but it must also have a prejudicial effect on the flavor of the spice. After the nuts are thoroughly dried, which requires from six weeks to two months smoking, they cannot be too soon sent to market. But it is otherwise with the mace; that commodity, when fresh, not being in esteem in the London market, seeing that they desire it of a golden color, which it only assumes after a few months, whereas, at first when fresh it is blood red, now red blades are looked upon with suspicion, and are highly injurious to the sale of the article. This is one of those peculiar prejudices of the Englishman which somewhat impugns his wisdom; but it must be attended to, as he is very ready to pay for his caprice; therefore those who provide for him have no right to complain, although they may smile. The nutmeg tree was sent from Bencoolen to Singapore, the latter end of 1819, so that thirty-four years have elapsed since its first introduction. Sir Stamford Raffles shipped to the care of the resident commandant, Major Farquhar, 100 nutmeg plants, 25 larger ditto, and 1,000 nutmeg seeds, which were committed to the charge of Mr. Brooks, a European gardener, who was specially engaged by the East India Company to look after their embryo spice plantations here. Some of these plants were set out in rather a bad soil and locality, but several of them are at present, and have been for the last ten years, fine fruitful trees. 315 of the trees in the Government garden yielded, in 1848, 190,426 nuts, or at the average of 604 for each tree; but of these not over 50 were of the old stock, most having been planted since 1836; so that a planter may safely calculate on having a better average than is here set forth, provided he attends to his cultivation, and his trees are brought up to the age of fifteen years. If a plantation be attended to from the commencement after the manner I have endeavoured to explain, and the trees be in a good locality, the planter will undoubtedly obtain an average of 10 lbs. of spice from each tree from the fifteenth year; this, at an average price of 2s. 6d. per lb., is 25s. per annum. He can have about seventy such trees in an acre, so that there is scarcely any better or more remunerative cultivation when once established. But the race is a long one, the chances of life, and a high rate of interest in the country, make it one of no ordinary risk, and it is one that holds out no prospect of any return in less than ten years. A person commencing and stopping short of the bearing point, either by death or want of funds, will suffer almost total loss, for the value of such a property brought into a market where there are no buyers must be purely nominal. Again, if the property has arrived at the paying point, almost any person of common honesty can take charge of and carry it on, for the trees after twelve years are remarkably hardy, and bear a deal of ill treatment and neglect: not that I would recommend any person to try the experiment. But it is some consolation for the proprietor to know that stupidity will not ruin him, and that even at the distance of thousands of miles he can give such directions, as if attended to, will keep his estate in a flourishing and fruitful state. The total number of nutmeg trees in Singapore in 1848 was 55,925, of which 14,914 only were in bearing. The produce of that year was 1,085,361 nutmegs, or 23,600 lbs. in weight. The greater number of the trees, it will be perceived, have not come into full bearing, but the produce is increasing rapidly, and in 1849 it amounted to fully 66,670 lbs. Among the principal growers in that island are Dr. Oxley, Mr. C. R. Prinsep, and Mr. W. Montgomerie, who have each large plantations, with from 2,000 to 5,000 bearing trees on them. Others, as Sir J. d'Almeida, Mr. Nicol, and one or two more, have planted extensively, but have not yet got their trees to the bearing point. A large supply of nutmeg and clove plants arrived at Pinang in 1802, from the Molucca Islands. There were 71,266 nutmeg and 55,264 clove plants; allowing one half of the former to have been male trees, there would only have been 35,633 useful nutmeg plants. It is believed that a mere fraction of these ever reached maturity, but they served to introduce the cultivation permanently. Plants were likewise sent to Ceylon and Cape Comorin. It does not appear that the climates of these two localities suit the nutmeg tree, as it requires rain, or at least a very damp climate throughout the

year. The East India Company's spice plantations in Pinang were sold in 1824, and the trees were dispersed over the island. The spice cultivators of the Straits' Settlements have for sometime sought a further protective duty on nutmegs, and the extension of a similar protection to mace and cloves, the produce of these settlements; for singularly enough the present tariff affords no protection to mace, the growth of British possessions. From tabular statements, furnished by the Chamber of Commerce of Pinang, drawn up apparently with great care, it appears that in 1843 there were 3,046 acres cultivated with spice trees in Pinang and Province Wellesley, containing 233,995 nutmeg, and 80,418 clove trees, besides 77,671 trees in nurseries ready to be planted out; and by a similar statement from Singapore, which is however not so complete, that 743 acres are cultivated, containing 43,544 nutmeg trees. The island of Pinang is estimated to contain 160 square miles, nearly the whole of which, with the exception perhaps of summits of the hills, is well adapted to spice growing. Province Wellesley is of much greater extent, and the soil of it has already ben proved to be equally well fitted for that kind of cultivation; and the settlements of Malacca and Singapore are said to be admirably suited, in many places, for that species of produce, the latter of which has already several plantations fast approaching to maturity. The cultivation is capable of great extension: encouragement is only required to be held out, and new plantations will be rapidly formed in these settlements. The same tables show that the produce in 1842 was, in Pinang and Province Wellesley, 18,560,281 nutmegs, 42,866 lbs. of mace, and 11,813 lb. cloves; Although this was the amount of produce for 1842, it must be remarked that crop was a complete failure, and the average crop for some years past has been 46,666 pounds, and in Singapore, 812,328 nutmegs, and 1,962 lbs. of mace. Thus making the produce from the two settlements 19,408,608 nutmegs in number (or in weight 147,034 lbs.), 44,822 lbs. of mace, and 11,813 lbs. of cloves. Now the consumption of these spices in Great Britain was, on an average of four years ending 1841, as follows:—Nutmegs, 121,000 lbs.; mace, 18,000 lbs.; cloves, 92,000 lbs. Showing, therefore, that the Straits' Settlements already produce more than sufficient of the two former to supply the home market. In the course of four or five years more, Pinang alone will more than double the present quantity of nutmegs and mace produced in the Straits, and the produce of cloves will be more than tripled. Simmonds has been able, from several elaborate papers in his "Colonial Magazine," to condense details, showing the progress of spice plantations in Prince of Wales Island and Province Wellesley. In the close of 1843 there were 64,902 nutmeg trees in bearing in the Island; 39,209 male trees, 103,982 not bearing; making a total of 208,093 trees planted out, besides 52,510 plants in nursery. The quantity of ground under cultivation was 2,282 orlongs. The produce in 1842 was 15,116,591 good nuts, 1,461,226 inferior nuts, and 38,269 lbs. of mace. The gross value of the produce in 1843, reckoning the good nuts at five dollars per thousand, and the inferior at one dollar, was 76,944 dollars. The estimated number of nuts in 1843 was 12,458,762; in 1844, 25,429,000. In Province Wellesley there were 247 orlongs under cultivation with the nutmeg, on which were 10,500 bearing trees, 8,005 male trees, and 7,307 not yet bearing, making in all 25,902 trees planted out. The produce was in 1842, 1,969,619 good nuts, 18,842 inferior ditto, and 4,500 lbs. of mace. The value of the produce of nutmegs was 9867 dollars. The estimated number of nuts in 1843 was 1,980,000; in 1844, 2,958,000. They were in all 423 nutmeg plantations on the island and main land. There were annually exported in the four years ending 1850, 48,000 lbs. of nutmegs from Pinang, and 57,400 lbs. of mace. The French at an early period cultivated the nutmeg at the Mauritius, and from thence they carried it to Cayenne. In Sumatra it appears to have been grown successfully, and according to Sir S. Raffles, there was in 1819 a plantation at Bencoolen of 100,000 nutmeg trees, one-fourth of which were bearing. Attempts have been made in Trinidad and St. Vincent to carry out the culture, but for want of enterprise very little progress seems to have been made in the matter. Under the duties which came into operation in 1854, nutmegs, instead of standing at 1s. per pound all round, have been classified, and the so called "wild" nutmegs of the Dutch islands are to pay only 5d per pound. This deprives the Straits' produce of its last protection against that of the Banda plantations, where the tree grows spontaneously, while it gives the long Dutch nut a high protection. If an alteration in this suicidal measure is not speedily obtained, the Straits' planters will be ruined. The Dutch have the power of inundating the market with the long aromatic nut. If the original plan of putting all British and all foreign nutmegs on the same footing had been adhered to, the Straits' planters would not have complained, as they would have trusted to their superior skill and care to compensate for the grand advantage the Dutch have in their rich soils. On observing this alteration of duty, Mr. Crawfurd and Mr. Gilman immediately prepared the following memorandum for the Chancellor of the Exchequer, which however failed to influence that minister:—

Memorandum on the Duties of Nutmegs.—"The duty proposed to be levied on nutmegs is 1s. per pound for cultivated, and 5d. per pound

for those commonly called wild. The ground on which this distinction is founded, is said to be that the market value of the one is but half that of the other, and that the Customs can readily distinguish between them. Now it is admitted, on all sides, that there is but one species of culinary nutmeg, the *Myristica Moschata* of botanists, although at least a score of the same genus, all unfit for human food. The parent country of the aromatic nutmegs extends from the Molucca Islands to New Guinea, inclusive. In this they grow with facility, and even in the Banda Islands, where there are parks of them, they hardly undergo any cultivation, and may truly be said, even there to be a wild product. It is only when grown as exotics, as in the British settlements of Pinang and Singapore, that they require cultivation, and that a more careful and expensive one than any other produce of the soil. Aromatic nutmegs are sometimes large and sometimes small—sometimes round, sometimes oblong, and sometimes long, and this will be found the case whether cultivated or uncultivated. How, then, the Customs are able to distinguish them it is difficult to understand. In the ordinary Prices Current no mention whatever is made of the wild and cultivated, the lowest quality being quoted in the most recent at 2*s.* per pound, and the highest at 3s. 10d.,—the best of what are called wild fetching a higher price than the lower qualities of what are called cultivated. But suppose the distinction could be made with the most perfect certainty, to make it would be a palpable departure from the principle adopted with every other commodity, of charging a uniform rate of duty on quality. To give an example, the present price of black pepper is 3¾d. to 4d. per pound, while that of white pepper is 8½d to 1s. 2d. per pound, both paying the same duty of 6d.; yet nothing can be more easily distinguished than these two commodities, which, except as to curing, are the same article. Tea is a still more striking example. The duty is the same on all qualities, though prices range from 11½d. to 3s. 6d. per pound. It was the very circumstance of the difficulty of distinguishing between the different kinds of tea, especially between Bohea and Congou, which, after an eighteen months trial, overthrew the system of rated duties of 1s. 6d., 2s., and 3s., adopted on the abolition of the East India Company's monopoly in 1833. Unless the duty on nutmegs is equalised there will be no end of trouble and disputes, and however expert the Customs may be, they will certainly be outwitted, and long-shaped and small nutmegs, although really cultivated, will be introduced at the lower duty, by unscrupulous traders, as wild ones. It may be added that duties of 12d. and 5d. do not, even if a departure from the principle of charging on quality were justifiable, represent the just proportional rates which ought to be levied upon what are supposed to be, respectively, cultivated and wild, as they are represented in the ordinary Price Current by the highest and lowest prices, which are 3s. 10d. and 2s. The just proportional duty ought to be on the lowest, not 5d., but 7d. The duty, as first proposed by the Chancellor of the Exchequer, of 1s. per pound on nutmegs, without distinction, was perfectly satisfactory to the planters, merchants, and the trade in general. It is a mistake to suppose that a duty of 1s. would exclude the so-called wild nutmegs. They would be imported in large quantities, as the cost is low. In quantity it was 17 Spanish dollars per picul, and there is no reason to suppose it would be more now. The finest picked cost say 34 Spanish dollars. In Pinang and Singapore, for cultivated the price is 65 to 70 dollars. The planters for the most part do not sell on the spot, but consign here for sale on their own account. London, May 23d, 1853.

—*Simmonds.* In the Penang papers for 1857, the *Gazttee* gives the following statistics: The subjoined table of the exports of Nutmegs and Mace from Penang during the last ten official years shows a startling rate of increase. The exports in 1855 1856, 4624 piculs of nutmegs and 1340 of mace—exceed the total produce of the Bandas in 1855, which Dr. Oxley states at 4032 piculs of nutmeg and 1008 of mace. When the Singapore produce is brought into the account, it will appear that the British production of this spice now considerably exceeds the Dutch. The consumption in Europe and America has, we believe, more than doubled during the last five years, and if the preposterous duty were reduced to reasonable limits and the protection to the Dutch wild nutmeg withdrawn, we have little doubt the

production and demand would go on improving in a still greater ratio, to the manifest advantage of this Settlement.—*Penang Gazette.*

109 piculs of imported mace were also re-shipped in 1847. 40,000 lbs. of mace were imported into the United Kingdom from India in 1848.—*Simmonds.*

(5690) NUTMEG BUTTER. MYRISTICA MOSCHATA.

Jadipoorie Thuli, TAM. | Jaiphul ka Tael, HIND.
Jajikaya enney, TEL.

Is obtained by expression from the nutmeg, it has an aromatic smell from the volatile oil it contains.—*M. E. J. R.*

(5691) NUTMEG OIL.

Jaiphul-ka-teil, HIND.

The Nutmeg contains a fixed or solid oil, and a volatile oil; both of which are used for medical purposes. Of the former there are two varieties; the English, which is the best, occurs in pieces of about ¼ lb in weight, wrapped in leaves of the banana, it has a uniform reddish colour inside; and the Dutch, imported from the Moluccas chiefly, in larger pieces, wrapped in leaves or paper, and of a lighter colour. *Waterston.—Faulkner.*

(5692) NUTMEGS, MALE.

Kayphul, GUZ. and HIND.

A native of the Moluccas, and frequently to be met with in some of the woods of Southern India. It is covered with a hard shell, provided with a pale arillus. It is one and a half to two inches long, elliptical, the parenchyme devoid of marbling. Its odour is weak, and flavour disagreeable. Its properties are analogous to that of the true Nutmeg, but the oil is so inferior in proportion, that it is but of little commercial value. It is thought that it might, however, be greatly improved by cultivation. They are procurable in most Indian bazars.—*Faulkner.*

(5693) NUTS, ACHEEN, are the betel nut, boiled, of very inferior quality, chiefly used by the lower classes in the South of India and are in no demand at Madras: sold from 35 to 50 Rs. a Candy.

(5694) NUTS, COLUMBO, are raw betel nuts: sold every where and are chiefly used by the Kayala, a class of Mahomedans.

(5695) NUX VOMICA, POISON NUT.

Nux Vomica, Semina Seeds.
Strychnos Nux Vomica, Lin
Nux Vomica, or Koochla tree.
Pentand. Monog. Linn.

Nux Vomica was early used as a medicine by the Hindoos; it is their *Koochla* tree (Sans. Culaka, and Kataka), and being a produce of India, its properties must have been investigated long before it could be known to foreign nations. It is the *Izarakee* of Persian works on Materia Medica, but there is doubt respecting its name in Avicenna. *Khanuk-al-kulb*, dog-killer, and *Faloos mahee*, fish-scale, are other Arabic names. But under the name of *Jouz-al-Kue* or Emetic Nut, Dr. Royle obtained the fruit of a Rubiaceous shrub. Dr. Pereira thinks that the *Nux Meshil* of Serapion is Nux Vomica; but in Persian works this name is applied to a Datura.

The plant is a moderate sized tree, with a short crooked trunk. Branches irregular, the young

ones long and flexuose, with smooth dark grey bark. Wood white, close-grained, and bitter. Leaves opposite, with short petioles, oval, smooth, and shining, 3 to 5-nerved, differing in size. Flowers small, greenish-white, in terminal corymbs. Calyx 5-toothed. Corol funnel-shaped; limb 5 cleft, valvate. Stamens 5; filaments short, inserted over the bottom of the divisions of the calyx; anthers oblong, half exserted. Ovary 2-celled, with many ovules in each cell, attached to the thickened centre of the partition. Style equal to the corol in length. Stigma capitate. Berry round, smooth, about the size of an orange, covered with a smooth somewhat hard fragile shell, of a rich orange-colour when ripe, filled with a soft white gelatinous pulp, in which are immersed the seeds attached to a central placenta. Seeds peltate or shield-like, slightly hollowed on one side, convex on the other, about ¾ of an inch in diameter, and about 2 lines in thickness, thickly covered with silky ash coloured hairs attached to a fibrous testa, which envelopes the kernel composed of horny bitter albumen, of the form of the seed and of the embryo imbedded in a hollow in its circumference.—Roxb. Corom. i. t. 4.—A native of the Indian Archipelago and of the forests of the Peninsula of India, as well as of the Southern parts of the Bengal Presidency, as near Midnapore.—Esenb. and Eberm. 209. St. and Ch. 11. 52.

Lignum Colubrinum, supposed to be an antidote against the poison of venomous snakes, as well as a cure for intermittent fevers, is produced by other species, as *Strychnos ligustrina* and *S. Colubrina*. *S. Tiente* yields the *Upas tieute* and *Tjettek* of the Javanese, which is an aqueous extract of the bark. *S. toxifera* yields the *Woorali* or *Ourari* poison of Guyana. *S. pseudoquina* is employed in Brazil as a substitute for Cinchona Bark, and the seeds of *S. potatorum*, Roxb., *nirmulee* of the Hindoos, are employed by them to clear muddy water.

Strychnos Ignatia, usually considered as constituting a distinct genus, and called *Ignatia amara*, Linn. is however of most importance, as its seeds called St. Ignatius's beans, are frequently made to yield their Strychnia. They are ovate, triangular, of a reddish-gray colour, and about twenty of them contained in a pear-shaped fruit. They are produced in the Philippine islands, and have long been used in India, where they are called *Papeeta*, and are mentioned in the work called Taleef Shereef. They are intensely bitter, and contain a larger quantity of Strychnia than the Nux Vomica seeds.

The wood of Nux Vomica tree is said by Dr. Christison to be often substituted for the *Lignum Colubrinum*, or Snake-wood. The Bark is unfortunately sold in many shops in Calcutta under the name of *Rohin*, and thus substituted for the febrifuge bark of the *Rohuna tree*, or *Soymida febrifuga* (Beng. Disp. pp. 247 and 437), which was made known by Dr. Roxburgh, written on by Dr. Duncan in 1794, and introduced into the E. P. In this way probably it came to be introduced into England, and not being found saleable, was sent to Holland, and there sold and used as Angustura-bark (v. p. 325), supposed at one time to be the bark of Brucea ferruginea. In 1804, Dr. Ronbach of Hamburgh observed that it acted as a poison, and as several fatal cases occurred, it was in consequence prohibited being used in many Continental states. From its composition, Batka suspected that it was the bark of the Nux Vomica tree, or of some allied species. This Dr. Pereira confirmed by examining the specimens of Strychnos Nux Vomica in the East Indian Herbarium. (Med. Gaz. xix. p. 492.) Dr. Christison, as he informed Dr. Royle, came to the same result by examining specimens of Nux Vomica bark with French specimens of false Angustura Bark.

Dr. O'Shaughnessy in Calcutta, fully established the identity of false Angustura bark, and of the bark of the Nux Vomica tree in Journ. of Med. and Phys. Soc. of Calcutta, Jan. 1837; in consequence of an alkali having been obtained from what was supposed to be the bark of the *Soymida febrifuga*, but which proved to be the bark of Strychnos Nux Vomica. The whole forms a most instructive lesson on the absolute necessity of being thoroughly acquainted with the true nature of the drugs we prescribe.

Nux Vomica Bark is in flattish or slightly curved pieces, thick, hard, and compact; fracture dull and brownish; epidermis sometimes displaying a ferruginous, spongy, and friable efflorescence, at other times a yellowish-grey colour, marked with prominent greyish-white spots. Both appearances are due to alterations in the texture of the epidermis, and not to lichens, which are rare. The bark is smooth internally, its powder of a yellowish-white colour, without smell, but having an intense and permanent bitter taste. A drop of Nitrickacid on the external ferruginous part, turns it of a dark greenish colour; but if applied to a transverse section or internally, a dark-red spot is produced. Analysed by Pelletier and Caventou, it yielded Brucia. Dr. Christison states that it might be employed for obtaining Strychnia. An infusion of the Bark slightly reddens Litmus, Nitric acid produces in it a red, and Sulphate of Iron a green colour, but an infusion of galls a greyish-white precipitate.

Nux Vomica Seeds are round and flat, or rather shield-like, of a light-greyish colour, covered with a thick and tough testa, silky with fine hairs, which assist in detecting it when in powder and magnified. The seeds have little smell, but an intense and tenacious bitter taste; are so tough, that the E. C. give directions for powdering them (v. Extract). The powder, put

to be adulterated with substances employed to assist in pulverization, is of a yellowish-fawn colour. Water takes up some, but Proof and Rectified Spirit nearly all its active properties. Analysed by Pelletier and Caventou, the seeds were found to contain two alkalis, *Strychnia* and *Brucia* united with a pecular acid, the *Igasuric*, called also Strychine acid, a yellow Colouring matter, a Concrete Oil, Gum, Starch, Passorin, and a small quantity of Wax.

Action. Uses. Cerebro-Spinant, Poisonous, producing tetanic convulsions without affecting the brain. Used as a Stimulant of the Nervous System in Paralysis, in doses of the powder gr. v.–gr. xv. or other effective preparations may be employed.—*Royle.*

This is well known for the delicious though evanescent perfume of its flowers.—*O'Shaughnessy, p.* 436. The delicate sweet smelling flowers of this shrub, or rather the tube of their corollas, called in Hindooie (Dundee), are of a fine rich yellow colour and are employed alone or in conjunction with Parasam flowers (Butea frondosa), in preparing a beautiful bright yellow dye much sought after by the Mahometans for dyeing their turbans.—*Ains. Mat. Med. page* 148. In Ajmeer, cultivated as a rare flower the blossoms are very fragrant and there the tubes of the corolla are used, under the name of "kesru," to dye buff or orange colour. This plant is very abundant, wild at the foot of the Vindhya range, where the green tough stalks are used to make large grain baskets of—*Gen. Med. Top. p.* 172. The tree of mourning, sometimes called night-blooming flower, is as great a favorite in India as in the Southern States of America. Its delicate orange and white blossoms pour the most delicious fragrance on the evening air, and then fall in showers, bedewing the earth's cold bosom with sweetness.—*Mason.*

(5698) NYMPHÆA, a genus of Plants the type of the natural order *Nymphæaceæ*. It has a calyx of 4 sepals girding the base of the torus. The petals, 16 to 28, adnate to the torus, elevated about the ovary and covering the same, and therefore at first sight appearing inserted into it. The stamens are numerous, disposed in many series, and inserted in a similar way above the petals. There are upwards of 20 species of this genus described. They have all large floating leaves, with white, red, or blue flowers, which appear at the surface of the water.—*Eng. Cyc.*

(5699) NYMPHÆA, water lily. Griffith says there are two different species of water lily in the Tenasserim Province.—*Mason.*

(5700) NYMPHÆA ALBA, the common White Water-Lily, has cordate quite entire leaves: the stigmas 16-rayed, the rays ascending. This plant is a native of ditches, ponds, and lakes throughout Europe, and is abundant in Great Britain. The flowers are white, and according to Linnæus, open themselves in the morning at seven o'clock, and close them at four o'clock in the evening. This plant is very deservedly highly esteemed as the most beautiful of European plants. It is frequently accompanied with the yellow water-lily, and the two together give an exceedingly graceful appearance to the waters they occupy. The roots of the White Water-Lily contain an astringent principle, which renders them useful in dyeing. They also contain starch, and on this account swine feed on them, although other animals reject them. The whole plant was at one time regarded as medicinal, but is now seldom employed by medical men, although it has a popular reputation as a remedy in many diseases. There is a variety of this plant occasionally met with called *alba minor*, which has smaller flowers and leaves than the species.—*Eng. Cyc.* Found in tanks in India, and grown as the rest of the species.—*Riddell.*

(5701) NYMPHÆA CERULEA, Blue Water-Lily, has peltate nearly entire leaves without dots, glabrous on both surface, and 2-lobed at the base, the lobes free; the anther with an appendage at the apex; the stigmas 16 rayed. This plant is a native of Lower Egypt in rice-grounds and canals about Rosetta, Damietta, and Cairo. The flowers are very fragrant, and from its frequent representation in the sculptures of Egypt, it appears to have been regarded as a sacred plant by the ancient Egyptians.—*Eng. Cyc.*

(5702) NYMPHÆA CYANEA, BLUE LOTUS.

Neel Padma Lila Phool, HIND.

The plant is common in the Ajmeer and Poshkur lake: the flowers are used medicinally; being considered astringent and refrigerant.—*Genl. Med. Top. p.* 144 and 198.

(5703) NYMPHÆA EDULIS, the Eatable Water Lily, has peltate broad oval entire leaves, with the under surface pubescent. This plant is a native of the East Indies, in wet fenny districts. Its flowers are small, and white or reddish. Like all the species, it has large pear-shaped roots, which contain an abundance of starch, and they are consequently used as articles of diet. The seeds also of a species nearly allied

to this, the *N. rubra*, which has deep-red flowers, are also used as an article of diet. Its flowers also are held in superstitious veneration by the Hindoos in the districts of the East Indies in which it grows.—*Eng. Cyc.* Dr. Riddell says *Nymphæa Esculenta*, has a tuberous root, which is eaten and held in esteem by the Natives. —*Riddell.*

(5704) NYMPHÆA LOTUS. Lin.

Kakikulluvagudda, Tel. | Allie kasung, Tam
Koee, Kumuda, Kumul, Hind. | Cahlara also Caco-utpala, Sans.

At Poshkur, Sambhur, &c.—*Genl. Med. Top. page* 198. *Ainslie p.* 248. *Nymphæa Lotus*, the Egyptian Lotus, has peltate leaves, sharply serrated; the under surface is pilose at the nerves, and pubescent between them. This plant is a native of Egypt, and grows in slow-running streams, especially in the Nile near Rosetta and Damietta and is found in rice-fields during the time they are under water. It has large white flowers, with the sepals red at the margins. The roots are large, tuberous, and eatable. The seeds dried were made into a bread by the ancient Egyptians, and the roots were employed in the same manner. This plant is regarded with superstitious veneration by the Egyptians. It resembles the Nelumbo of the Hindoos, a plant belonging to the same natural order, and called the True or East Indian Lotus. The latter has always been regarded as the emblem of fertility. Lotus is a name applied to various plants by the ancients. The Lotus of the *Lotophagi* was the *Zizyphus Lotus*; that of Homer and Dioscorides, a species of *Lotus*, or *Trifolium*. The Lotus of Hippocrates is the *Celtis Australis*; and the Italian Lotus is the *Diospyrus Lotus.—Eng. Cyc.* Its root, like that of the Tawmaray, (Nelumbium speciosum), can only be found, in dry weather, in the beds of the tanks. It is pleasant to the taste, and is made by the Natives into curries and other dishes.—*Ainslie, p.* 248. Dr. Buist has lately given the scientific world a highly interesting account of the breathing of the Lotus.

(5705) NYMPHÆA ODORATA, Sweet-Scented Water-Lily has cordate quite entire leaves, with the nerves and veins on the under surface very prominent; the stigmas 16-to 20-rayed; the rays erect, inflexed at the top. This plant is a native of North America, from Canada to the Carolinas; it is found in deep ditches and slow-running rivers. This plant is often confounded with the European Lily, but it is quite distinct. Its flowers are white tinged with red, very fragrant; they open in the morning, and close at noon. The root is astringent, and much more powerful than the last species. It contains tannin and gallic acid and a decoction of the root gives a black precipitate, with sulphate of iron. The root is used by medical men in America as an astringent, and is employed by the people for making poultices.—*Eng. Cyc.*

(5706) NYMPHÆA ODORATA.

The flower.

Shengalaneer poo, Tam. | Ructaootepala, Sans.

This beautiful lilac coloured flower ought to have had a place amongst the flowers: it has a most delightful smell, somewhat like the wall flower, and is sacred both to Sheva and to Vishnoo.—*Ainslie's Mat. Med. p.* 301.

(5707) NYMPHÆA PUBESCENS.

Koee Kummell, Hind.

A variety of the last, bears a white flower.—*Riddell. N. pubescens* has peltate, sharply-toothed leaves, orbicularly reniform, with the under surface pubescent and spotted, and the lobes roundish. It is a native of the East Indies, Malabar, Moluccas, Tranquebar, Ceylon, Java, and has been also found at Waree and Acra on the western coast of Africa. This plant is called Lotus throughout India, and is held sacred by the Hindoos. Its flowers are of a beautiful white. They expand during the day and close at night, and exhale a strong vinous odour.—*Eng. Cyc.*

(5708) NYMPHÆA PYGMIA. *Hypericum* and *Parnassia*; also a diminutive water-lily, the flower of which is no larger than a half-crown; grow on the Khasia Hills. The latter is the *Nymphæa pygmæa* of China and Siberia a remarkable fact in the geographical distribution of plants.—*Hooker, Him. Jour. Vol.* II. *p.* 312.

(5709) NYMPHÆA ROSACEA. Pink water lily.

Kumbula Rukla, Hind.

Cultivated in tanks, and also wild at Poshkur &c.—*Gen. Med. Top. p.* 198.

(5710) NYMPHÆA RUBRA.

Kummul, Hind.

Red flowering lotus. In tanks, flowers about the close of the rains—of a dark crimson colour. —*Riddell.*

(5711) NYMPHÆA STELLATA. This plant is common in ponds and tanks. The flowers are blue.—*Riddell.*

(5712) NYMPHÆACEÆ, a natural order of Aquatic Plants, with floating leaves and solitary flowers, found in all the hot and temperate parts of the world. They usually have 4 sepals and many petals, which latter gradually contract into stamens, indefinite in number, and either hypogynous or adherent to the sides of the carpels. The ovary is superior, divided internally into numerous cells, to whose sides adhere many seeds, containing an abundance of albumen and a small embryo external to it: the stigmas radiate from the apex of the ovary. The order dif-

fers from *Ranunculaceæ* in the consolidation of its carpels, from *Papaveraceæ* in the placentation not being parietal, and from *Nelumbiaceæ* in the want of a large truncated disc containing monospermous achenia. The stems of these plants are fleshy rhizomata, rooting in the mud at the bottom of the waters in which they grow; and their woody tissue is so loosely disposed among the cellular, as to have given rise to a controversy concerning the real nature of the plan on which it is arranged, most writers considering that it is exogenous while others refer it to the endogenous type. The species of this order are generally plants of great beauty, either the flowers or the leaves being of unusual size. The White Water-Lily (the *Nymphæa alba*) and the yellow (Nuphar luteum) of English rivers and ponds are among the finest specimens of floral development in northern latitudes. In other countries both their size and colour are augmented, brilliant hues of blue and crimson being added to the pure white of the northern species and the most delicious odour being emitted. In Demerara grows the Victoria regia, whose flowers have a diameter of 15 inches while the leaves are as much as 6½ feet across. In the East Indies, the Euryale ferox emulates the Victoria in the size of its leaves but its flowers are small and inconspicuous. In both these plants the farinaceous seeds are used for food. Barclay is another genus belonging to this order. The genera contain about 50 species.—*Eng. Cyc.*

O.

(5713) OADHAL, Sterculia Villosa, called *Oadal* in Assam, is native of the mountainous countries to the eastward of Bengal. Trunk straight. The bark is smooth, but fibrous bags are made of it. Its fibres are made into cords by the natives of the eastern frontier of Bengal, to bind wild elephants with. Of a coil of *Oadal* rope, Major Jenkins gave the following notice in the year 1847: "The *Oadal tree* is very common, and the rope is made most readily; the bark, or rather all the layers, can be stripped off from the bottom to the top of the tree with the greatest facility, and fine pliable ropes may be made from the inner layers of bark, whilst the outer yield coarse ropes. The rope is very strong and very lasting—wet doing it little injury." *Oadal* is a creeper in Kemaon, with fine, strong fibres.

(5714) OAK.

Baalut, Arab.	Quercus, Lat.
Eeg, Dan.	Dab, Pol.
Eik, Dut.	Roble Carbahlo, Port.
Chene, Fr.	Dub, Rus.
Eiche, Ger.	Roble, Sp.
Quercia, It	Ek, Sw.

A genus of well-known timber trees (*Quercus.*) embracing about 150 species.—*Faulkner.* Several species are indigenous in the Tenasserim provinces—*Mason.*—and on the mountains of Southern India.—*Wight.* Wallich found seven different species of oak Quercus fenestrata, turbinata, velutina, Amherstianus, Tirbhæ, growing in Burmah and on the Tenasserim Coast, and all afford useful timber, though inferior to the English oak.—*Mason.* No oak nor chesnut ascends above 9000 feet in the interior of Sikkim, where they are replaced by a species of hazel (Corylus); in the North Himalaya, on the other hand, an oak (*Quercus semecarpifolia*, see vol. i. p. 187) is amongst the most alpine trees, and the nut is a different species, more resembling the European. On the outer Sikkim ranges oaks (Q. annulata ?) ascend to 10,000 feet, and there is no hazel.—*Hooker, Him. Journal. Vol.* II. *page* 140. It is not generally known that oaks are often very tropical plants; not only abounding at low elevations in the mountains, but descending in abundance to the level of the sea. Though little known in Ceylon, the Peninsula of India, tropical Africa, or South America, they abound in the hot valleys of the Eastern Himalaya, East Bengal, Malay Peninsula, and Indian islands; where perhaps more species grow than in any other part of the world. Such facts as this disturb our preconceived notions of the geographical distribution of the most familiar tribes of plants, and throw great doubt on the conclusions which fossil plants are supposed to indicate.—*Hooker, Him. Jour Vol.* II. *p.* 336.

(5715) OAKUM.

Oakum, Guz. & Hind.

A term applied to old hempen ropes pulled loose, and used in the caulking of sailing vessels. —*Faulkner.*

(5716) OATS, Avena. The Common Oat Tribe, *Aveneæ.*

Havre, Dan.	Owies, Pol.
Haver, Dut.	Aveia, Port.
Avoine, Fr.	Owes. Rus.
Hafer, Ger.	Avena, Sp.
Vena, Avena. It.	
Semina integumentis nudata, L.	Farina ex seminibus, D. Oatmeal.
Seeds, E. of Avena sativa, Linn.	

The Oat (*Βρῶμος* of Dioscorides) was known to the Greeks. The Oat is distinguished among cereal grains by its loose panicle. Spikelets 3-2

flowered. Florets smaller than the glumes, naked at the base, alternately awned. Outer palea with lateral nerves, awned, ending in 2 points. Awn dorsal, kneed and twisted. Stamens 3. Ovary hairy at the top. Stigmas 2. Scales 2. Grain long, crested, and furrowed.—A native probably of the Persian region. Several varieties are cultivated in Europe.—Nees von E. 28. The grains of Oat when deprived of their integuments form *Groats*, when these are crushed, *Embden* and *Prepared Groats*. When the grain is kiln-dried, stripped of its husk and delicate outer skin, and then coarsely ground, it constitutes the *oatmeal* of Scotland. "The husk, with some adhering starch from the seed, is sold under the inconsistent name of *Seeds*." Oats, according to Vogel, consist of 34 of husk and 66 per cent. of meal, and Oatmeal, in 100 parts, of 59 of Starch, 4·3 of Albuminous matter, Bitter Extractive and Sugar 8·25, Gum 2·5, with 23·95 of Lignin and moisture. Dr. Christison finds as much as 72 per cent. of Starch, and that it consists therefore of nearly five-sixths of real nutriment. *Action. Uses.* Groats and Oatmeal are nutrient and demulcent. When boiled with water (3 oz. to Aq.Oj. boiled to Oss.) Gruel is formed, which is so useful as diet for the sick. Oatmeal, when of thicker consistence, forms Porridge, and may be employed for making poultices.—*Royle.* Oats are principally in demand for horses, and the extraordinary increase of the latter has occasioned a proportional increase in the culture of this grain in Britain. They are grown more especially in the north and north-eastern counties; in the midland counties their culture is less extensive, but it is prevalent throughout most parts of Wales. Nearly twice as much oats as wheat is raised in the United Kingdom, but the proportion grown in Scotland is not so large as is supposed. The following is a fair estimate of the comparative production:—

	Acres.	Produce.
England	2,500,000	12,500,000
Ireland	2,300,000	11,500,000
Scotland	1,300,000	6,500,000
Total	6,100,000	30,500,000

England imports annually about 1¼ million quarters from foreign countries and nearly three-fourths of a million quarters from Ireland. The average produce per acre throughout the kingdom is five quarters. The price within the last 10 years has ranged from 28s. 7d. per quarter (the famine year) to 17s. 6d. The oat, when considered in connection with the artificial grasses, and the nourishment and improvement it affords to live stock, may be regarded as one of the most important crops produced. Its history is highly interesting, from the circumstance that in many portions of Europe it is formed into meal, and forms an important aliment for man; one sort, at least, has been cultivated from the days of Pliny, on account of its fitness as an article of diet for the sick. The country of its origin is somewhat uncertain, though the most common variety is said to be indigenous to the Island of Juan Fernandez. Another oat, resembling the cultivated variety, is also found growing wild in California. This plant was introduced into the North American Colonies soon after their settlement by the English. It was sown by Gosnold on the Elizabeth Island in 1602; cultivated in Newfoundland in 1622, and in Virginia, by Berkley, prior to 1648. The oat is a hardy grain, and is suited to climates too hot and too cold either for wheat or rye. Indeed, its flexibility is so great, that it is cultivated with success in Bengal as low as latitude twenty-five degrees North, but refuses to yield profitable crops as we approach the equator. It flourishes remarkably well, when due regard is paid to the selection of varieties, throughout the inhabited parts of Europe, the northern and central portions of Asia, Australia, Southern and Northern Africa, the cultivated regions of nearly all North America, and a large portion of South America. In the United States the growth of the oat is confined principally to the Middle, Western and Northern States. The varieties cultivated are the common white, the black, the grey, the imperial, the Hopetown, the Polish, the Egyptian, and the potato oat. The yield of the common varieties varies from forty to ninety bushels and upwards per acre, and weighing from twenty-five to fifty pounds to the bushel. The Egyptian oat is cultivated south of Tennessee, which after being sown in autumn, and fed off by stock in winter and spring, yields from ten to twenty bushels per acre. In the manufacture of malt and spirituous liquors oats enter but lightly, and their consumption for this purpose does not exceed 60,000 bushels annually in the United States. In 1840, Ireland exported 2,037,835 quarters of oats and oatmeal, but in 1846, on account of the dearth, the grain exports fell off completely. Most of the grain grown in Ireland requires to be kiln-dried, and is, therefore, of lower value. The oat, like rye, never has entered much into the foreign commerce, of Britain as the domestic consumption has always been nearly equal to the quantity produced. The annual average exports from the United States for several years preceding 1817, were 70,000 bushels. By the census returns of 1840, the total produce of the United States was 123,071,341 bushels; of 1850, 146,878,879 bushels. In Prussia 43 million hectolitres of oats are annually raised. The quantity of oats imported into the United Kingdom, has been declining within the last few years. In 1849, imported 1,267,106 quarters; in 1850, 1,154,473; in 1851, 1,2 9,844; in 1852 995,479. In 1844, 221,105 bushels of oats were raised in Van Diemen's Land on 13,864 acres. The flour of oats ground rather coarsely, is

used as an article of food both in Scotland and in the north of England. It is prepared in various ways, chiefly as porridge, and baked into cakes. Although Oat-flour is obtained, in England, from the Avena Sativa, there are several distinct species of Oats. The oat grains or seeds are usually enclosed in their husks; when deprived of these, they are termed "groats; and these crushed constitute Embden groats.—*Hassell.* It is the hardiest of all cereal grains cultivated in Britain, of which there are about 40 species known to botanists.

(5717) OBBAIRIA, Hard, rather fine, generally close-grained, Ceylon wood, presenting, however, many open cells; heavy.

(5718) OCHRE. (YELLOW). SONAGAROO (RED).

Pewdee, HIND. GUZ.

An earthy mixture of alumina, silica, oxide of iron, and other substances, found in beds in various parts of England, India, on the Continent, &c. It is generally of a yellow or brown colour, but is sometimes reddened by calcination. It is prepared for use by grinding and elutriation; and is employed as an ingredient in painter's colours, in the polishing of metals and stones, and for other purposes.—*Faulkner.* Ochre sometimes contains a little calcareous matter and magnesia. The oxide of iron may occur in so large a proportion that the ochre becomes an ore of that metal. Ochre is found in beds some feet thick, generally above the oolite, and covered by sandstone and quartzose sands more or less ferruginous, and accompanied by grey plastic clays of a yellowish or reddish colour. All these substances enter into the composition of the ochres. The ochry earths are ground under edge millstones and elutriated for use: the yellow ochres may be changed into red or reddish brown by calcination, whereby the iron is raised to a higher degree of oxidation. Native red ochre is also called *red chalk* and *reddle or Bole.*

(5719) OCHRA, OR OKRO, ABELMOSCHUS ESQULENTUS. A plant of which the fruit is used as a vegetable in the West Indies, the United States, and in South America, and which is remarkable for the similarity of its name to the vegetable called Ochra by the Greeks, but which has not been ascertained by botanists. The names by which the produce of the New World is distinguished in the works of Marcgrave and Piso are Quingambo and Quigombo, and in the later works by that of Gombo and Gombaut or Gombeau. It is possible, therefore that a classical name which was not otherwise engaged may have been applied to a new vegetable, and, as has been the case in many instances, without any attempt being made to identify the plant named with that which had been described by classical authors. This plant is the Hibiscus esculentus of authors [Hibiscus] —*English Cyclopædia page* 60. The okra plant of the Southern States of America, as universally abounds in the Tenasserim Provinces, and all over the East, as it does in the West Indies.—*Mason.*

(5720) OCOTEA PICHURIM. Species of Ocotea extend from Sylhet to Deyra Dhoon, and ascend to 7000 feet. The fruit, Sassafras nuts or pichurim Beans would be worth examination.—*O'Shaughnessy, p.* 546.

The Massoy Bark,—is a Bark of doubtful origin. It is light, soft to the touch, in long, convex fragments, covered with an epidermis of whitish grey colour, with numerous lichens, internally reddish, tissue rather spongy, brittle, fracture irregular, thickness not surpassing two lines. Taste pungent, bitter, and peppery, odour strongly that of sassafras, with a trace of nutmeg. The Indians attribute tonic properties to this bark; it is rich in essential oil, and proceeds from a lofty and robust tree, very common in New Guinea and in Java. M. Guibourt has detected in this bark the volatile substance previously observed in the Pichurim bean. Fee adds to the preceding articles brief notices of two more species of *Ocotea*, and three of *Litsea*, but their properties are not of material importance.—*O'Shaughnessy, p.* 547.

(5721) OCTOPODA OR OCTOPODIDÆ, a family of Cephalopodous Mollusca to which the genera Octopus, Eledone, Philoxenis and Argonauta belong. It has the following characters: —Animal short, bursiform, ordinarily deprived of fins; head very distinct; 8 sessile arms generally nearly equal, and furnished with simple suckers naked or testaceous, no internal testaceous rudiment, but only two small cartilaginous pieces in some species. Professor Owen, in common with other Zoologists, divides the Octopods into two groups or families, the Testacea and the Nuda. The Testacea consist of the genera Argonauta and Bellerophon.

Argonauta Argo has been from the earliest periods an object of great interest to zoologists, in consequence of the accounts of its sailor-like habits handed down to us from the ancients—we need only refer to the statements of Aristotle, Pliny, Ælian, Oppian, and others—and in consequence of the difference of opinion entertained with regard to the inhabitant of the shell by naturalists; some holding that the Cephalopod found in it was a mere parasite or, even worse, a pirate that had destroyed the legitimate owner and possessed himself of the shell; and others, that the animal was the lawful possessor and original constructor of it. In 1886 Madame Jeannette Power laid before the academy at Catania her 'Osservazione Fisiche sopra il Polpo dell' Argonauta Argo,' in which, after a long and careful course of inquiry, she declared the following results:—1st, that the cephalopodous mollusc usually found therein is the constructor of the shell which it inhabits; 2nd, the clearing

up of the doubts with regard to the first development of its eggs; 3rd, new facts respecting its habits. The following is this lady's description of the cephalopod of the Argonaut:—"It is furnished with eight arms, having on each two rows of suckers; the first two arms are more robust than the others, and should be so, because they serve as masts to support the sails, which, spread out, act before the wind as such. At the base they have on the inferior sides the double row of suckers, like the other six; but from the inferior row, at about an inch from the base in adults, a rather furrowed membrane begins to develop itself, which extends as far as the tip of the arm, and, holding it bent, it can no longer execute the office of a rowing arm, but is employed by the animal as a sail. These sails are so large that, when turned backwards and pressed against the shell, they can entirely cover and protect it. Thus, as far as I can conclude, the true office of these sails is exactly that of keeping themselves applied to the shell at all times, in reserve for the moment when the animal, coming to the surface of the water, removes them, and, spreading them, raises them as sails. In fact, the series of suckers of the sail-arms, when the membrane of the sails is wrapped about the shell, is placed exactly over the keel of it in such a manner that each sucker corresponds to each point in which the ribs of the shell terminate, until they reach the two margins of the spiral." Madame Power compares these sails with the two wing-like lobes of the mantle of *Cypræa* not only from the manner in which they cover the shell, but because she has reason to believe that the formation of the shell is the result of a transudation from the membrane of the sails, the corrugations of which, in secreting the calcareous matter, may be the cause of the ribbed form of the shell. Captain Philip Parker King, R. N., during his well-known voyage, met with some specimens of *Argonauta* in a rather curious way; and though he expresses his opinion with much modesty, it is plain what the inclination of that opinion was. "On our passage from Santos to St. Catherine's, in lat 28° south, we caught," says Captain King, "a Dolphin (*Coryphæna*), the maw of which I found filled with shells of *Argonauta tuberculosa*, [*A. rufa* of Owen] and all containing the *Octopus Ocythoe* that has been always found as its inhabitant. Most of the specimens were crushed by the narrow passage into the stomach, but the smaller ones were quite perfect, and had been so recently swallowed that I was enabled to preserve several of various sizes containing the animal. To some of them was attached tenidus of eggs, which was deposited between the animal and the spire. The shells varied in size from two-thirds of an inch to two and a half inches in length; each contained an *Octopus*, the bulk and shape of which were so completely adapted to that of the shell, that it seemed as if the shell increased with the animal's growth. When so many learned naturalists have differed so materially as to the character of the inhabitants of the *Argonauta*, it would be presumption in me to express an opinion; I therefore merely mention the fact, and state that in no specimen did there appear to be any connection between the animal and the shell." ('Voyages of the Adventure and Beagle,' vol. i. p. 106.) We had an opportunity of examining the specimens above alluded to soon after Captain King's return, and they bore out in every particular the description given by him. Several species are already known; and the specific characters rest in great measure upon the tuberculosities and rib-like elevations on the outside of the shell and on the breadth of the keel. The absence or presence of projecting pointed processes at the sides of the aperture near the spiral part cannot safely be relied on as a specific character: we possessed both broad-keeled and narrow-keeled specimens (now in the British Museum), in which the projecting process was present on one side of the shell and absent on the other. They are inhabitants of the seas of warm latitudes, both littoral and pelagic.

Eledone (Aristotle; Leach).—Arms provided with a single series of sessile acetabula.

E. ventricosa (*Octopus ventricosus*, Grant). Body short, round, the eight arms connected at their base by a membrane.

Octopus Lam., Πολύπους Antiq; and Leach).—Arms provided with a double alternate series of sessile acetabula.

O. vulgaris (*Sepia octopodia* Linn.; *Sepia octopus*, Gmel. Body short and ovoid, the eight arms connected at their base by a wide membrane.—*Eng. Cyc.*

(5722) OCYMUM, a genus of Labiate Plants remarkable for the fragrance of their leaves, which are used as an ingredient in savoury dishes, on which account some of the species have from time immemorial been objects of very general cultivation. In English gardens they are called Basils, a corruption of Basilica, the name given to common Basil by the monkish writers upon plants, in allusion to its regal qualities.—*Eng. Cyc.*

(5723) OCIMUM ALBUM. Linn. White basil; Country tea.

Cunjam koray, Tam. | Kooka tolasie, Tel.
Suffaid Toolsee, Duk. | Viswa tulasi, Sans.
Badrooge abeaz, Arab.

A shrub about a foot high, leaves have a most pleasant aromatic taste and smell. The juice is given to children in colds to the extent of a teaspoonful twice daily. The dried leaves are used as a substitute for tea.—*O'Shaughnessy, p. 593. Ainslie p. 283.* White Basil is chiefly grown in native gardens.—*Riddell.*

(5724) OCYMUM BASILICUM. Linn., Sweet bazil.

Tirnoot patchie veria, Tam. | Dehan siab, Pers. | Kalee tulsee, Hind.
Subze ke beenge Duk. | Manjirika, Sans.
Vepoolpatsa vittiloo Tel.

Common Basil, has many varieties, differing in their size, in the form and colour of their leaves, and in minor particulars: in their qualities they are nearly alike. This species is found wild in the hotter parts of the East Indies, where it is a perennial, with a woody root; but in English Gardens it is treated as a tender annual, being raised in the spring in a hot-bed, and turned into a warm border when the summer is so far advanced that there is no longer any danger from frost, which is instantly fatal to such plants. Besides this Mr Bentham enumerates 43 other species ('Labiatarum Genera et Species'), one of which, the *O. viride*, is used as a febrifuge in Sierra Leone. The genus is readily known by its calyx being bent downwards when the fruit is ripe, and then appearing covered as it were by a very large ovate dorsal lobe, and by the stamens being declinate.—*Eng. Cyc.* The small seeds are deemed cooling and mucilaginous, and consequently given in gonorrhœa, ardor urinæ, and affections of the kidneys.—*O'Shaughnessy, p.* 492. Common sweet basil is not rare, in gardens, but not met with indigenous in Tenasserim.—*Mason.*

(5725) OCYMUM GRATISSIMUM, Strong scented Basil.

Ram Toolsi, Hind.

Cultivated near temples.—*Gen. Med. Top. page* 200.

(5726) OCYMUM HIRSUTUM.

Koolimitan, Tam.

Whole plant slightly aromatic, prescribed by the Hindoos in decoction in the bowel complaints of teething children.—O'*Shaughnessy, p.* 493.

(5727) OCYMUM PILOSUM. Hairy Basil.

Habac, Arabic. | Babai Babooi Toolsee, Hind.
Rihan and Nazboo, Pers.

Common in Upper India. Very common as a weed over all Rajwarra. The green leaves have a delicious smell, exactly like verbena, the seeds are exceedingly mucilagenous and sometimes used as a demulcent. The dried plant prevents bugs approaching beds &c.—*Genl. Med. Top. p.* 200. Seeds aromatic, used by women to relieve after-pains.—O'*Shaughnessy, page* 493.

(5728) OCYMUM SANCTUM, Holy Basil.

Kala Toolsi, Hind.

Cultivated near temples. *Genl. Med. Top. p.* 200.

Tolasee Root.

Tolasee vayer munnie, Tan. | Toolsike munkeh, Duk.
Toolsi ke jur, Duk | Toolasee vayr, tam.

Tolasee is well known to be a plant sacred to Vishnoo and to be held in the highest veneration by all his followers. The root of it is made into beads and worn round the necks and arms of the Vishnoo Brahmins, and Taders. A very handsome bead is sometimes made by polishing the Betel nut called in Tamool Paak munnie.—*Ains. Mat. Med. p.* 443.) The root is given in decoction in fevers, half a tea-cupful twice daily. In Hindoostanee and Bengalee the plant is called kala toolsee, in Sanscrit *Arjaka* and *Paruasa*, (Nalla tirfava, *Rheede.*) The Brahmins regard it as sacred to Vishnu, and use it in their funeral ceremonies. The Malays also strew it over the graves of their dead.—*O'Shaughnessy, page* 493. In the Dekhan Ocymum Sanctum is grown in almost every native garden, and is used for various purposes by Europeans, for flavouring sauces, wine or vinegar.—*Riddell.* Ocymum Sanctum or Holy Basil, is the basil tuft so often seen about the temples of Hindus, where it.

——"waves
Its fragrant blossoms o'er their graves."

It has been so generally introduced in Tenasserim that is not less common in the neighbourhood of Caren houses.—*Mason.*

(5729) OCYMUM VILLOSUM. Woolly Basil.

Sufail, Toolsee, Hind. | Toolasi, Tam.

Cultivated in gardens and near temples.—*Genl. Med. Top. p.* 199. An aromatic herb, leaves used for seasonings, of easy cultivation. In all Courts of Justice, the Hindoos are sworn by these leaves, which are placed on the palm of the hand by a Bramin, who repeats the prescribed oath, and at the termination, they are masticated and swallowed. A good number of the species of this genus are used in cookery.—*Jaffrey.*

(5730) OCYPODIDÆ or OCYPODIANS (Milne-Edwards), a tribe of Brachyurous *Crustacea*, placed by Mr. Milne-Edwards between his Pinnotherians and Gonoplacians. The Ocypodians, as their name implies, are very swift runners, living nearly always on the strand, where they dig holes for themselves. M. Milne-Edwards, who remarks that this small and very natural group is closely allied to the genera *Doto* and *Myctoris* among the Pinnotherians, thus divides the tribe :—

Tribe of Ocypodians.	Cornea transparent, very large, ovail, occupying at least the half of the length of the ocular peduncles, and commencing very near the base of those stems.	Ocypoda.
	Cornea transparent very small, rounded, not occupying the fourth part of the length of the ocular peduncle, and only commencing close to its extremity.	Gelasimus.

Ocypoda (Fabricius). Carapace rhomboidal or even nearly square, as large behind as before. So rapid are the *Ocypodæ* in their motions that those who have observed these animals in their native haunts declare that they run so fast that a man can hardly overtake them. They hollow out holes for themselves in the sand of the sea-bank, and remain shut up in their burrows throughout the winter. They are found in warm climates of both hemispheres. M. Milne-Edwards records seven recent species.

Oils are generally divided into two primary groups, "Fixed" and "Volatile," the former class being again subdivided into drying, greasy, and solid oils. The value of oil as an article of commerce and its numerous uses in candle and soap-making, wool-dressing, food and medicine, as well as its importance as a lubricating agent, are well known. The following table compiled from the official reports of the Madras Custom House will show the quantity and value of all the oils exported from the Presidency.

	1852-53.		1851-52.		1850-51.

from the Madras Territories to the United Kingdom, 7—46 to 1852—53.

Maldive Islands, Mauritius, New South [illegible] and the Straits, Travancore.

[illegible] acid, [illegible] glycerine pro- [illegible] *acroleine*. These [illegible], with the nature of the oil.

[illegible] passing the vapour of fats or oils slowly through a red-hot tube similar effects are produced together with a considerable quantity of hydrocarbons in a liquid, vaporous and gaseous form. Oil-gas is produced by a similar action. What is called *oil of brick* or *philosopher's oil* is prepared by soaking bricks in oil and distilling the oil from them at a red heat in an iron alembic. The recently expressed fixed oils are not much affected by the oxygen of the air: but by continued exposure to light and air, they absorb oxygen rapidly, and give out carbonic acid and hydrogen;—this action may even be so energetic as to produce ignition, especially when the oil exposes innumerable points to the oxygen: as when it is absorbed by porous substances, cotton, tow and cloths used in lubricating machinery, and then thrown into a corner in a heap. There can be no doubt that steamboats, factories, and other places have been set on fire in this way. What are called *drying oils*, such as nut-oil, poppyseed oil, linseed and some others, seem to undergo this kind of oxidation: when exposed in thin layers to the air they dry into a kind of resinous varnish, a process which is greatly accelerated by the addition of a very small quantity of oxide of lead. The *greasy oils*, on the contrary, do not dry, but become rancid by a similar exposure. The purity of the fixed oils may be determined approximatively, and the admixture of cheaper oils detected, 1, by observing the peculiar odour of the oil when gently heated by a spirit lamp in a small porcelain or platinum capsule. The odour evolved will resemble that of the plant or animal from which it was obtained. In this way linseed oil, whale oil, train oil, or rape oil may be detected

[illegible] the
[illegible] fats
[illegible] rogen
[illegible] aute por-
[illegible] adhering impuri-
[illegible] table shows the relative
[illegible] ons of the three elements in 100 parts
of each of the oils named:—

	Carbon	Hydrogen.	Oxygen.
Olive	77·21	13·36	9·43
Almond	77·40	11·48	10·82
Linseed	76·01	11·35	12·62
Nut	79·77	10·57	9·12
Castor	74·17	11·03	14·78
Whale	76·13	12·40	11·50
[illegible]	78·91	10·97	10·12
[illegible]	79·93	11·14	9·75
[illegible]	[illegible]	11·70	9·30
[illegible]	[illegible]	17·60	16·80

Fats and oil are colourless or of a slight yellow tint: they may be bleached by prolonged exposure to light: they are mostly without smell or taste, but the presence of certain volatile acids imparts peculiar odours to some of them; thus butter contains *butyric* and other *acids*; goat's fat *hircic acid*; whale oil *phocenic acid*, &c. The specific gravity of fats is less than that of water; but it varies greatly with their temperature. Thus common hog's lard at 60°, has a sp. gr. of 0·938: at 122° or in a fluid state, it is 0.892; at 152° it is 0·881, and at 200° it is 0·863.

Gelasimus—Carapace much wider than that of *Ocypoda*, more convex, and much narrower backwards. Stomachal region very small, and genital region generally very large. It inhabits the warm countries in both hemispheres. The *Gelasimi* live in holes near the edge of the sea, in pairs, and the great claw of the males is used to stop the entrance of the hole. The species are numerous.

G. Mariomis. Length about 8 lines; width about an inch, French. It is a native of Manilla.

(5731) ODAY OIL, of Cochin, is extracted from a creeper of that name and given to cattle when much worked. It sells at 8 annas a quart. It was sent to the Exhibition of 1851.

(5732) ODINA PUMATA.

Woodiah wood, ENG.	Æaythya marum, TAM. —*M. C. C.*

(5733) ODINA WOODIAR. Terebinthaceæ, Icon. 60.

Awny curry wood, ENG	Juvula, SANS.
Annai karai marum, Oaddy marum, TAM.	Jawul, BENG.
Goompana kurra, TEL.	Kushmulla kimul, Ajasringha, HIND

A very large tree, a native of most mountainous parts of the coast, it is also frequently found in a cultivated state, it grows readily from cuttings which appears the chief motive for employing it, for it is without leaves from the beginning of the year till May or June, and yields no shade in the months when most required. The wood of old trees is close grained of a deep reddish Mahogany colour towards the centre, the coloured part is useful for many purposes. The wood is difficult to season, but when well seasoned, the central reddish portion is useful for many purposes.—*Rhode, M. S. S.* Wight No. 5. From wounds in the bark there issues a gum which when dry is much like pieces of dry glue, but I know of no use it is put to.—*Roxb.* At Maulmain this species of Odina is quite common, and produces a valuable wood. It is called also ooday and generally supposed a very useless tree. The wood is very difficult to season, requiring to be kept, even in planks 2 or 3 years, but once well seasoned it is a close grained beautiful wood well adapted for cabinet making purposes. The gum resin which exudes from the bark, in upper India is called *Jingum* and *Kineh ke-goond.* Dr. Ainslie gives the latter as the synonyme of galbanum.—*O'Shaughnessy, page* 276. Odina Wodier bark is full of fibrous material.

(5734) ODRE, the Tamil name of a Ceylon tree which grows to fourteen inches in diameter, and ten feet in height. It is used by the native carpenters for palanquins and coach work.

(5735) ŒNOTHERA, a genus of Plants belonging to the natural order *Onagrariæ*, or *Onagraceæ*. It has a 4-cleft calyx; 4 petals; a filiform style, with a clavate or cruciform stigma; linear capsules of 4 cells, with 4 valves; and numerous seeds.—*Eng. Cyc.*

(5736) ŒNOTHERA ACAULIS. Evening Primrose. The yellow and white flowering kinds are easily cultivated by seed, in any good garden soil, and will continue during the hot weather to blossom.—*Riddell.*

(5737) ŒNOTHERA BIENNIS, Evening Primrose, has ovate-lanceolate flat toothed leaves; a rough hairy stem; petals longer than the stamens, and about half as long as the tube of the calyx; the flowers are large, numerous, and of a bright yellow-colour. It abounds on the Lancashire coast, and covers several acres of ground near Woodbridge, Suffolk. The roots are eatable, and were formerly taken after dinner to flavour wine, as olives now are; therefore the generic name was changed from *Onagra*, the Ass-Food, to *Œnothera*, the Wine-Trap. This plant was once cultivated for the sake of its tubers, which might in some measure have stood instead of the potato, had they not been superseded by the introduction of the latter. This is the only British species of the genus. There are 85 species enumerated by Don, growing chiefly in North America. They are handsome border-flowers, and deserve to be cultivated, but are not valuable on account of any properties they possess. —*Eng. Cyc.* There are between 70 and 80 species and varieties of this genus, raised from seeds, cuttings, and layers during the rains, will grow in any good garden soil, succeeds best in flower beds, requires plenty of water during the hot months —*Jaffrey.*

(5738) OETHRA (Leach), a genus of Brachyurous *Crustacea*, placed by M. Milne-Edwards as the representive of his first division (Canceriens Cryptopodes) of his tribe Cancerians; and indeed his Cryptopod Cancerians are composed of this genus solely. It is found in East Indian and African Seas.

Oethra seruposa may be taken as an example. Its length is 2 to 3 inches. Colour grayish. It is found near the Island of Mauritius, and in the Indian Archipelago.—*Eng. Cyc.*

(5739) OGECERAS MAJUS.

Hulsi, BENG.

A small tree, a native of the Delta of the Ganges, and such other places as are overflowed at spring tides. Flowering time the hot season.

(5740) OIL.

Huile, FR.	Roghun, PERS.
Oel, GER.	Maslo, RUS.
Teil, GUZ. HIND.	Aciete, SP.
Olie, IT.	Yennai, TAL.
Oleum, LAT.	Noona. TEL.

This term is applied to designate a number of unctuous liquids, expressed or distilled from certain vegetable and animal matters. The oils which form the chief exports from different parts of India to England, France, the Mauritius, &c., are Cocoanut, Jingelly or Sweet Oil, Ground nut, Mustard, Rape, Sandalwood, Roosa or Grass Oil, and Fish Oil.—*Faulkner.*

Oils are generally divided into two primary groups, "Fixed" and "Volatile," the former class being again subdivided into drying, greasy, and solid oils. The value of oil as an article of commerce and its numerous uses in candle and soap-making, wool-dressing, food and medicine, as well as its importance as a lubricating agent, are well known. The following table compiled from the official reports of the Madras Custom House will show the quantity and value of all the oils exported from the Presidency.

Comparative Statement of the Gross Quantity of Oils and Oilseeds Exported from the Madras Territories to the United Kingdom, Foreign Ports and Home Ports, for the years 1847—48 *to* 1852—53.

In addition to the above, about 300,000 lbs. of Wax and Wax Candles, are yearly exported.

These exports are sent to the United Kingdom, America, Arabia, Persian Gulf, Cape of Good Hope, Ceylon, China, France, Maldive Islands, Mauritius, New South Wales, Pegu, West Coast of Sumatra, West Indies, Bengal, Bombay, Concan, Cutch, Goa, Guzerat, French (Indian) Ports, Scinde, Malacca and the Straits, Travancore.

OILS.

Oils are substances of organic origin, and are found in both the animal and vegetable kingdoms. They are divided into Fixed and Volatile. The latter are principally products of the vegetable kingdom. The Fixed Oils are composed of carbon, hydrogen, and oxygen. Their general formula is C_{11}, H_{10}, O. They are liquid or solid according to the manner in which their elements are disposed. Most of them are composed of two compounds, a liquid called Olein, and a solid called Margarin, or another called Stearin. According as these solid substances abound in oils, they are liquid or solid at the ordinary temperatures of our atmosphere. Fixed Oil is found in the fat or adipose tissue of animals. Fixed Oil is found amongst plants principally in their seeds. In some cases as in the Olive [OLEA] it is yielded by the fruit. Some families of plants especially abound in oil. Thus among the *Cruciferæ* we have Mustard, Rape, and Colza seed oil, with other species cultivated in Europe, India, and Japan, of which some have of late years been imported into England. Several of the family of *Compositæ* secrete oil in qantities large enough to render it desirable to cultivate them for this purpose alone, as the sunflower and Jerusalem artichoke, also some species of *Carthamus*, or Bastard Saffron, and also the *Verbesina sativa* of India, now known to be identical with the Abyssinian *Guzotia oleifera*, and of which the oil is known in commerce by the name of hutsyelloo oil. So *Madia sativa* yields madi oil, and its seeds are said to be more abundant in oil than any plant introduced into Europe. Most of the *Cucurbitaceæ* also, as the Melon, Gourd, Cucumber, and the numerous varieties, cultivated especially in India, contain a large proportion of oil, which is expressed in the East, as it formerly was in Europe. The *Rosaceæ* also store up a large proportion of oil in the kernels of their fruit, as in the Almond, which is particularly valued: so also that of the Apricot, as well as that of the Briancon Apricot, and other species of *Prunus*. In the Himalayas, oil is also expressed from the Apricot kernel, and has been sent to this country of a fine quality. Among the *Amentaceæ* we have also several species which yield oil of good quality, and in sufficient quantity, to repay the expense of expression, as Nut oil, obtained from the Hazel; Beech-Nut oil, from *Fagus sylvatica*; with these may be mentioned Walnut oil, from *Juglans regia*. Besides these, Poppy oil, Ben-Nut oil (*Hyperanthera*), Ground-nut oil (*Arachis*), Physic-nut oil (*Jatropha*), are well known. So the cotton-seed yields oil, which is also the case with the seeds of the tea-plants, especially of the species called *Thea oleifera* and some of the Camellias. Two species of *Bassia*, *B. longifolia* and *B. latifolia*, both yield oil; another species, *B. butyracea*, yields a vegetable butter, and is commonly known as the Ghee, or Butter-Tree of Almora. [BASSIA]. The native name of this tree is Choonee, and Mr. Traill describes it as not being found in Kemaon, but in the adjoining Goorkha province of Dotee.—*Eng. Cyc.* Few cultivators says Simmonds are probably aware of the great importance of oil to Britain, and the number of purposes for which it is employed in the arts and manufactures. It is extensively used for candle and soap making, for burning in lamps, for diminishing friction in machinery of all kinds, and especially for locomotives,—in wool-dressing, in the manufacture of paints and varnishes as an article of food, for medicinal purposes, &c. So important are vegetable oils deemed that the Society of Arts, in its prize list for 1851, offered gold medals for the importation or introduction into this country of any new plants or trees from China, India, or elsewhere, producing oils or fatty substances, such as can be used as food, or are applicable to manufacturing purposes; and also to the person who shall manufacture and import the finest specimen of oil, not less than ten gallons, the produce of olives grown in any British colony in Africa or Australasia. The time of burning of equal quantities of the following oils has been found to be—

	Hours.		Hours.
Oil of poppy.	14	Gold of pleasure (*Camelina sativa*)	9½
,, sunflower.	13	,, olives	9
,, rape	11	,, hemp seed	8
,, mustard	11½	,, tallow	10½
,, flax seed	10		

FOREIGN VEGETABLE OILS IMPORTED.

	1821.	1845.	1850.
	tuns.	tuns.	tuns.
Coco-nut oil	- -	2,148	98,040
Olive oil	1900	12315	20,783
Palm oil	3,200	25,285	448,589 cwts
Rape-seed oil	800	3,973	—
Linseed oil	10,500	38 634	- -
	16,400	82,355	
Fish oils	32 356	22,626	21,328

The total quantity of all kinds of wool annually consumed in England and Wales, in 1843, was estimated at 801,566 packs. Now five gallons of olive, rape-seed or other oils, being used in the preparation of every pack of wool for cloth (independent of the quantity used in soap, applicable to the woollen manufactures), it follows that five gallons in 801,566 packs are equal to 4,007,830 gallons, or 15,904 tuns and adding for olive or sperm oil used in machinery, 1-11th of the whole, 1,446 tuns, the total quantity consumed is 17,350 tuns. -(" Enderby on the South Whale Fishery.")—*Simmonds*. Oils and fats may be liquid or solid, but they are easily fusible, and when brought in contact

with paper they make a greasy mark, and render the paper translucent. The fixed oils occur both in vegetables and animals. In the former they occur chiefly in the cellular structure of the seeds, and are supposed by their oxidation or slow combustion to supply the heat necessary to germination. In animals they are deposited chiefly in the cellular membrane. The oils may be of very different consistence even in the same plant or animal: varying from a thin oil, such as almond or spermaceti oil, to solid lard or suet. The vegetable oils are usually obtained from the previously ground or bruised seed by pressure, in some cases assisted by heat. In animals the adipose cells are broken up on the application of heat by the liquefaction and expansion of the fat, which runs out or collects on the surface of the water in which it is. The constitution of fats is stated under CANDLE, to which we must refer. They are compounds of *stearic*, *margaric*, and *oleic* acids, with a base termed *glycerine*, and the *stearate*, the *margarate* and the *oleate* of glycerine are respectively termed *stearine*, *margarine*, and *elaine*. Fat depends for its consistence upon the proportions in which these substances occur: in the solid fats stearine or margarine prevails, and in the liquid oils elain. The ultimate analysis of fats and oils reduces them all to carbon, hydrogen and oxygen. Some of them yield minute portions of nitrogen, the result of adhering impurities. The following table shows the relative proportions of the three elements in 100 parts of each of the oils named:—

	Carbon	Hydrogen.	Oxygen
Olive	77·21	13·36	9·43
Almond	77·40	11·48	10·82
Linseed	76·01	11·35	12·62
Nut	79·77	10·57	9·12
Castor	71·17	11·03	14·78
Whale	76·13	12·49	11·50
Spermaceti	78·91	10·97	10·12
Hog's lard	79·09	11·14	9·75
Suet	78·99	11·70	9·30
Butter	65·60	17·60	16·80

Fats and oil are colourless or of a slight yellow tint: they may be bleached by prolonged exposure to light: they are mostly without smell or taste, but the presence of certain volatile acids imparts peculiar odours to some of them; thus butter contains *butyric* and other *acids*; goat's fat *hircic acid*; whale oil *phocenic acid*, *&c.* The specific gravity of fats is less than that of water; but it varies greatly with their temperature. Thus common hog's lard at 60°, has a sp. gr. of 0·938: at 122° or in a fluid state, it is 0.892; at 152° it is 0 881, and at 200° it is 0·863.

	At 53°.	At 75°.	At 122°.	At 200°.
Nut oil	0 928	0·919		0 871
Almond oil	0 920			0 863
Linseed oil	0 939	0·930	0·921	0·881
Castor oil	0·970	0 957		0 908
Olive oil	0 9 9	0·911	0·893	0 862

The oils may be raised to a high temperature without decomposition; but at certain temperatures they deepen in colour, exhale vapour, and between 500° and 600° undergo decomposition. Hence they cannot be distilled in the ordinary way without being decomposed. The oils cannot properly be said to have any *boiling points*, for when they appear to be in a state of ebullition their glycerine is undergoing decomposition; the fatty acids are either volatilized or form new volatile products; carburetted hydrogen and carbonic acid are evolved, and carbon is left behind. During the distillation the oleic acid is partly converted into sebacic acid, and the stearic into margaric acid, while the decomposition of the glycerine produces an acrid vapour termed *acroleine*. These effects vary, however, with the nature of the oil. On passing the vapour of fats or oils slowly through a red-hot tube similar effects are produced together with a considerable quantity of hydrocarbons in a liquid, vaporous and gaseous form. Oil-gas is produced by a similar action. What is called *oil of brick* or *philosopher's oil* is prepared by soaking bricks in oil and distilling the oil from them at a red heat in an iron alembic. The recently expressed fixed oils are not much affected by the oxygen of the air: but by continued exposure to light and air, they absorb oxygen rapidly, and give out carbonic acid and hydrogen; this action may even be so energetic as to produce ignition, especially where the oil exposes immunerable points to the oxygen: as when it is absorbed by porous substances, cotton, tow and cloths used in lubricating machinery, and then thrown into a corner in a heap. There can be no doubt that steamboats, factories, and other places have been set on fire in this way. What are called *drying oils*, such as nut-oil, poppyseed oil, linseed and some others, seem to undergo this kind of oxidation: when exposed in thin layers to the air they dry into a kind of resinous varnish, a process which is greatly accelerated by the addition of a very small quantity of oxide of lead. The *greasy oils*, on the contrary, do not dry, but become rancid by a similar exposure. The purity of the fixed oils may be determined approximatively, and the admixture of cheaper oils detected, 1, by observing the peculiar odour of the oil when gently heated by a spirit lamp in a small porcelain or platinum capsule. The odour evolved will resemble that of the plant or animal from which it was obtained. In this way linseed oil, whale oil, train oil, or rape oil may be detected

even when used to adulterate another oil. The test, however, is not always a safe one, for the odour of cold drawn oil may differ from the same oil expressed under the influence of heat. Olive oil has a different odour if grown at different places. 2. By mixing concentrated sulphuric acid with oil, (1 or 2 parts acid to 100 oil) the temperature rises and the mixture becomes coloured. If a plate of white glass be placed on a sheet of white paper, and 10 or 15 drops of oil be placed on the glass and a small drop of acid added, a colour will be produced which varies with the oil employed. With *rape oil* a greenish blue ring forms at a certain distance from the acid, while towards the centre light yellow-brown streaks may be observed. In *train oil*, from the whale or stock-fish, a peculiar motion begins at the centre and extends to the outside: a red colour appears and becomes more vivid: in 10 or 15 minutes the margin assumes a violet tinge which in 2 hours is uniform throughout. *Olive oil* instantly becomes pale yellow, and afterwards yellowish green. In *linseed oil* a beautiful dark brownish red web is formed, gradually changing into brownish black. *Tallow oil* or oleic acid becomes brown. "It seldom occurs that a better oil is used to adulterate an inferior one. Oil of almonds, olives, and codfish-oil, will, therefore, never be used for adulterating rape-oil, but probably train or perhaps linsed oil, and sometimes poppy oil. If we are led, therefore, by the odour to infer an adulteration,—for instance by train oil, which occurs the most frequently—it is only necessary to place from 10 to 15 drops of rape oil, the purity of which is undoubted, together with as much train oil, and an equal quantity of the oil whose purity is suspected, and to add to each of them a small drop of sulphuric acid. From the colour produced an inference may be drawn as to the purity of the oil, and by the difference of tinges from the vivid red of the train oil, and the bluish green of rape oil, the extent of adulteration may be detected." This plan is due to Mr. Heidenreich of Strasburg, and is quoted in full in Dr. Normandy's Commercial Hand-Book of Chemical Analysis, 1850, in which will be found a large amount of information respecting the methods of testing the purity of oils. The purity of oils may also be tested by referring to their densities, which are said not to vary in an appreciable manner if the same oil produced in different years. In Saxony an acrometer or *oleometer* is used, it indicates the specific gravity of oils in such a way that pure rape-seed oil is indicated by 17° to 18°, hemp oil by 30° to 31°. There are various other tests: that by the capillarimeter measures the quantity of oil which falls from a certain sized pear under given circumstances. When oil of almonds or pure olive oil is shaken in a phial its surface remains even; but if mixed with oil of poppies it becomes covered with small air bubbles. When olive oil is surrounded with pounded ice it becomes completely solidified, which is not the case if adulterated with oil of poppies. Olive oil is sometimes adulterated with honey, which may be detected by shaking the oil with hot water, which dissolves the honey, and the oil separates when left at rest. The presence of the fish oil in vegetable oils may be detected by passing through them chlorine, which turns them black. The following is a list of the principal unctuous oils of commerce:—

	Sp. Gr.
1. Linseed oil—*Linum usitatissimum et perenne.* Drying.....	0·9347
2. Nut oil—*Corylus avellana*, and *Juglans regia.* D.....	0·9260
3. Poppy oil—*Papaver somniferum.* D	0·9243
4. Hemp-seed oil—*Cannabis sativa.* D.	0·9279
5. Oil of sesamum—*Sesamum Orientale*, Greasy.....	
6. Olive oil—*Olea Europea.* G	0·9176
7. Almond oil—*Amygdalus communis*, G.....	0·9180
8. Oil of ben—*Guilandina moringa.* G.....	
9. Cucumber oil—*Cucurbita pepo et melapepo.* D.....	0·9231
10. Beech oil—*Fagus sylvatica.* G...	0·9225
11. Oil of mustard—*Sinapis nigra et arvensis.* G.....	0·9160
12. Oil of sunflower—*Helianthus annuus et perennis.* D.....	0·9231
13. Rape-seed oil—*Brassica napus et campestris.* G.....	0·9136
14. Castor oil—*Ricinus communis.* D.	0·9611
15. Tobacco-seed oil—*Nicotiana tabacum et rustica.* D.....	0·9232
16. Plum-kernel oil—*Prunus domestica* G.....	0·9127
17. Grape-seed oil—*Vitis vinifera.* D.	0·9262
18. Butter of cacao—*Theobroma cacao.* G.....	0·8920
19. Cocoa-nut oil—*Cocos nucifera.* G...	
20. Palm oil—*Cocos butyracea.* G.....	0·968
21. Laurel oil—*Laurus nobilis.* G.....	

	Sp. Gr.
22. Ground nut oil—*Arachis hypogæa.* G.	
23. Piney tallow—*Valeria Indica.* G..	0·926
24. Oil of Julienne—*Hesperis matronalis.* D....	0·9281
25. Oil of Camelina—*Myagrum sativa.* D.....	0·9252
26. Oil of weld-seed—*Reseda luteola.* D.	0·9328
27. Oil of garden cresses—*Lepidium sativum.* D.....	0·9240
28. Oil of deadly nightshade—*Atropa belladonna.* D.....	0·9250
29. Cotton-seed oil—*Gossypium Barbadense.* D.....	
30. Colza oil—*Brassica campestris; B. Oleifra* G.....	0·9136
31. Summer rapeseed oil—*Brassica præcox.* G.	0·9139
32. Oil of radish-seed—*Raphanus sativus oleifera.* G.	0·9187
33. Cherry-stone oil.—*Prunus cerasus.* G.	0·9239
34. Apple-seed oil.—*Pyrus malus.* G.	
35. Spindle-tree oil.—*Euonymus Europæus.* G.	0·9380
36. Cornel-berry-tree oil—*Cornus sanguinea.* G.	
37. Oil of the roots of cyper-grass—*Cyperus esculenta.* G.	0.0180
38. Henbane-seed oil—*Hyosciamus niger.* G.	0·9130
39. Horse-chestnut oil—*Æsculus hippocastanum.* G.	0·927
40. Pine top oil.—*Pinus abies.* D.....	0·928

The proportion of oil contained in seeds is often very considerable: linseed contains 20 per cent. of oil.; rape-seed from 35 to 40; castor oil seeds as much as 60 per cent. The oil is usually obtained by means of expression. In Europe, an oil-mill is used for the purpose; but it is desirable first to pass such hard seed as lint or rape between iron rollers, in order to crack the shells. These rollers are of cast-iron, turned truly in a lathe, and their spindles run in brass bushes fixed in an iron frame bolted to the frame work of the mill. These frames have mortises, in which the bushes for the rollers are placed and are adjusted by screws passing through the ends of the iron frames: this allows the rollers to be set at any distance apart, according to the size and hardness of the seed to be crushed. The rollers are sometimes of different sizes, so that different velocities may be given to their surfaces: this enables them to draw the seeds in, and to perform their work more quickly. One of the rollers has on its axis a small spur-weel, which engages a cog-wheel on the main shaft of the mill. Its motion by another pinion to the second roller. By giving to the roller pinions a dissimilar number of teeth, they may be made to revolve with different velocities, which answers the same purpose as making them of different sizes. Above the rollers is a hopper containing the seed, which runs out at an opening in the bottom into a trough or shoe, which is agitated by a piece of wood nailed to it resting on the cogwheel: the shoe thus feeds the rollers with a small quantity of seed at a time, and prevents them from being choked up. A plate of iron attached to the frame on each side presses by its edge against the lower part of the rollers, and scrapes off any adhering seed. The crushed seed falls upon an inclined board, and collects in a heap, from which it is removed to feed the running stones. The arrangement of the rollers resembles that of the crushing mill. The seed broken by the rollers is passed under two vertical mill-stones or *runners*, revolving on a horizontal bed, where it is further bruised and prepared for compressiou. In some places the rollers are not used, but the seed is at once subjected to the action of the runners. Hard and smooth grains are, however, liable to slip away from beneath the running stones, and thus require a much longer time to prepare them for the next process, that of compression. Rollers do their work rapidly, but they require great power to work them. When the seed is sufficiently bruised by either or both of these means, it is collected into hair bags and placed in what is called a *wedge-press* In olive-oil mills a screw-press may be used but the hardness and smoothness of the grains of lint and rape, and the cavities formed by the broken shell which retain the oil, require the exertion of a stronger force. The hair bags containing the crushed seeds are placed between wedges of wood contained within a strong framing. The wedges are then driven down by a heavy *ram* or pestle worked by machinery until the pestle rebounds from them 3 times, when they are judged to be sufficiently tight. The oil thus obtained is of the *best quality*, and is kept distinct from that obtained by the after process. The seeds come out of the bags in the form of flat cakes: these are broken up, and pounded in mortars with

heavy stampers, which reduce the parenchyma of the seed to a fine meal, so that the oil can escape more freely when subjected to a second compression, which is now aided by heat. The pounded seed or meal is heated to the temperature of melting bees'-wax in a pan, and is kept in agitation by a spatula worked by machinery The meal is again put into hair bags and compressed, and the resulting oil is considered to be the *best* of the *second* quality. Another compression produces oil of the *ordinary second quality*. During the heating of the meal a little water is sometimes added; but in Holland this practice is considered to be injurious. The cakes are still fat and soft, and are sold as food for cattle; but the Dutch break them down and stamp them again. The result is an impalpable paste, which is head with a very little water, and kept for some time at the temperature of boiling water, with diligent stirring. It is then subjected to the greatest pressure that has yet been applied, and the result is an oil of the *lowest* quality. The cake is dry and hard like a board, and is used for manure. Some of the small millers in Holland purchase oil-cakes from France and Flanders for the purpose of preparing this inferior oil. —*Tomlinson.*

Native Oil Mills.—The principal native oil mill of India, of which, however, there are some varieties, consists of a simple wooden mortar with revolving pestle. It is in common use; two oxen are harnessed to the geering, which depends from the extremity of the pestle,—a man sits on the top of the mortar, and throws in the seeds that may have got displaced. The mill grinds twice a day; a fresh man and team being employed on each occasion. When sesame oil is to be made, about seventy seers measure, or two and a half bushels of seeds are thrown in; to this ten seers, or two quarts and three-quarters of water, are gradually added; this on the continuance of the grinding, which lasts in all six hours, unites with the fibrous portion of the seeds, and forms a cake, which, when removed, leaves the oil clean and pure at the bottom of the mortar. From this it is taken out by a coco-nut shell cup, on the pestle being withdrawn. Other seed oils are described by Dr. Buchanan, as made almost entirely in the same way as from the sesamum. The exceptions are the castor oil, obtained from either the small or large varieties of *Ricinus*. This, at Seringapatam, is first parched in pots, containing something more than a seer each. It is then beaten in a mortar, and formed into balls; of these from four to sixteen seers are put in an earthenware pot and boiled with an equal quantity of water, for the space of five hours; frequent care being taken to stir the mixture to prevent it from burning. The oil now floats on the surface, and is skimmed off pure. The oil mill made use of at Bombay, and to the northward, at Surat, Cambay, Kurrachee, &c., differs a little from that just described, in having a very strong wooden frame round the mouth of the mortar; on this the man who keeps the seeds in order sits. In Scinde a camel is employed to drive the mill instead of bullocks. Castor oil seed is thrown into the mill like other seeds, as already described; when removed it requires to be boiled for an hour, and then strained through a cloth to free it from the fragments of the seed. It is a curious fact, and illustrative of the imperfect manner in which the oil is separated from the seeds, that while the common pressman only obtained some 26½ per cent, Boussingault, in his laboratory, from the same seeds, actually procured 41 per cent. When the oil cakes are meant for feeding stock, this loss is of little consequence, inasmuch as the oil serves a very good purpose, but when the cake is only intended to be used as a manure, it is a great loss, inasmuch as the oil is of little or no use in adding any food for crops to the soil.—*Simmonds.*

The volatile oils are very numerous in the Vegetable kingdom. They are called volatile on account of the ready manner in which they may be volatilised under the influence of heat. The facility with which they are diffused in the atmosphere renders them easy of detection, and it is to this class of substances that plants owe their peculiar odours. Many of them are employed in perfumery, others are used as stimulants in medicine, and some are poisons. Their composition is much more varied than that of the fixed oils, and to the chemist they offer an exceedingly interesting field of research. Many of them have a constitution analogous to the compounds obtained by chemists from the compound radicals. They are divided by chemists into three groups:—1, those containing only carbon and hydrogen, as oil of turpentine; 2, those containing also oxygen, as oil of cloves; 3, those containing sulphur, as oil of garlic. Many natural orders are characterised by yielding volatile oils. Thus the *Lamiaceæ*, *Myrtaceæ*, and others, embrace species all of which contain volatile oil in their leaves. Many of the *Umbelliferæ* yield a volatile oil in their fruits. The petals are often the seat of these secretions, and especially those most prized as the Rose, the Jasmine, the Heliotrope, and many others.—*Eng. Cyc.* Appended is a table of volatile oils employed in medical practice. They are almost all powerful stimulants and carminatives. A drop or two dissolved in a few minims of spirit, and an ounce of water added, gives an extemporaneous substitute for the distilled water of the plant, and a useful vehicle for many draughts or mixtures. These oils are often added in minute quantities to pill-masses, either to give an agreeable flavour, or counteract their tendency to griping.—*Beng. Phar. page* 379.

TABLE OF VOLATILE OILS.

Classical and English Name of Plant.	Native names.	Part used.	Colour of Oil.	Sp. Gr.	Uses and Remarks.
Pimpinella anisum, common anise, ...	.....	Fruits, ...	Yellow, ...	0.985	Carminative congeals at 50°.
Illicium anisatum, star anise, ...	Badian kutai. ...	Do., ...	Do., ...	Do.	Ditto.
Anthemis nobilis, chamomile, ...	Baboone, ...	Flowers, ...	Deep blue, ..	.....	Tonic, authelmintic.
Lavandula vera, lavender, ...	.....	Do , ...	Yellow, ...	0.877 to 0 905	Fragrant, stimulant.
Ruta graveolens, and other species, rue, ...	Sudab, ...	Do. and herb, ..	Do , ...	.....	Stimulant given in amenorrhœa.
Andropogan Iwaranchusa, ...	Roosa, ...	Grass,... ...	Do., ...	.....	Fragrant and stimulant.
Anethum graveolens, dill, ...					
—— Sowa, ...	Souf, ...	Fruits, ...	Do., ...	0.994	Stimulant in flatulence.
—— Panmori, ...					
Carum carui, carraway, ...	Zeera seeah, ...	Do., ...	Do., ...	.....	Ditto.
—— Nigrum, ...					
Eugenia Pimento, (allspice,)	.....	Do., ...	Do., ...	.....	
Amomum Zingeber, (ginger,)	Ada, ...	Root, ...	Do , ...	.....	Ditto.
Fœniculum officinale, (fennel,)	.....	Fruits, ...	.....	0.997	
Melaleuca cajeputi, (cajeput,)	Kyapooti, ...	Leaves, ...	Green, ...	0.927	
Juniperus communis, (juniper,)	Hoober, ...	Fruits, ...	Do., ...	0.878	Stimulant and diuretic.
Piper Cubeba, (Cubebs,)	Kubab chinee, ...	Do., ...	Yellow, ...	.....	Ditto.
Caryophyllus aromaticus, (clove,) ...	Long, ...	Unripe flowers dried.	Do., ...	1.055	Almost caustic.
Laurus cinnamomum, (cinnamon,)	Darchinee, ...	Bark, ...	Reddish yellow, ...	.....	Ditto.
Juniperus sabina, (savine,)	.....	Tops, ...	Yellow, ...	.....	In amenorrhœa.
Ocymum basilicum, (basil,)	Tulsi, ...	Herb,...	Do., ...	.....	
Rosmarinus officinalis, (rosemary,) ...	.....	Tops, ...	Do., ...	0.934	Carminative.
Moringa pterygosperma, (sohunjuna,) ..	Sohunjuna, ...	Roots,...	Do., ...	.....	Vesicatory.
Mentha piperita, (peppermint,)	.....	Herb, ...	Do., ...	0.920	Ditto, much used in cholera.
Mentha pulegium, (pennyroyal,)	.....	Do., ...	Do., ...	.....	Ditto, Stimulant.
Mentha viridis, (spearmint,)	Pudina, ...	Do., ...	Do., ...	.....	Ditto.
Amomum cardamomum, (cardamom,) ...	Elachee, ...	Fruits, ...	Do., ...	.....	
Origanum majorana, (marjoram,) ...	.....	Herb, ...	Do., ...	.....	Ditto.
Sassafras officinale,* (sassafras.)	.....	Bruised root, ...	Do., or colorless, ..	1.094	Fragrant and diuretic.

* A beautiful oil has been obtained from the Nipal sassafras.

Beng. Phar. p. 380.

Fixed oils are found in the cells and intercellular spaces of the fruit, leaves and other parts of plants. Some of these are drying oils, as linseed oil, from *Linum usitatissimum*; some are fat oils, as that from olives (fruit of *Olea sativa* or *Europæa*); whilst others are solid, as palm oil. The solid oils, butters or fats procured from plants have been described under the head. *Butter*, to which we refer, merely mentioning here that the chief are, butter of cacao, from *Theobroma cacao*; of cinnamon, from *Cinnamomum verum*; of nutmeg, from *Myristica moschata*; of cocoanut, from *Cocos nucifera*; of laurel, from *Laurus nobilis*; of palm oil, from *Elais guianiensis*; Shea butter, from *Bassia Parkii*; Galam butter, or Ghee, from *Bassia butyracea*; and vegetable tallow, from *Stillingia sebifera* in China, from *Vateria indica* in Canara and China, and from *Pentadesma butyracea* in Sierra Leone, and from the almond. These oils contain a large amount of stearine, and are used as substitutes for fat. Some of them are imported in large quantities, and enter into the composition of soap, candles, &c.—Castor oil, from the seeds of *Ricinus communis*, differs from other fixed oils in its composition. Decandolle states the following as the quantity of oil obtained from various seeds :—

	Per cent. in weight.
Hazel-nut, ...	60
Garden cress, ...	57
Olive, ...	50
Walnut, ...	50
Poppy (*Papaver somniferum*)	48
Almond, ...	46
Caper-spurge (*Euphorbia Lathyris*) ..	41
Colza (*Brassica oleracea*), ...	39
White mustard (*Sinapis alba*), ...	36
Tobacco, ...	34
Plum, ...	33
Woad	30
Hemp, ...	25
Flax, ...	22
Sunflower, ...	15
Buckwheat, ...	14
Grapes, ...	12

The following table, quoted from Boussingault, shows the results of some experiments made by M. Gauzac, of Dagny :—

	Seed produced per acre.			Oil obtained per acre in lbs.		Oil per cent.	Cake per cent.
	cwts	qrs.	lbs	lbs	ozs.		
Colewort	19	0	15	875	4	40	54
Rocket	15	1	8	320	8	18	73
Winter rape...	16	2	18	611	6	33	62
Swedish turnips	15	1	25	595	8	33	62
Curled colewort	16	2	18	641	6	38	62
Turnip cabbage	13	3	19	565	4	33	61
Gold of pleasure	17	1	16	545	8	27	72
Sunflower	15	3	14	275	0	15	80
Flax	15	1	25	385	0	22	69
White poppy	10	1	18	560	8	46	52
Hemp	7	3	21	229	0	25	70
Summer rape...	11	3	17	412	5	30	65

Simmonds. In estimating the value of an oil producing plant or tree, the other valuable products which it yields should not be lost sight of. The linseed in addition to its oil produces the scarcely less valuable flax, hemp yields a fibre and an intoxicating resin, safflower, a dye—pinnacotay, a soft inferior gum—poonga, a valuable timber—piney, a resin—gamboge tree, a valuable pigment—mahowa, a spirit distilled from the flowers, &c, &c., whilst in the case of the poppy, the oil is second in importance to the more valuable opium. An excellent epitome of the particular qualities, on which the value of an oil as an article of commerce depends will be found in the accompanying extracts of a letter from G. F. Wilson. Esq. to Sir William Hooker, Royal gardens, Kew : "Every oil, or grease, whether solid or liquid, if not poisonous or acrid, like croton oil, viscid and gummy, like castor oil, or drying, like linseed oil, must be worth in London at least £30 a ton. Among greases solid at above 60° Fahrenheit, the higher the melting point (other things equal), the greater the value; for example, the vegetable tallow of Borneo melting at about 90° Fahrenheit is worth at least £5 a ton more than the cocoanut oil of Ceylon melting at 70°. The effect of the soap duty having been taken off, may probably before long, materially change the relative values of greases; but at present, liquid oils, like the ground nut (*Arachis Hypogea*) are worth more than soft solid oils, like the Bassia butter of India, as they require less manufacturing to fit them for use, the liquid oil after a simple treatment in a cheap apparatus, being fit for burning in lamps, while the soft solid oils being neither hard enough for use in candles, or liquid enough for use in lamps, require to go through a press before they are saleable, except for soap-making. Greases may have particular advantages, such as being little acted upon by the air, and therefore not easily becoming rancid, but these good qualities, can only be ascertained by experiments which your correspondents had perhaps better leave to us." "We have been engaged in some experiments upon oils, for use in medicine, in which it seems provable they will take an im-

portant place; already one vegetable oil has been found to be almost as efficacious as cod liver oil, with the advantages of being less unpleasant and cheaper. On account of this new use, it might be well to collect small quantities of oils, even if they did not obey the conditions mentioned above. The value of oil must depend a little (especially when found in out of the way places) upon the way it is held in its matrix; for example. the oil of the Lumbang-nut (*Aleurites triloba*) can be separated with much less labour and simpler machinery than the cocoanut oil, which requires very great pressure to extract it from the copperah, or dried cocoanut kernel." "Waxes are worth more than greases, on account of their very high melting points; their relative values depend upon colour, transparency, and freedom from resinous matter. Resin may be easily detected by lighting a small piece of the wax; the more smoke, the greater proportion of resin, and therefore less value; the paler and more transparent the wax the better. The most valuable tree wax known, is the beautiful insect wax of China." "A simple way to try an oil nut is to crush it with a stone, and then squeeze it between the finger and thumb; if it contains any considerable quantity of greases, enough will be pressed out to judge of colour, hardness and sweetness; if the nut tastes oily, and yet oil does not come out by this treatment, it is well to dry the kernel before squeezing; and, in the case of nuts containing greases, solid at a high temperature, like that of the *Myristica Sebifera*, it is well also to heat the nut. Where a stearic candle can be got, and is burned down a little, until it has formed a cup, and then extinguished, into this a little of the material to be tried may be placed; after a moment's burning, the candle material with which the wick is saturated is burned out, the new material to be tried, in the cup takes its place, and becomes the material supplying the wick until the cup is emptied, and so can be judged of, or a piece of string dipped in the oil or melted grease makes a very tolerable wick; or simpler still, where the nut is very full of oil if lighted at one end, it will at least show what tendency to smoke there is, and the colour of the light." "Some of the resins ought to come in for candle making, though I believe that they have never been extensively used, except for the commonest sorts of candles, on account of their giving off so much smoke; but as some descriptions smoke less than others, there is a hope that new ones may be found smoking still less: these would then be very serviceable in candle making. The points connected with new greases, &c., that we should be most thankful for information upon, are, the manner of growth, probable expense of collecting, means of transport, and quantity likely to be obtained, with small specimens of the grease, if manufactured, and of the fruit, with both its husk and hard shell, where these exist."

Of vegetable substances of Southern Asia, producing "volatile oils" there is an immense variety, but with the exception of the oils of cassia and cinnamon, roosa and the rose utter, few are of any commercial importance, nor are they prepared in any quantity for consumption in India. Scented oils erroneously termed "volatile" obtained by the repeated distillation of fragrant herbs, &c., over into a receiver containing a portion of any fixed oil, to which the aroma is imparted, are prepared to some extent but chiefly for native use. Sandalwood oil and the large variety of utters, &c., which form the principal part of native perfumery are included in this class.—*M. E. J. R.* The subjoined list will serve to exhibit the richness of the produce of different seeds, of Southern Asia, from which varieties of oil are extracted; it gives the proportion of oil per cent. in weight:—

Black til, (*Verbesena sativa*), ...	46·4
Gingely oil (*Sesamum orientale*), ...	46·7
Ground nuts, *Arachis hypogæa*, ..	45·5
Pounded seeds obtained from the Ponnay-tree (*Calophyllum inophyllum*), a bitter lamp oil, ...	63·7
Karunj seeds, from the *Pongamia glabra*	26·7
Ram till, the seeds of *Guizotia oleifera*,	35
Poppy seeds (*Paparer somniferum*), ...	43 to 58
Silaam, an oil seed from Nepaul, ...	41
Rape seed (*Brassica napus*), ...	33

The foregoing are not all the seeds from which oil is extracted by the natives of Southern Asia. —*Simmonds.* The oil seeds most generally cultivated in India are the castor, gingely, rape, mustard, ground nut, ramtill, linseed, and poppy, but the latter is cultivated for its opium the seed forming a secondary consideration. The following plants grow in a wild state, their fruit being collected and the oil expressed as occasion requires; margosa, ben, brumadundoo, pinnacotty, soap-nut, kurunj, cashew-nut, poovana, piney, neradimootoo, physic-nut, cheeronjee, coorookoopilly, &c. &c. &c.—*Madras Exhibition Juries Reports.* Oil is, in Malay, *minah*, and in Javanese, *langa*, both of them words of extensive currency throughout the Malay and Philippine Archipelagos. The plants from which fatty oils are chiefly extracted are the coco-palm, the ground pea, the sesame, and the palma christi; the first for edible use, and the three last for the lamp. In the islands of the Molucca sea, a fine esculent oil is expressed from the nut of the kanari tree (Canarium commune). Crawfurd is not aware that oil is expressed in any of the islands from cruciform plants, nor is flax reared for this purpose. Animal oils are hardly used in any shape: essential oils are obtained from the clove, the nutmeg, the kayu-puti (Melaleuca cajeput) and in great abundance and cheapness from the Malay camphor-tree (Dryobalanops camphora). —*Crawfurd Dict. page* 307. One hundred and twenty fixed oils are known to be produced

hroughout the Madras Presidency and Burmah. These may be arranged as follows :

Fixed Vegetable oils, including drying, greasy and solid oils,	105
Wood oils,	10
Mineral oil,	1
Animal oils,	4
Total...	120

Of the first class, Coconut, Castor, Ground-nut, Gingely and its variety, Rape, Mustard and Linseed form considerable articles of foreign trade. The first three being exported in the shape of oil, the last two as oil seed, and Gingely, both as an oil and oil seed. In addition to these, the following are consumed to a large extent in India :—Lamp, Ramtill, Kurunj, Pinnacotay, Illoopoo, Piney or Doopada, Margosa or Neem, Physic nut, Brumadundoo, Safflower and Poppy. Of the remainder some are medicinal and some are prepared only in those localities, in which the substances producing them happen to abound in a wild state. The prices of these products vary very considerably, not only in different parts of the Presidency, but even in various towns of the same district. It is therefore difficult, if not altogether impracticable, to fix their respective values, with any degree of certainty ; an increased demand or greater facility of transit moreover considerably affect their present value —*M. E. J. R. Eng. Cyc.* The following list contains the names of the better known oils of Southern Asia.

Oil of sweet flag,	Acorus calamus.
Do. belgaum walnut,	Aleurites triloba.
Do. caju,	Anacardium occidentale.
Do khus-khus, or vetiver,	Anatherum muricatum.
Do. grass, or oil of spike-nard (roosa ka tel),	Andropogon calamus aromaticus.
Do of bishops weed seed,	Anethum sowa.
	Apricot Oil, Choohara and Zind Aloo-ke tel.
Do. ground nut,	Arachis hypogœa.
Do prickly poppy,	Argemone mexicana.
Butter of Ghee tree,	Bassia Butyracea
Do. mawa,	Bassia latifolia.
Do. illoopoo,	Bassia longifolia.
Do. kawan,	Bassia species.
Do. Shanghae,	Brassica chinensis.
Rape seed,	Brassica napus.
Do. pulas,	Butea frondosa,
	Cæsalpina oleosperma,
Do. poon seed,	Calophyllum inophyllum.
Oil hemp seed,	Cannabis sativa.
Do. koosum,	Carthamus tinctorius.
Do. of cloves,	Caryophyllus aromaticus.
Do of cummin,	Cuminum cyminum.
Do. malkungance, or staff tree,	Celastrus paniculata.
Do. cheeronjee,	Chirongia sapida.
Do. of cassia	Cinnamomum species.
Do. of cinnamon,	Cinnamomum zeylanicum.
Do. of lemons,	Citrus limonum.
Do cocoanut,	Cocos nucifera.
Do. of coriander,	Coriandrum sativum.
Do. cucumber seed,	Cucurbita pepo.
Do. melon seed,	Cucumis melo.
Do. pumpkin seed,	Cucurbita maxima.
Do. purging,	Curcas purgans.
Do wood	Dipterocarpus several spec
Agait or Napoota	Didynamia gymnosperma
Do. mijo,	Dolichos soja.
	Dolichos biflorus.
Do. of cardamom,	Ellettaria cardamomum.
Do. Japan,	Erysimum perfoliatum.
Do. of sweet fennel,	Fœniculum dulce.
Do. gamboge butter,	Garcinia pictoria.
	Garcinea purpurea.
Do. bondue nut,	Guilandina bonduc.
Do. ramtil,	Guizotia oleifera
Do. of Ben, Sohunjna,	Hyperanthera Moringa.
Sun flower,	Helianthus Annuus.
Do. glaucous leaved physic nut,	Iatropha glauca.
Do. of star anise,	Illicium anisatum
Do. of jessamine,	Jasminum, (var, sp.)
Do. Chinese,	Kin.
Do. linseed	Linum usitatissimum.
Do of cajeput,	Melaleuca cajuputi.
Do. neem,	Melia azaderach.
Do. of mint,	Mentha piperita.
Do. mimusops	Mimusops elengi.
Do. ben,	Moringa pterygosperma.
Do. nutmeg,	Myristica moschata.
Do. of tobacco,	Nicotiana tabacum.
Do. fennel flower,	Nigella sativa.
Do. of keora	Pandanus odoratissimus.
Do. poppy seed,	Papaver somniferum.
Do. anise,	Pimpinella anisum.
Do. of pepper,	Piper nigrum.
Do. putchapat,	Pogostemon patchouli.
Do kurrunj,	Pongamia glabra.
Do. of (Prinsepia Utilis),	Ricinus Communis.
	Salvadara persica.
Do. castor,	Santalum album.
Do. of sandalwood,	Sapindus emarginatus.
Do poonga,	Sarcostigma kleinii.
Do. of sassafras,	Sassafras officinale
Saul,	Shorea robusta.
Do. shaynecotay	Semecarpus anacardium.
Do. gingelly,	Sesamum indicum.
Do mustard	Sinapis alba.
Chinese tallow tree,	Stillingia sebifera.
Oil pea	Suchaw,
Mustard Oil, of kinds.	
Kalee Surson	
Surson.	
Tira,	Species of Sinapis, &c.
Toria and Kurwa,	
Race,	
Do. fetid sterculia,	Sterculis fœtida.
Do. nux vomica,	Strychnos nux vomica.
Do. wild almond	Terminalia catappa.
Do. portia nut,	Thespesia.
	Theobroma cacao.
Do. croton,	Tiglium officinale,
Do. vegetable tallow,	Vateris indica.
Kuttsella, Black till of Deccan, Kala til-ke-tel,	Verbesina Sativa.
	Vernonia anthelmintica.
	Xylocarpus gr natum. Sy
	Carapa moluccensis.

Madras Exhibition of 1857.

In addition, there are cotton-seed oil used for their lamps, Castor oil and Argemone seed similarly used. Oil obtained from the fruit of *Melia azadirachta*, &c, for medicine and lamps Apricot oil in the Himalayas, sunflower oil, oi

of cucumber-seed for cooking and lamps, oil of colocynth seed, used as lamp oil. The seeds of bastard saffron (*Carthamus tinctorius*) yield oil. Mustard oil, the produce of various species of *Sinapis*, &c. Shanghae oil, from *Brassica chinensis*; Illiepie oil, from *Bassia longifolia*, which is used for frying cakes, &c., in Madras; and Mahwa oil, from another species of the same genus *Bassia latifolia*. Oil is expressed from the seeds of *Cæsalpina oleosperma*, a native of the East. The neem tree seeds afford a very clear or bitter oil, used for burning. Wood oil is a remarkable substance, obtained from several species of *Dipterocarpus*, by simply tapping the tree. The seeds of the *Argemone mexicana*, also contain a bland, nutritious, colorless, fixed oil. The mass from which the seed is expressed is found to be extremely nutritious to cattle. A solid oil, of a pale greenish color, a good deal resembling the oils of the Bassia in character, though rather harder, and approaching more in properties to myrtle wax, was shown at the Great Exhibition, from Singapore. It is supposed to be the produce of the tallow tree of Java, called locally "kawan," probably a species of Bassia. It is very easily bleached; indeed, by exposure to air and light, it becomes perfectly white; if not too costly, it promises to become a valuable oil. According to Mr. Low, there are several varieties of solid oil commonly used in the Islands of the Eastern Archipelago, and obtained from the seeds of different species of *Dipterocarpus*. Piney tallow is obtained from the fruit of the *Valeria indica*, a large and quick-growing tree, abundant in Malabar and Canara. It is a white solid oil, fusible at a temperature of 97 degrees, and makes excellent candles, especially when saponified and distilled in the manner now adopted with palm oil, &c. It has one great advantage over coco-nut oil that the candles made of it do not give out any suffocating acrid vapors when extinguished, as those made with the latter oil, do. An oil is produced from the inner shell of the cashew-nut *Anacardium occidentale* var. *indicum*, in the East. In Japan a kind of butter called *mijo*, is obtained from species of the Dalichos bean (*Dolichos soja*). The kernel of the seeds of the tallow tree of China, *Stillingia sebifera*, an evergreen shrub, contains an oil, which when expressed, consolidates through the cold to the consistence of tallow, and by boiling becomes as hard as bees' wax. The plant also yields a bland oil. A similar fatty product is obtained from a shrub in British Guiana, the *Myristica* (*Virola*) *sebifera*. Oil is obtained in South America from the sand box tree (*Hura crepitans*), and from the *Carapa guianensis*. The seeds of several plants of the cucumber family frequently supply a bland oil, which is used in the East as a lamp oil and for cooking. Among the vegetable oils imported into Ningpo, and other Chinese ports, from Shantong, Leatong, and Teisin, are oil of teuss, obtained from green and dried peas; black oil of the fruit of the tree *kin* (?) and oil from the pea of suchau. A pale brownish yellow oil is obtained from the seeds of *Carthamus tinctorius*, in Bombay, the seeds of which contain about 28 per cent. of oil. Excellent oil is expressed in various parts of India from the seeds of different species of *Sinapis*, especially from the black mustard seed. *S. glauca*, *S. dichotoma*, and *S. juncea* are extensively cultivated in the East for their oil. The *Erysimum perfoliatum* is cultivated in Japan for its oil seeds. A beautiful pale yellow oil is procured from the seeds of the angular-leaved physic nut. *Jatropha curcas*, a shrub which is often employed in the tropics as a fence for enclosures. It is used by the natives in medicine and as a lamp oil. About 700 tons of this oil was imported into Liverpool in 1850 from Lisbon, for the purpose of dressing cloth, burning, &c. An oil called Carab oil is also obtained in the East, from the almonds of *Xylocarpus granatum*, or *Carapa Moluccensis* of Lamarck, which is used by the natives to dress the hair and anoint the skin, so as to keep off insects. Cacao fat, the butter-like substance obtained from the seeds of *Theobroma cacao*, is esteemed as an emollient. The Agaiti, as it is called by the Portuguese, or napoota by the natives and Arabs (*Didynamia gymnosperma* ?), is much cultivated in all Eastern Africa for its oil, which is considered equal to that of olives, and fetches as high a price in the Indian market. The plant, which is as tall and rank as hemp, and equally productive, having numerous pods throughout the stems, is found everywhere in a wild as well as cultivated state. The "Cape Shipping Gazette," of August, 1850, says:—"The attention of the George Agricultural and Horticultural Society having been drawn to the fact that an excellent oil, equal to the olive oil of Italy, can be extracted from the kernel of the fruit known by the name of "T Kou Pijte" and "Pruim Besjee," they have offered a reward of £10 for the best sample, not less than a half sum of this oil—£15 if it shall be adjudged equal to the best oil of Italy. This fact is deserving of notice, as an instance of the advantages which are likely to result from the attention now being devoted to the natural productions of the colony." Cocum oil, or butter, is obtained from the seeds of a kind of Mangosteen (*Garcinia purpurea*), and used in various parts of India to adulterate ghee or butter. It is said to be exported to England for the purpose of mixing with bears' grease in the manufacture of pomatum. It is a white, or pale greenish yellow, solid oil, brittle, or rather friable, having a faint but not unpleasant smell, melting about 94 degrees, and when cooled after fusion remaining liquid to 75 degrees. An excellent solid oil, of a bright green color, is obtained from Bombay,

having a consistence intermediate between that of tallow and wax, fusible at about 95 degrees, and easily bleached; it has a peculiar and somewhat aromatic odour. There is some uncertainty as to the plant from which it is obtained. It was referred to the *Salvadora persica*, and to the *Vernonia Anthelmintica* a plant common in Guzerat and the Concan Ghats. A pale yellow clear oil is obtained from the seed of *Dolichos bifforus* (?). Oil is also expressed in India from the seed of the *Argemone mexicana*, which is used for lamps and in medicine; and from the seeds of the cashew nut (*Anacardium occidentale*), from *Sapindus emarginatus*, and the country walnut (*Aleurites triloba.*) The fruit of the *Chirongia sapida*, (or *Buchanania latifolia*,) yields oil. From the seeds of the *Pongamia glabra*, or *Galedupa arborea*, a honey brown and almost tasteless oil is procured, which is fluid at common temperatures, but gelatinises at 55 degrees. Other sources of oil are the *Celastrus paniculatus*, *Balanites Egyptiaca* and the saul tree (*Shorea Robusta*).

Cinnamon suet is extracted by boiling the fruit of the cinnamon. An oily fluid floats on the surface, which on cooling subsides to the bottom of the vessel, and hardens into a substance like mutton suet. The Singhalese make a kind of candles with it, and use it for culinary purposes. It emits a very pleasant aroma while burning. According to the analysis of Dr. Christison, it contains eight per cent. of a fluid not unlike olive oil; the remainder is a waxy principle.

Croton oil is obtained by expression from the seeds or nuts of *Croton Tiglium*, tree, 15 to 20 feet in height, belonging to the same order as the castor oil plant, producing whitish green flowers, and seeds resembling a tick in appearance, whence its generic name. It is a native of the East Indies. 160 parts of seeds afford about 64 of kernel. 50 quarters of croton nuts for expressing oil were imported into Liverpool from the Cape Verd Islands, in 1849.

The *Croton Tiglium* grows plentifully in Ceylon, and the oil, if properly expressed, might be made an article of trade. The best mode of preparing it is by grinding the seeds, placing the powder in bags, and pressing between plates of iron; allow the oil to stand for fifteen days, then filter. The residue of the expression is triturated with twice its weight of alcohol, and heated on the sand-bath from 120 to 140 degs. Fahrenheit, and the mixture, pressed again. In this step the utmost caution is necessary in avoiding the acrid fumes. One seer of seed furnishes by this process rather more than eleven fluid ounces of oil, six by the first step, and five by alcohol. The oil acts as an irritant purgative in the dose of one drop. In large doses it is a dangerous poison. When applied externally it produces pustules. In 1845, eight cases of croton oil and six cases of the seed were exported from Ceylon. Other species of Croton as *C. Pavana*, a native of Ava and the north-eastern parts of Bengal, and *C. Roxburghii* yield a purgative oil. The bark of *C. Eleuteria C. Cascarilla*, and other species is aromatic, and acts as a tonic and stimulant. It forms the cascarilla bark of commerce already spoken of. When bruised, it gives out a musky odour and is often used in pastilles. The oil obtained from the seeds of *Jatropha curcas*, a native of South America and Asia, is purgative and emetic, and analagous in its properties to croton oil. It is said to be a valuable external application in itch. In India it is used for lamps. *Oil of Ben*, known as Sohunjuna in Bengal, and Moringa in Malabar is obtained from the seed or nuts of the horse-radish tree, the *Moringa pterygosperma*, Burmann; the *Hyperanthera Moringa*, of Linnæus. This clear limpid oil having no perceptible smell, is much esteemed by watch-makers and perfumers; it is expensive and not often to be procured pure, consequently the oil would be a very profitable export. It grows rapidly and luxuriantly every where in Jamaica, particularly on the north side of the island—as well as in Trinidad and other quarters of the West. It is easily propagated either by cuttings from the tree (the branches) or by seeds, and bears the second year. The produce of each tree may be estimated at from one to two gallons. From the flowers a very pleasant perfume might be easily distilled. The following is the account of Dr. Hamilton. "It is a small tree, of about twenty feet in height, of most rapid growth, coming into flower within a few months after it has been sown, continuing to produce seeds and blossoms afterwards throughout the year. The tree is now naturalised in the West Indies. The timber is said to dye a fine blue, and the gum, which exudes from wounds in the bark, bears a strong resemblance to that obtained from the *Astragalus tragacantha*, for which it might, no doubt, be substituted. The numerous racemes of white blossoms with which the tree is constantly loaded, are succeeded by long triangular pods, somewhat torulose at the ends, and about two feet in length, when arrived at the full growth. These pods, while yet young and tender, are not unfrequently cooked and served up at the planter's tables like asparagus, for which they are not a bad substitute. The pods, when full grown contain about fifteen seeds; each considerably larger than a pea, with a membraneous covering expanding into three wings, whence the specific name of *pterygosperma*. On removing the winged envelope the seeds appear somewhat like pith balls; but upon dividing them with the nail, they are found to abound in a clear, colorless, tasteless, scentless oil, of which the proportion is so large that it may be expressed from good fresh seed by the simple pressure of the nail. Geoffry informs us, that he obtained 30½ ounces of oil from eight pounds of the decorticated seeds

being at the rate of very nearly 24 lbs. of oil from 100 lbs. of seed. Notwithstanding the great value of its oil, and the facility with which it can be obtained in the West Indies, the moringa has been hitherto valued there merely as an ornamental shrub, and cultivated for the sake of its young pods or the horseradish of its roots, as luxuries for the table. The oil is peculiarly valuable for the formation of ointments, from its capability of being kept for almost any length of time without entering into combination with oxygen. This property, together with the total absence of color, smell, and taste, peculiarly adapts it to the purposes of the perfumer, who is able to make it the medium for arresting the flight of those highly volatile particles of essential oil, which constitute the aroma of many of the most odoriferous flowers, and cannot be obtained by any other means, in a concentrated and permanent form. To effect this, the petals of the flowers, whose odor it is desired to obtain, are thinly spread over flakes of cotton wool saturated with this oil, and the whole enclosed in air-tight tin cases, where they are suffered to remain till they begin to wither, when they are replaced by fresh ones, and the process thus continued till the oil has absorbed as much as was desired of the aroma; it is then separated from the wool by pressure, and preserved under the name of *essence*, in well stopped bottles. By digesting the oil thus impregnated in alcohol, which does not take up the fixed oil, a solution of the aroma is effected in the spirit, and many odoriferous tinctures or waters, as they are somewhat inaccurately termed, prepared. By this process most delicious perfumes might be obtained from the flowers of the *Acacia tortuosa*, *Pancratium caribeum*, *Plumeria alba*, *Plumeria rubra*, and innumerable other flowers of the most exquisite fragrance, which abound within the tropics, blooming unregarded, and wasting their odours on the barren air." Three varieties of til are extensively cultivated throughout India, for the sake of the fine oil expressed from their seeds, the white seeded variety, the parti-colored, and the black. It is from the latter that the sesamum or gingelly oil of Commerce is obtained Sesamum seed contains about 45 per cent. of oil. Good samples of the oil were shown at the Great Exhibition from Vizianagram, Ganjam, Hydrabad, Tanjore, the district of Moorshedabad, and Gwalior. The gingelly seed is stated to be worth about £4 per ton in the North Circars. An oil resembling that of sesamum is obtained from the seed of *Guizotea oleifera* or *Abyssinica*, a plant introduced from Abyssinia, and common in Bengal. The ram til, or valisaloo seeds, yield about 44 per cent of oil. The oil is generally used for burning, and is worth locally about 10d. per gallon. BLACK TIL (*Verbesena sativa*) is known as kutsela or kala til, in the Deccan. It is chiefly cultivated in Mysore and the western districts of Peninsular India, as well as in the Bombay presidency. About Seringapatam, as soon as the millet crop has been reaped the field is ploughed four times, and the seed sown, a gallon per acre, during the month of July or August, after the first heavy rain. No manure or weeding is required, for the crop will grow on the worst soils. It is reaped in three months, being cut close to the ground, and stacked for a week. After exposure to the sun for two or three days, the seed is beaten out with a stick. The crop in Mysore rarely yields two bushels per acre, but about Poonah the produce is much larger. The seed is sometimes parched and made into sweetmeats, but is usually grown for its oil. This is used in cooking, but it is not so abundant in the seed, nor so good as that of the sesame. Bullocks will not eat the stems unless pressed by hunger. About 5,000 maunds are exported annually from Calcutta. 3,730 bags were imported into Liverpool in 1851. The price per quarter of eight bushels, in January, 1853, was from 30s. to £2; of teel oil, in tins, weighing 60 to 100 pounds, £2 to £2 4s. Bombay linseed was worth £2 11s. to £2 12s. the quarter of eight bushels, in January, 1853. Bengal ditto 2s. less. The imports into Liverpool were 68,468 bags and 54,834 packets in 1851, and 14,490 bags and 33,700 packets in 1853. About 9,000 bags of mustard seed and from 18,000 to 20,000 bags of rape seed are also imported thence. The price of the latter is about £2 the quarter.

Coco-nut oil.—The chief oil made on the sea board of India, is that yielded by the coco-nut palm. The nut having been stripped of the husk or coir, the shell is broken, and the fatty lining enclosing the milk is taken out. This is called cobri, copra, or copperah in different localities. Three maunds, or ninety pounds of copperah, are thrown into the mill with about three gallons of water and from this is produced three maunds, or seven and three-quarter gallons of oil. The copperah in its unprepared state is sold, slightly dried in the market. It is burned in iron cribs or grates, on the top of poles as torches, in processions, and as means of illumination for work performed in the open air at night. No press or other contrivance is made use of by the natives in India for squeezing out or expressing the oil from the cake, and a large amount of waste, in consequence of this necessarily ensues. *Bombay Times, June* 5, 1850. See COCOS.

Apricot oil.— Oil of the finest kind, is made in India by expression from the kernels of the apricot. It is clear, of a pale yellow color, and smells strongly of hydrocyanic acid, of which it contains, usually, about 4 per cent.

Sun flower oil.—"On inquiring into the use

made of the sunflower, we were given to understand that it is raised in Tartary chiefly for the oil expressed from it. But it is also of use for many other purposes. In the market places of the larger towns we often found the people eating the seeds, which, when boiled in water, taste not unlike the boiled Indian corn eaten by the Turks. In some districts of Russia the seeds are employed with great success in fattening poultry; they are also said to increase the number of eggs more than any other kind of grain. Pheasants and partridges eat them with great avidity, and they cause the same effects on them as other birds. The dried leaves are given to cattle in place of straw; and the withered stalks are said to produce a considerable quantity of alkali."—*Bremner's Interior of Russia.* 658 barrels linseed oil were brought down to New Orleans from the interior in 1849, and 1009 in 1848.

Linseed oil.—During the period of the Great Exhibition special enquiry was made by many manufacturers as to the different oils of Southern India, suitable for supplying the place of animal fat in the manufacture of candles, and generally adapted for various other purposes. Enquiries should be directed to the specific gravity, the boiling point, the per centage of pure oil in the seeds, and the means of obtaining a regular supply. The demand for vegetable oil in European commerce has been steadily on the increase for several years past, and the quantities consumed, are now so large that the oleaginous products of India and the colonies must sooner or later have a considerable commercial importance, from the value which they are likely to acquire.

Margosa, or Neem Oil.—From the pericarp or fleshy part of the fruit of the *Melia azaderachta*, and of the Azaderachta indica the well known Margosa oil is prepared; which is cheap and easily procurable. Dr. Maxwell, when garrison surgeon of Trichinopoly, stated that he has found this oil equally efficacious to cod-liver oil in cases of consumption and scrofula. He began with half-ounce doses, morning and evening, which were gradually reduced.

Bassia oils.—The seeds of three species of Bassia, indigenous to India, yield solid oils, and are remarkable for the fact, that they supply at the same time saccharine matter, spirit, and oil, fit for both food and burning in lamps.

a. The *Illepe* (*B. longifolia*) is a tree abundant in the Madras Presidency, the southern parts of Hindostan generally, and the northern province of Ceylon. In Ceylon the inhabitants use the oil in cooking and for lamps. The oil cake is rubbed on the body as soap, and seems admirably adapted for removing the unctuosity of the skin caused by excessive perspiration, and for rendering it soft pliable, and glossy, which is so conducive to health in a tropical climate. The oil is white and solid at common temperatures, fusing at from 70 to 80 degrees. It may be advantageously employed in the manufacture of both candles and soap; in Ceylon and some parts of India this oil forms the chief ingredient in the manufacture of soap.

b. Mahwa (*B. latifolia*) is common in most parts of the Bengal Presidency. The oil a good deal resembles that last described, obtained from the Illepe seeds; and may be used for similar purposes. It is solid at common temperatures, and begins to melt at about 70 degrees.

c. Vegetable butter is obtained from the Choorie (*B. butyracea*). This Bassia though far less generally abundant than the other two species, is common in certain of the hilly districts, especially in the eastern parts of Kumaon; in the province of Dotee it is so abundant that the oil is cheaper than ghee, or fluid butter, and is used to adulterate. It is likewise commonly burnt in lamps, for which purpose it is preferred to coco-nut oil. It is a white solid fat, fusible at about 120 degrees, and exhibits very little tendency to become rancid when kept.

d. Shea, or galam butter, is obtained in Western Africa from the *Bassia Parkii* or *Pentadisma butyracea*, a tree closely resembling the *B. latifolia* and other species indigenous to Hindostan. According to Park, the tree is abundant in Bambara, the oil is solid, of a greyish white colour, and fuses at 67 degrees. Its product is used for a variety of purposes—for cooking, burning in lamps, &c. This tree has much of the character of the laurel, but grows to the height of eighteen or twenty feet. Its leaf is somewhat longer than the laurel, and is a little broader at the point; the edges of the leaf are gently curved, and are of a dark sap green color. The nut is of the form and size of a pigeon's egg, and the kernel completely fills the shell. When fresh it is of a white drab color, but, if long kept, becomes the color of chocolate. The kernel, when new, is nearly all butter, which is extracted in the following manner:—The shell is removed from the kernel, which is also crushed, and then a quantity is put into an earthen pot or pan, placed over the fire with a portion of water and the nut kernels. After boiling slowly about half an hour the whole is strained through a grass mat into a clean vessel, when it is allowed to cool. Then after removing the fibrous part from it, it is put into a grass bag and pressed so as to obtain all the oil. This is poured into the vessel along with the first-mentioned portion, and when cold is about the consistence of butter. The nuts hang in bunches from the different boughs, but each nut has its own fibre, about seven or eight inches long, and about the

thickness and color of whip-cord. The nut is attached to the fibre in a very singular manner. The end of the fibre is concealed by a thin membrane, about half an inch wide and three-quarters of an inch long. This membrane is attached to the side of the nut, and, when ripe, relinquishes its hold, and the nut falls to the ground, when it is gathered for use. A good-sized healthy tree yields about a bushel of nuts, but the greater number are not so prolific. The trees close to the stream present a more healthy appearance, probably on account of being better watered, and the fire being less powerful close to the stream.—*Simmonds.* The collection of oils exhibited at the Madras Exhibition of 1855, by Lieut. Hawkes, was very extensive, and contained a very large number of highly interesting specimens. The series exhibited the oleaginous products in a state of great purity, accompained by the oil seeds yielding them. No consideration of cost or trouble had been allowed to interfere with providing all that was necessary to render the collection a complete illustration of the oils of Southern India. The value of the collection was greatly enhanced by the care which had been bestowed in the preparation, and the exclusion of all impurities in the process of extraction.—*M. E. R. J.* This officer, as Reporter to the Jury, on the Sub Class "*oils,*" published in the Reports of the Juries of the Exhibition, furnished observations on the extensive collection of oils, himself and others exposed. For the opportunity of having this done however, Southern India is indebted to Lord Harris, to whom this part of the Empire owes more for the practical development of its productive resources, than to any one since the days of James Anderson, Buchanan Hamilton, Heyne, Roxburgh and Ainslie by whom their existence was first made known. From the General and Local Exhibitions which as Governor of Madras he caused to be held in 1855-56 and 1857, the Commercial world and men of Science have been indebted for the learned essays, in the Juries Reports which emanated from Dr. H. F. C. Cleghorn, M. D. Dr. A. Hunter, M. D. Lt. H. P. Hawkes, Dr. A. J. Scott, M.D. Lieutenant Colonel Balfour, C.B. and Colonel G. P. Cameron, C.B.K.T. and K.C.

The *Adul oil* of Travancore was forwarded to the Great Exhibition of 1851, but merits further attention It seems to be medicinal, but the Botanical name of the plant producing it is not given.

(5741) *Aleurites Triloba.* Belgaum Walnut oil.

Hidjlee Badam Ka tael, HIND.

The Molucca tree which produces the "Lumbang nut" grows plentifully near Hydrabad. The nuts yield a very large per centage of Oil, and the tree is found to be very prolific. The nuts are said to be strung upon a thin strip of bamboo, and when lighted will burn like a candle; a notice of this interesting substance may be found in the Transactions of the Agri-Horticultural Society of India. (Vol. 8. p. 220.)—*M. E. J. R.*

(5742) *Allium sativum.* Garlic Oil.

Vellay-Poondoo yennai, TAM.

Good specimens of this medicinal oil were exhibited by Major Miller, the Madras Tariff and Lieut. Hawkes.—*M. E. J. R.*

(5743) *Anacardium occidentale.* Cashew nut oil.

Moondree cottay yennai, TAM. | Kajoo ka tael, HIND

The light yellow, sweet tasted and edible oil obtained from the *nut* of this tree, is in every respect equal, if not indeed superior, to either Olive or Almond oil. It is very seldom prepared, the nuts being used as a table fruit.—*M. E. J. R.*

(5744) *Anacardium occidentale. Cashew Apple Oil.* This powerfully vesicating oil obtained from the pericarp of the Cashew Apple has been long known to the Native Physicians, and much resembles in its properties the acrid oil obtained from the marking nut (Semecarpus Anacardium). —*M. E. J. R.*

(5745) *Andropogon Calamus Aromaticus.*—Roosa Grass Oil. This Oil differs but little either in appearance or quality from the Lemon Grass Oil. It is used for the same purposes.

(5746) *Andropogon Schœnanthus.*—Lemon Grass Oil.

Camachie Pilloo Tylum, TAM.

This well known Oil is obtained by distillation from a grass, which grows plentifully in many parts of the country. It is much used as a rubefacient for Rheumatic affections, as well as in Perfumery, for which purposes it is said to be largely exported from Travancore. When newly made, this Oil is of a light straw color, but age changes it to a deep red. Excellent specimens are exhibited by the Travancore and Tanjore Local Committees and by Lieut. Hawkes. Mrs. Goodsir forwarded an excellent sample obtained from Ceylon.

(5747) *Anethum Sowa.*—Bishops Weed Oil. These well known carminative seeds yield by distillation a very useful Oil which is given medicinally, as a stomachic. Good specimens were shown by Mr. Gay, the Tanjore Local Committee and Lieut. Hawkes.

ANIMAL OILS.

(5748) *Fish Oil.*—The preparation of fish oil is chiefly confined to Malabar and the Western Coast whence it is exported to England in large quantities, the demand is also yearly increasing.

(5749) *Fish Liver Oil.*—Is also prepared chiefly on the Western Coast although some is now made at Madras. The liver of the white shark is that generally used. The mode of pre-

paring the best Cod liver oil which is equally applicable to "Fish liver" is thus described.

"*Cod Liver Oil.*"—The proper season for preparing this oil is early in January when the livers are plump, firm, large, white, and full of oil—the livers are sometimes found diseased, and are specifically lighter than water, these should be rejected. Good livers should cut smooth, and not tear, when cut none of the substance should flow out in a half liquid state. The quantity of oil produced by livers depends much upon the time of the year. In the beginning of January 1000 livers were found by experiment to yield 37 Imperial gallons, and at the end of February an equal number only gave 23 gallons of oil. In the beginning of January 1000 livers of average size weighed 900 lbs. whilst in the last day of March the same number weighed only 575 lbs. The oil at these different seasons was equally pale, and the livers equally white, although much smaller and more flabby in the latter season. To prepare the oil—Wash the liver very carefully, first removing the gall bladders which adhere to them, and infuse them in rain or other water free from salt. Place them over the fire and never allow the heat to exceed 120 or 130°. On this head especial care must be taken, a higher degree of heat although yielding a larger product, communicates a rank fleshy taste and smell and heightens the color of the oil, thereby rendering it disgusting to the patient.

(5750) *Neats foot Oil.*—Its uses as a softener of leather, &c &c. are well known.

(5751) *Oleum Ceræ Oil of Wax.*—Bees wax submitted to destructive distillation with the addition of a little salt yields an empyreumatic oil which is much used in medicine by Native Doctors.

Guana Oil.—A specimen of this oil is exhibited by J. Rohde, Esq. of Guntoor.

(5752) *Arachis hypogea. Ground nut Oil.*

Vayr-cuddala-yenai, TAM.	Willayettie-moong kie-
Manilla noona, TEL.	phullie-ka tel, HIND.

This valuable oil, which of late years has been exported from Madras to a large amount, is obtained by expression from the seeds of the Ground or Manilla nut, which is now cultivated to a considerable extent in most parts of the Peninsula. In the year 1848-49—37,000 gallons were shipped, but in the two following years the Exports exceeded 1,00,000 gallons. It has however fallen to 57,207 gallons in 1852-53. It does not seem to be consumed to any large extent in this country, although the nut itself is much eaten by the poorer classes. It is said to be used for adulterating gingely oil in North Arcot, where it costs from Rs. 1-8-0, to 2-12-0 per maund. In the Nellore District, the seeds are procurable at Rs. 1-8-0 per maund and in Tanjore about 200 acres are cultivated, producing annually 75 candies of oil at Rs. 2-6-9 per maund. The seeds yield about 43 per cent. of a clear straw coloured edible oil, which is an excellent substitute for olive oil, and makes a good soap. Its value in London in January 1855 was £47-10 per ton. Perfect decolorization, far from depreciating, considerably enhances the value of this oil.—*M. E. J. R.* See GROUND NUT.

(5753) *Argemone mexicana.* Brumadundoo or Coorookoo oil. Prickly Poppy; Jamaica yellow thistle.

Brumadundoo yennai, TAM.	Fariugie datura ka tael.
Brumadundie Noona, TEL.	HIND.

This pale yellow limpid oil may be obtained in large quantities from the round corrugated seeds of the prickly poppy, which was originally introduced from Mexico in ballast, but now flourishes luxuriantly in all parts of India It is sometimes expressed by the natives and used in lamps, but is doubtless adapted to other and more important uses. In North Arcot it costs from Rs. 1-14-0 to Rs. 2-1-0 per maund.—*M. E. J. R.*

(5754) *Bassia Longifolia.* Illoopoo Oil.

Illepie Yennai, TAM.	Mohay ka tel, HIND.

This semi-solid oil is expressed from the seeds of a tree which is everywhere common in Southern India. It is seldom sold in the bazar, but the seeds are collected, and the oil manufactured by the Natives for private consumption. The seeds contain about 30 per cent of oil of a bright yellow colour. It is procurable in South Arcot at Rs. 25 per candy, or Rs. 1 4 0 per maund—in Bellary at 3 8 0, in Bhopaul at Rs. 3 12 0. In Tanjore, it may be had to the extent of 2,702 candies at the rate of 2 8 8 per maund.

Uses.—This oil makes excellent candles and soap. Of the latter, several specimens were contributed (Cl. xxix) from Tanjore, Madras, &c. Its chief use is, however, for burning in lamps, and as a substitute for butter in Native cookery. The very great difference in colour, consistence and flavour, which is observable in the many specimens of this oil entirely attributable to the mode of preparation, and to the presence in some cases of a very large proportion of mucilage and other extraneous matter. A bright colored specimen from Tanjore, on being treated with dilute sulphuric acid, proved remarkably pure, samples of the same oil, from Rajhamundry and Tinnevelly and from Lieut. Hawkes were equally good, but those from Nellore and Mysore deposited a large amount of mucilage.—*M. E. J. R.*

(5755) *Bassia Latifolia.* Mahwa Oil. Several specimens of oil under this name were exhibited, at the Madras Exbutition of 1855 but doubt existed as to their being really the produce of the B. latifolia, which has always been described as a solid oil or butter, whereas tho se now shown are quite liquid at ordinary temperature.

The B. latifolia is produced plentifully in Bengal, but it is not yet ascertained that it grows in the Madras Presidency.—*M. E. J. R.*

(5756) *Bombax pentandrum.* Silk Cotton seed Oil. A dark brown though clear oil is obtained by expression from the seed of the silk cotton tree, the fibre of which is largely used as a stuffing for pillows, mattresses, &c. &c.

(5757) *Bryonia Oil.*

Toomuttikai yennai, Tam. | Boddama kaia noona, Tel.

This oil is used for burning in Lamps in some parts of the country, where the fruit abounds. It is extracted by boiling in water, and is procurable only in very small quantities.—*M. E. J. R.*

The *Broonga Malagum Ointment* and the *Vishnamoosty or snake tree ointment* of Masulipatam appear to be new products, but being unaccompanied with any information as to source from which they are derived, this cannot be accurately determined.

(5758) *Butea Frondosa.* Moodooga Oil. The seeds of this tree yield a small quantity of a bright clear oil which is sometimes used medicinally.—*M. E. J. R.*

(5759) *Cabbage seed Oil.* Exhibited in the Madras tariff.—*M. E. J. R.*

(5760) *Calophyllum calaba?* A new oil under the name of *Cherroo Pinnacottay* is sent from Cochin.

Major Miller, Assistant Commissary General, Bangalore, forwards a new oil under the name of "Pootronjie." The same oil was also shown by Mr. Rose of Madras and Lieut. Hawkes.

(5761) *Calophyllum inophyllum.* Pinnacotay or Poon-seed oil.

Pinnay yennai, Tam. | Surpunka tael, Hind.
Pinnay noona, Tel.,

The fresh seeds of the "Alexandrian laurel" when shelled, and subjected to pressure yield a dark green oil of a peculiar odour. Old seeds yield a higher colored and thicker product. In the year 1847-48, Galls 3,871 of the oil, and cwt. 508 of the seeds, were shipped from Madras chiefly to Ceylon and the Straits, it has now ceased to be an article of Export. In Tanjore, 437 acres producing on an average 24⅝ cullums per acre of seed are covered with this tree: this yields 2671¼ maunds of oil at Rs. 20-4 per maund. In Tinnevelly, it costs As. 4-8 and Trichinopoly As. 4 per seer. In Tanjore, it is used for Lamps, and for caulking vessels, but it appears to be chiefly valuable as a medicine. It is seldom procurable in the bazar, but is expressed when required. Samples from Canara, under the name of "Honay," from Goa by the name of "Oleum unda," from Cochin called "Perun Poonaka," and from Masulipatam.—*M. E. J. R.*

(5762) *Cannabis sativa.* Hemp seed oil.

Ganja yenna, Tam.

This oil is obtained by expression from the seeds of the common hemp, which is cultivated in many parts of the country. In Russia, the oil is much used for burning in Lamps, but it is unknown to the natives of India. Three specimens are exhibited, one of a deep green colour from Tanjore, another of an olive green sent by Lieut. Hawkes and the third in the Madras Tariff.—*M. E. J. R.*

(5763) *Cardamom seed Oil.* (Fixed.) This is sent as a "new oil" by Mr. Rose, but is already well known.

(5764) *Carthamus tinctorius.* Safflower oil.

Chendoorookoo yennai, Tam. | Kurrur or Coosum ka tael, Hind.
Koosumba noonay, Tel.

A light yellow clear oil obtained from the seeds of the plant, yielding the well known dye. It grows plentifully in Mysore and Tinnevelly. In Mysore and Bellary, it costs about Rs. 2-8-0 per maund, and is used for lamps, culinary and other purposes.—*M. E. J. R.*

(5765) *Celastrus paniculata.* Malkungunee or staff tree oil.

Valuluvy yennai, Tam. | Malkungunee ka tael,
Bavungie noona, Tel. | Hind.

The deep scarlet colored oil obtained by expression from the seeds of this shrub is used in medicine, the seeds submitted to destructive distillation yield the oleum nigrum.—*M. E. J. R.*

(5766) *Celastrus Paniculata.* Oleum Nigrum.

Vaylarie tylum, Tam.

An empyreumatic oil obtained by the destructive distillation of the seeds of this Celastrus, either alone or in combination with other ingredients. It is much used in the treatment of Beri-beri, Malcolmson's Essay, p. 312.

(5767) *Cheerongie Oil Chirongia sapida or Buchanania Latifolia.*

Saraypuppoo noonay, Tel. | Cheeronjie or Charoolie ka tael, Hind.

The kernels of this tree are eaten by the natives to promote fatness, they abound in a straw colored, sweet tasted and limpid oil which is seldom extracted. The tree grows plentifully in Mysore and Cuddapah.—*M. E. J. R.*

(5768) *Cocos nucifera.* Cocoanut oil.

Taynga yennai, Tam, | Narel-ka-Tel, Hind.
Tencaya Noona, Tel.

The average annual quantity of this oil exported from Madras, from 1847-48 to 1852-53 is about Galls 9,00,000 per annum. Of this by far the largest portion is sent to the United Kingdom and France, the remainder finds its way to Arabia, Mauritius, Bombay and the (Indian) French Ports.

Price.—The prices of this oil vary considerably in different parts of the country. For the quarter ending 31st October 1854, the max: and the min: were Rs. 8-5-4 at Jubbulpore, and Rs. 1-12-9 at Mhow per maund. The average of twenty one large stations in the Madras Presidency giving Rs. 4-9-5 per maund, or about £41-2 per ton. The market-value of "Cochin oil" in London (January 1855) was £46. 10— the average being £46 to 48. The best oil is that exported from Cochin, and the neighbouring ports on the Malabar Coast. It usually fetches 20*s.* per ton more than the Ceylon or Coromandel coast article.

Uses. In Europe, for Candle and soap manufacture, for lubricating machinery, &c. &c. In India, for making soap, anointing the person, for cookery, lamps and in medicine.—*M. E. J. R.* See Cocos. W. E. Underwood, Esq., exhibits an empyreumatic oil and pyroligneous acid obtained by the destructive distillation of cocoanut shells. The latter substance has been used successfully in developing photagraphs by the collodion process. The oil or tar mixed with ordinary "japan varnish" is said to be used with advantage in the "backing up" of positive pictures.

(5769) *Croton tiglium.* Croton or Napaulah oil.

Neervalum yennai, Tam. | Jumal-gotay-ka tael, Hind.
Naypalum vittiloo, Tel. |

This is a well known medicinal oil, the use of which as a drastic purgative, seems to be decreasing.—*M. E. J. R.*

(5770) *Cucumis Colocynthis.* Colocynth seed Oil.

(5771) *Cucumis melo*, Melon seed Oil. Pitcha Pusjhum—Tharbooza, Khurbooza, Pumpkin seed Oil.

(5772) *Cucurbita pepo*, Cucumber seed Oil.

Valerikoi yennai, Tam. | Thosa noona, Tel.

A clear edible oil.—*M. E. J. R.*

(5773) *Garcinia pictoria*, Gamboge Butter. (Rox.)

Mukki-tylum, Tam. | Arasinagoorghy yennai, Can.

The solid butter contained in the seeds of the "Gamboge tree" a species closely allied to the G. purpurea which produces the "cocum butter" has attracted attention. The Gamboge tree grows abundantly in certain parts of the Mysore and Western coast jungles. The oil which is procurable in moderate quantities, is prepared by pounding the seed in a stone mortar and boiling the mass, until the butter, or oil rises to the surface. Two and a half measures of seed should yield one seer and a half of butter. In the Nuggur Division of Mysore, it is sold at the rate of As 1-4 per seer of 24 Rs. weight, or at £36-6 per ton, and is chiefly used as a lamp oil by the better classes of natives, and by the poor as a substitute for ghee. The butter thus prepared does not appear to possess any of the purgative qualities of the Gamboge resin, but is considered an antiscorbutic ingredient in food. The above interesting particulars have been furnished by H. R. Oswald, Esq. M. D. Nuggur Divison, Mysore Commission.—*M. E. J. R.*

(5774) *Ghirgilly Oil.* From Canara obtained from the pulp of the tree; considered an excellent remedy for Rheumatic pains.

(5775) *Guilandina Bonduc.* Bonduc nut Oil.

Calichikai yennai, Tam.

The oil of this common seed is mentioned by Ainslie, as being considered useful in convulsions and palsy. The seeds themselves are believed to possess tonic virtues. Used solely as a medicine.—*M. E. J. R.*

(5776) *Guizotia oleifera*, Ramtill oil—Vebesina sativa.

Valeesaloo Noonay, Tel. | Kala Till ka Tael, Hind.

This sweet tasted edible oil is plentiful in the Mysore, Vizagapatam and Ganjam Districts. It is used for nearly the same purposes as the sesamum. It is procurable in the Nuggur Division of Mysore at Rs. 3 8 0 per maund, but is considered inferior to gingely oil.—*M. E. J. R.*

(5777) *Hura Crepitans.* Sand Box tree oil, The seeds of this tree (which has been introduced from Jamaica) yield by expression an oil, as the whole tree abounds in poisonous matter, this oil probably partakes of its deleterious nature. The tree grows in the Madras Horticultural Gardens.

(5778) *Hydnocarpus inebrians.* Thortay Oil. From Canara a very valuable vegetable tallow, used for sores.

(5779) *Inga dulcis.* Coorookoopilly Oil. The seeds of this common hedge plant yield by expression a light coloured oil, about the consistence of castor oil. Its qualities and uses require to be ascertained.

(5780) *Iatropha (Curcas) Purgans.* Angular-leaved Physic-nut Oil.

Caat-amunak yennai, Tam. | Junglie erundie ka tel, Hind.
Adevee amedapoo noona, Tel. |

This oil, which has of late been imported into England, as a substitute for Linseed oil, is expressed from the fruit of a species of Iatropha, which abounds in all parts of the Madras Presidency. The colour is somewhat paler than the best linseed oil. It can be obtained in some parts of the country where it is plentiful, for little more than the cost of manufacture. It is now chiefly used in lamps. A light straw colored specimen was shown by Lieutenant Hawkes and several good but rather high colored samples from the

Tanjore and Travancore Local Committees and the Madras Tariff.—*M. E. J. R.*

(5781) *Jatropha glauca.* Glaucous leaved Physic nut Oil.

Addale or Authaulay yennai, TAM.

This oil which in appearance approaches castor seems to be but little known. It is fluid and light straw colored, and is procurable in South Arcot, where the plant grows on waste land. It is now chiefly used medicinally as a counter irritant, but if procurable in sufficient quantity seems likely to prove an useful oil. A high colored specimen was sent from Tinnevelly and one of a pale straw colour from Lieutenant Hawkes. —*M. E. J. R.*

(5782) *Lepidium sativum*—Country Cress Oil.

Alie-veric yennai, TAM.

This oil is extracted from the seeds of the "Chinese wall cress." Its qualities and uses have yet to be determined. It must not be confounded with "Linseed oil" the Tamil name of which is the same as that of the present article.

(5783) *Linum usitatissimum.* Linseed oil.

Alliverie yennai, TAM. | Ulsee ka tael, HIND.
Avecsee noona, TEL. |

The seed from which this oil is expressed, has long been cultivated to a limited extent in Nagpore, Bellary and other parts of the Madras Presidency. There is an impression that the oil obtained from the Indian plant is inferior to that imported from England, but it will be found on experiment, that this arises from the former having been imperfectly freed from mucilage, which prevents its drying. The seed is now an article of export from Madras to the amount (1852-53) of cwt. 1,106. In the year 1852-53, English Linseed oil to the amount of galls 4-552 and valued at Rs. 8.763 was imported into Madras, whilst at the same time cwt. 1,045 of the seed were exported from hence mostly to England: it appears that it can be made on the spot for much less than the average value of the English oil. This fact, it is hoped, needs only to be pointed out, to be taken advantage of. It would, however, be necessary to guard against the adulteration of this oil, with any of the other greasy oils which would of course infallibly destroy its drying properties. —*M. E. J. R.* See FLAX.

(5784) *Macassar Oil.* The qualities of this oil which is said to have been obtained from Macassar, the capital of the Celebes Island, require to be determined, it is used by the natives of Singapore as a hair oil.

(5785) *Manaloo Oil.* From Canara used for lamps.

(5786) *Azadirachta Indica; et Melia Azadirach.* Margosa or Neem oil

Vaypum yennai, TAM. | Neem ka Tael, HIND.
Vapa noona, TEL. |

This valuable and much used medicinal oil is obtained by either expression or boiling, from the seeds of the above mentioned trees, which are common throughout Southern Asia. It enters much into the practice of native Physicians, by whom it is administered internally as an anthelmintic, and externally as a liniment in Rheumatism, headache and as an application to ulcers. The oil is of a deep yellow colour, has a strong smell and an unpleasant bitter taste. In the year 1847-48 galls 1,587 were exported from Madras, and in the year 1851-52, galls 1,917, in 1852-53, galls 3,111. The chief market is Ceylon, but the demand is not constant.—*M. E. J. R.*

(5787) *Mesua Ferrea.* Naga-sumpunghee Oil. This valuable oil is procurable in Canara, at the rate of Rs. 4 and the seed at 1-8-0 per maund. It is used both as a lamp oil and as a healing application to sores.

(5788) *Mimusops elengi.* Mimusops Oil. A medicinal oil. Obtainable in tolerably large quantities in some parts of the Country. It is known in England.—*M. E. J. R.*

(5789) *Mooroogana tallow.* This valuable substance which even at high temperatures is perhaps the most solid oil with which we are yet acquainted, was forwarded from Canara by F. N. Maltby, Esq. If procurable in large quantities, and at a moderate cost, it promises to be a valued material for the manufacture of candles, &c. &c. It is used for medicinal purposes, &c. &c. and as a cure for cattle wounded by Tigers.

(5790) *Hyperanthera moringa*: *Moringa Pterygosperma.* Ben or Moringa oil.

Morunghy yennai, TAM. | Sahujna, HIND.
Morunga noona, TEL. |

Ben nut oil has long been considered valuable on account of the lengthened period, which it may be kept without contracting rancidity. The tree from which the "nuts" are obtained, is common in all parts of the country, the flowers, leaves and fruit are eaten by the natives, and the rasped root is used by Europeans as a substitute for horse-radish, to which circumstance it owes its common name of "horse-radish tree." The oil however is seldom made in India, nor does it now form an article of export.—*M. E. J. R.*

(5791) *Myristica Moschata*, Nutmeg butter.

Jadipootrie tylum, TAM. | Japhul ka tael, HIND.
Jajikarra noona, TEL. |

Is obtained by expression from the nutmeg, it has an aromatic smell from the volatile oil it contains.

(5792) *Neeradimootoo oil.* Neerada.

Mootoo yennai, TAM. | Junglie badam ka tael, HIND.

This valuable oil was sent to the Exhibition under the various names of Neeradee-moo-

too, jungle Almond, Maroty, Tamana, Maravettie, Neervettie and Soorty. It is said to be in great repute, as a medicine amongst native practitioners, and the kernel enters largely into their prescriptions. It might probably be found of use in the arts, it much resembles almond oil but is rather thicker. The seeds cost in Madras As. 2–6 per seer.—*M. E. J. R.*

(5793) *Nigella sativa.* Fennel Flower Oil.

Carun Seeragum, TAM. | Kulonjee and Siah Danah,
Nulla Gillikarra, TEL. | HIND.

The black aromatic seeds of the nigella sativa, yield by expression a dark colored fragrant oil. —*M. E. J. R.*

(5794) *Papaver somniferum.* Poppy Oil.

Cas casa yennai, TAM. | Khush-khush ka tael,
Casa-casa noona, TEL. | HIND.

The poppy is largely cultivated throughout Malwa and the Opium districts, where the drying oil obtained from the seed is more extensively used than any other, both in lamps and as food. At Bhopaul the oil is procurable at the rate of Rs. 4-8-0 per maund of 25lbs. or £10-6 per ton By simple exposure to the rays of the sun in shallow vessels, this oil is rendered perfectly colourless. It is much prized by European artists. —*M. E. J. R.*

(5795) *Olive,* Wild, or Pootroojie Oil. Obtained by expression from a handsome tree growing plentifully in Canara and Mysore.

(5796) *Polanisia Viscosa.* Viscid Cleome Oil.

Nahi-cadaghoo, TAM.

This warm and pungent little seed when subjected to very powerful pressure, yields a moderate per. centage of a light olive green colored limpid oil, which promises to be useful for purposes requiring a very liquid oil.

(5797) *Poonga or Kurunj Oil.* Dalbergia arborea or Pongamia Glabra.

Poonga yennai, TAM. | Kurunj ka tael, HIND.
Kanoogoo noona, TEL. |

This oil, which in some parts of the Country is used to a large extent in adulterating lamp oil, is expressed from the seeds of a tree, common in most parts of the Madras Presidency. In North Arcot, Bellary, and the Nuggur Division of Mysore, the oil is procurable at Rs. 2-8-0 per maund. It is chiefly used as a lamp oil by the poorer classes.—*M.E.J.R.*

(5798) *Sahcottay Oil.* From Canara, used for cutaneous diseases.

(5799) *Santalum album.* Sandal seed Oil.

Chundana pusjilum yennai, TAM.

The seeds of the sandal wood tree yield by expression a thick and viscid oil which is burnt by the poorer classes in lamps.

(5800) *Santalum album.* Sandalwood Oil.

Chundana yennai, TAM.

Specimens of this oil are exhibited by the Salem and Canara Local Committees, the Madras Tariff and Lieut. Hawkes. The exports amount annually to about 100 cwt.

(5801) *Raphanus sativus.* Radish seed Oil. Exhibited in the Madras Tariff.—*M.E.J.R.*

(5802) *Ricinus communis, Castor Oil.* Fructibus minoribus.

Sitt-amunakei yennai, TAM. | Bareek erundie ka tel, HIND.
Chitt-amindialoo noona, [TEL. |

Two varieties of the Ricinus communis, one bearing small and the other large seeds, are produced all over India. The small seeded variety yields the best product, and is employed in preparing the oil exported for medicinal purposes.

Mode of Preparation.—The fresh seeds after having been sifted and cleaned from dust, stones, and all extraneous matters, and slightly crushed between two rollers, freed by hand from huskr and coloured grains, are enclosed in clean gunny. They then receive a slight pressure in an oblong mould which gives a uniform shape and density to the packets of seed. The "Bricks" as they are technically called, are then placed alternately with plates of sheet iron in the ordinary screw or hydraulic press. The oil thus procured is received in clean tin pans, and water the proportion of a pint to a gallon of oil being added, the whole is boiled until the water has evaporated, the mucilage will be found to have subsided and encrusted the bottom of the pan, whilst the albumen solidified by the heat, forms a white layer between the oil and the water. Great care must be taken in removing the pan from the fire, the instant the whole of the water has evaporated, which may be known by the bubbles having ceased, for if allowed to remain longer, the oil which has hitherto been of the temperature of boiling water or 212°, *suddenly* rises to that of oil or nearly 600°, thereby heightening the color and communicating an empyreumatic taste and odour. The oil is then filtered through blanket, flannel, or American drill, and put into cans for exportation. It is usually of a light straw colour, sometimes approaching to a greenish tinge. The cleaned seeds yield from 47 to 50 per cent of oil worth in England from 4*d.* to 5*d.* per lb. The following is the result of experiments made at Madras and Calcutta to ascertain the per-centage of oil in the Castor seed (January 27th, 1853.)

Calcutta.—1400 lbs of seed yield kernels and raw oil as follows :—

	Kernels.	Oil.
1st Sort.....	632lbs.....	324lbs.
2nd Sort.....	184lbs.....	87½lbs.
3rd Sort.....	164lbs.....	76½lbs.

Making a total of 980lbs. of kernels and 488lbs. of raw oil from 1,400lbs. of seed.

Madras.—1400 lbs. of seed yield raw oil as follows:

1st Sort	318 lbs. of oil.
2nd Sort	88 lbs. do.
3rd Sort	74 lbs. do.

Making a total of 480 lbs. of oil from 1400 lbs. of seed.

The Cost of the Madras oil is as follows:

1400 lbs. of seed at Rs. 3 3 per bag of 164 lbs.	27	3	4
Husking and selecting kernels and cooly hire	3	11	9
Crushing, moulding, pressing and boiling	2	7	1
Filtering and sundries	2	8	0
Overseer's pay, Godown Rent, &c. &c.	1	6	2
300 empty Quart bottles, corks &c.	34	4	8
Cleaning and Packing charges	4	8	0
Rs.	76	1	0

Or an average of Annas $4\frac{17}{300}$ per quart of First, Second and Third sort oil =4d per. lb.

Uses.—This oil is chiefly used as a mild Purgative. Soap of good quality may be made of it, but the cost and disagreeable smell which it communicates, preclude its general use.

Exports.—Average for the last 4 years 1849-50 to 1852-53 11,325 galls. per annum.

At the Madras Exhibition of 1851, the samples of this oil exhibited by Mr. Gay, Madras, Mr. Kohlhoff, Tanjore, and Monsieur Godefroy of Pondicherry, were particularly fine Mr. Gay's specimen was the clearest, and most limpid, and devoid of any offensive smell. These qualities however do not arise from any superiority of the seed, or care in extraction, but from repeated decolorization with animal charcoal, which in the opinion of many eminent Medical men, considerably detracts from its strength and efficacy. Appavoo Pillay of Tinnevelly, the Nellore Local Committee, and Lieut Hawkes also exhibited excellent specimens. When manufactured in the ordinary Native mill, this oil is sometimes used by the richer classes in Lamps.

Castor oil (extracted hot.) This differs from the preceding only in the mode of preparation—The seeds are boiled for two hours in water, dried for three days in the sun, freed from the shells, pounded and then boiled in fresh water, until the whole of the oil has risen to the surface. Five seers of the seeds or $3\frac{1}{8}$lb. should by this process yield a quart of oil. This is the sort generally used in medicine by native practitioners, it is straw colored, and free from any unpleasant taste or smell.—*M.E.J.R.*

(5803) *Ricinus communis.* Castor or Lamp oil.; fructibus majoribus.

Vullak ennai, TAM.	Chirach-ka-tel, HIND.
Ped-amidum, TEL.	

This oil which is obtained from the large seeded variety of the "Ricinus communis" is sometimes drawn cold, and a straw-colored specimen scarcely distinguishable in quality from the oil of the small seeded variety was shown by Lieut. Hawkes. It is however more usually extracted by heat, and forms the common "Lamp oil" of the Bazar.

Mode of preparation—The seeds having been partially roasted over a charcoal fire, both to coagulate the albumen and to liquify the oil, are then pounded and boiled in water until the oil rises to the surface. The roasting process, however gives it a deeper red colour and an empyreumatic odour.

Price.—The price of this oil varies in different parts of the country from Rs. 1 10 0 to Rs. 3 13 6 per maund of 25lbs. The average of nineteen large stations, in all parts of the Madras Presidency for the Quarter ending 31st October 1854, was Rs. 2 8 6 per maund.

Uses.—Chiefly for lamps.

Exports.—Average of the last six years. Galls. 27,561 per annum.—*M. E. J. R.* See CASTOR OIL.

(5804) *Castor Oil.* Wild. (A new species) from Canara. Is burnt in lamps.

(5805) *Sapindus emarginatus.* Soapnut oil.

Poovandie cottay or Poongum-kai yennai, TAM.	Koocoodie noona, TEL.
	Reethay ka tael, HIND.

This semi-solid oil is used medicinally by the natives, and is extracted from the kernel of the Soap-nut. Its cost prevents its general use.—*M. E. J. R.*

(5806) *Sarcostigma Kleinii.* Poovana Oil. Was exhibited by the Tinnevelly and Travancore Local Committees, and by the Rev. E. Johnston, Cottayam, and is reported to be useful in Rheumatism.—*M. E. J. R.* The Revd. E. Jonstone of Cottayam forwarded a specimen of the oil of *Sarcostigma Kleinii.* This substance has been long known under the name of Poovana and Poovengah, but the exhibitor was the first to ascertain its correct Botanical name. This medicinal oil is used largely on the Western Coast, and seems especially to merit further investigation.—*M. E. J. R.*

(5807) *Semecarpus anacardium.* Marking nut Oil.

Shavng cotty yennai, TAM.	Bhillawan ka tael, HIND.
Nellajie noona, TEL.	

The acrid and vesicating oil which is found between the two laminæ of the pericarp of the marking nut is collected and used as a preventive against the attacks of white ants, and by native practitioners in rheumatic and leprous affections. By boiling the whole nut not divested of its pericarp, an oil is also obtained which acts as a blister. The preparation or collection either of the oil or acrid juice is liable to cause

much irritation and inflammation of the hands, face, &c, of those engaged in the work.—*M. E. J. R.*

(5808) *Sesamum Orientale.* Gingeley or Sesamum Oil (black seeded variety.)

Nool ennai, TAM.	Meetha Till ka tael,
Mundie noonay, TEL.	HIND.

This oil which is perhaps consumed to a greater extent than any other by the Natives of India, is, moreover, second only to cocoanut oil in its importance as an article of commerce. It is extensively cultivated throughout the whole of the Madras Presidency, and has been exported as follows.

Gingeley Seed.

Years 1847-48	Years 1848-49.
Qr. 17,518....Rs. 1,60,134	Qr. 8,594 ... Rs. 1,02,726
Years 1849-50.	Years 1850 51.
Cwt. 1,44,125 Rs. 299,412	Cwt. 2,27,779 Rs. 4,37,185
Years 1851-52.	Years 1852 53
Cwt. 1,09,414 Rs. 302,559	Cwt. 2,51,613 Rs. 5,31,664

Gingeley Oil.

Years 1847-48.	Years 1848 49.
Gl. 19 520.....Rs. 14,766	Gl. 14,686.....Rs. 11 535
Years 1849-50.	Years 1850-51.
Gl. 52,721.....Rs. 36,294	Gl 77,262..... Rs. 48,605
Years 1851-52.	Years 1852-53.
Gl. 46,196.....Rs. 26,722	Gl 72,607.....Rs. 43,608

Of the gingeley seed exported in 1852-53 the United Kingdom received cwt. 12-713—Ceylon, cwt. 590—France, cwt. 2,87,225—Pegue, cwt. 741—Bombay, cwt. 113—Malacca, cwt. 33 and Travancore, cwt. 148. Of the quantity of oil (72,607 gals.) exported in the same year—gals. 42,043 were shipped to the United Kingdom—gals. 2,968 to Ceylon—gals. 4,232 to Mauritius and Bourbon—gals. 19,698 to Pegue—gals. 46 to Bengal—gals. 27 to the French (Indian) ports, and gals. 3,593 to Malacca.

Mode of preparation.—The great disparity of color observed in the specimens of this oil is to be attributed to the mode of preparation. The method sometimes adopted is that of throwing the fresh seeds, without any cleansing process, into the common mill, and expressing in the usual way. The oil thus becomes mixed with a large portion of the coloring matter of the epidermis of the seed, and is neither so pleasant to the eye, nor so agreeable to the taste, as that obtained by first repeatedly washing the seeds in cold water, or by boiling them, for a short time, until the whole of the reddish brown coloring matter is removed, and the seeds have become perfectly white. They are then dried in the sun, and the oil expressed as usual. This process yields 40 to 44 per cent. of a very pale straw colored sweet smelling oil, an excellent substitute for olive oil.

Uses.—In India, it is chiefly used in cookery, in anointing the person, for making soap, and for burning in lamps. In England, it is chiefly used for the manufacture of soap, and for burning in Table-lamps, for which it is better suited than cocoanut oil, owing to the lower temperature at which the latter congeals.

Price.—Value in England (January 1855) £47.10 per ton. In different parts of the Madras Presidency the price of this oil varies from Rs. 1 5 0 to Rs. 6 0 0 per maund of 25lbs. In S. Arcot it is procurable at Rs. 27 12 5 per candy. The prices per maund of this oil, at the undermentioned stations, for the quarter ending 31st October 1854, were as follow.

	RS.	A.	P.		RS.	A.	P.
Arcot, ...	3	8	0	Madura,.....	5	8	3
Bangalore,..	3	7	3	Mangalore,...	4	1	8
Bellary,.....	3	2	0	Nagpore,.....	1	12	0
Berhampore,	2	8	0	Palamcotta,...	4	12	0
Cannanore,...	6	0	0	Paulghaut, ...	3	7	0
Cuddapah, ...	2	13	0	Samulcotta,..	2	10	8
Jaulnah,.....	2	6	0	Secunderabad	2	3	11
Jubbulpore,..	1	5	0	Trichinopoly,	4	1	8
Madras,.....	3	14	0	Vellore,.....	3	14	0
Masulipatam,	3	0	0	Vizagapatam,	3	2	0

Excellent specimens of this oil were exhibited by the Cochin, Tinnevelly, Rajahmundry, Tanjore, Nellore and Canara Local Committees, by Mr. Kohlhoff of Tanjore, and Lieut. Hawkes.—*M. E. J. R.*

Second sort Gingeley Oil, erroneously called "Rape," (Kharasanee yelloo), red seeded variety. This oil is expressed from a variety of sesamum and differs but little from the one abovementioned. In Tanjore, it is procurable at Rupees 3-0-0 per maund.

The following particulars concerning the two varieties of plant, yielding this important oil have been furnished by F. Copleston, Esq., Rajahmundry.

Two varieties of Sesamum are cultivated for the sake of the oil.

The gingeley seed par excellence is the produce of the plant, which is sown in the month of March, after the rice crop, and is irrigated twice, once at sowing, and once afterwards. The seed which is *black*, and is called 1st sort gingeley, from the fact of its yielding the largest per centage of oil, ripens in May, and sells at the rate of Rs. 60 per candy of 500 lbs. The oil obtained from both varieties, sells at the same price, viz. Rs. 2 14 6 to Rs. 3 per maund of 25 lbs. according to quality.

Second sort gingeley is sown in June, and produces a *red* seed. The plant although a little larger resembles in most respects the former, it has, however, a somewhat longer leaf, and the flower differs a shade or two in color. A candy of 500

lbs. of this seed sells at Rs. 57-8 0. The price of the oil is the same as that of gingeley. This seed has of late been exported to France, in consequence of which the present price is double what it was three years ago.—*M. E J. R.*

(5809) *Sinapis species.* Mustard Oil.

Kadaghoo yennai, TAM. | Avaloo and Sursava noona, TEL.
Raye ka tael, HIND. |

Five or six species of Sinapis are cultivated in all parts of India, for the sake of the valuable oil they yield, those most frequently seen are *S. glauca, toria*, and *racemosa*. The seeds of the "sinapis alba" yields by expression 36 per cent of a bright yellow, pleasant tasted, edible oil, having a strong smell, and slight taste of mustard. The seeds of "sinapis nigra," yield only 28 per cent of an oil in all respects similar to the above. The average price of mustard seed in eighteen large stations, in all parts of the Madras Presidency, for the Quarter ending 31st October 1854 was Rs. 1-2-8 per maund of 25 lbs., the maximum being Rs. 1-11-6 at Cannanore and the minimum As. 10-5 at Nagpore. In Vizagapatam it costs Rs. 2-8 per Sicca garee. The oil is not exported, but the seeds have been shipped as follows:

In the years	1847-48.....	Cwt.	5,828
,,	1848-49.....	,,	6,767
,,	1849-50.....	,,	9,435
,,	1850-51.....	,,	9,9[illegible]9
,,	1851-52.....	,,	3,636
,,	1852-53.....	,,	16,075

Uses.—This valuable oil, although seldom sold in the Market, being made when required, is used in most parts of India in cookery, and is considered superior to all other oils for anointing the body, which it is supposed to invigorate. In medicine, it is sometimes given internally, but is more frequently applied as a rubefacient. Lieut. Hawkes, exhibited a complete and interesting series of oils and oil cake (common mustard) obtained from four different sorts of sinapis.—*M. E. J. R.*

(5810) *Sterculia Fœtida.* Fetid Sterculia Oil.

Coodira pusjun-yennai, TAM.

This semi-solid oil obtained by expression from the seeds of a large Jungle tree, appears to contain a large per centage of Stearine, but it is doubtful if it can be obtained in large quantities, it was sent to the Great Exhibition of 1851 from Bombay.—*M. E. J. R.*

(5811) *Strychnos nux vomica.* Nux vomica Oil.

Moo yettie cottay yennai, TAM. | Carun jooty, CAN.

An empyreumatic oil prepared from the fresh nut, is used medicinally by Native Practitioners. It was exhibited by the Travancore Local Committee under the name of Carunjooty oil.—*M. E. J. R.*

(5812) *Terminalia Bellerica.* Belleric Myrobalan Oil.

Tanikai yennai, TAM.

A medicinal oil obtainable in small quantities from the kernel of the Belleric Myrobalan, the use of this drupe as a tanning material is well known.

(5813) *Terminalia Catappa.* Wild Almond Oil. A specimen of oil said to be obtained from the fruit of this tree was exhibited in the "Madras Tariff," and a sample labelled "Almond oil" from Tanjore was the product of this species of Terminalia.—*M. E. J. R.*

(5814) *Terminalia Chebula. Chebulic Myrabolan.* A medicinal oil is procurable in very small quantities from the kernel.

(5815) *Thespesia populnea.* Portia nut oil.

Poorasun yennai, TAM. | Paris pippul, HIND.

This deep red colored and somewhat thick oil is obtained from the seeds of the portia tree, which grows in great abundance in the vicinity of Madras, and other parts of the Presidency. It is extensively planted as an avenue tree, for which its quick-growth and the beauty of its flowers render it a favorite. The wood is capable of being worked when fresh cut and is used for boat building and cabinet work. The juice of the tree is used on the western coast, as a remedy for various cutaneous affections, and the oil which is yet unknown to the natives, might probably be of use in similar cases. Its expense precludes its use otherwise than medicinally.—*M. E. J. R.*

(5816) *Thevetia Neriifolia.* The "Exile" Oil. The kernels of the seeds of this common shrub yield by expression a large per centage of a clear bright yellow colored oil, the qualities of which have not as yet been determined.

(5817) *Thoronogullo Oil.* Pongamia glabra? from Canara used for cutaneous diseases. An empyreumatic medicinal substance called *Tuntapoo oil* (*cassia tora?*) is contributed by the Masulipatam Local Committee.

(5818) *Vateria Indica.* Piney Tallow or Doopada Oil.

Piney Yennai, TAM.

This most valuable tree, which, besides the product under consideration, yields a resin nearly equal to copal, and furnishes an excellent building wood, grows plentifully in the jungles of the Western Coast. The oil which is perfectly solid even in hot climates, is prepared by cleaning the seeds, then roasting and grinding them into a mass. To 5 seers of seed, add 12 seers of water, and boil until the oil rises to the surface. Remove the oil, stir the contents of the vessel, and allow it to stand until the following day, when more oil will be observed on the surface, which may be collected and the process repeated. The oil is principally used for lamps, but is very

suitable for soaps and candle making.—*M. E. J. R.*

(5819) *Wood Oils.* This class of oils is obtained for the most part from the Burmese coast and the Straits. They are usually procured by tapping certain trees of the order Dipterocarpeæ, and applying heat to the cavity. The oil which flows from the wound, is a mixture of a balsam and volatile oil, and when applied as a varnish to wood or other substance the oil evaporating deposits a hard and durable coat of resin. They are chiefly used as natural varnishes, either alone or in combination with colored pigments, also as a substitute for Tar in paying the seams of shipping, and for preserving timber from the attacks of white ants They are said also to be useful as an ingredient in Lithographic inks. Owing to the distance from which they are brought, and the imperfect knowledge we yet possess of the countries whence they are imported, the names of the trees from which these valuable substances are derived, are involved in some degree of obscurity. The oil, therefore generally receives the names of the localities from which they are imported. Some of them differ considerably in colour and consistence, but they all possess the same balsamic odour, and are derived from various trees of the noble family of Dipterocarpeæ. In this section were remarked three good samples of good oil from Canara. Also a very interesting series of ten oils from various parts of the Madras Presidency and Burmah. Lieut Evans 51st Regt. N. I., in addition to other contributions, exhibits a bottle of wood oil from Malacca in its natural state as procured from the tree. The mode of extraction is as follows. " About the end of the dry season, that is in March or April, several deep incisions are made with an axe into the heart of the wood, and a good sized piece scooped out ; into these holes fire is placed, and kept burning until the oil begins to run, when it is received into a bamboo, and allowed to run slowly drop by drop."

(5820) *Teak Wood Oil.* An opaque dull ash colored oil under this name, is procurable in most of the large bazars of India ; when allowed to rest for some time, it separates into two layers, or an uppor dark colored clear stratum and a lower and more solid deposit. Its chief use is for applying to wood work of all sorts, either alone as a natural varnish, or in combination with certain resins.

(5821) *Wood Oil from Pegu.* It is much to be regretted that the Botanical names of the trees, yielding this and the following wood oils cannot with any certainty be ascertained. The oil which is generally known by this name is a very clear and liquid substance forming a natural varnish when applied to wood or other substance.

(5822) *Deodar or Shemanatahu Oil.* Erythroxylon areolatum. An empyreumatic medicinal oil.

(5823) *Wood Oil from Chittagong.* This substance much resembles the " The Teak Wood oil" and the " Wood oil from Pegu," above mentioned. It is less liquid than the latter, but is used for the same purpose; procurable in all large bazars.

(5824) *Wood Oil from Moulmein.*

(5825) *Wood Oil from Rangoon.* This appears to differ very considerably from any other specimen of " wood oil" in the Exhibition, it is quite white and almost solid—but has the usual resinous shell of this class of oils.

(5826) *Wood Oil* from Singapore.

(5827) *Wood Oil* from China.—Although scarcely coming within the limits of this report, this valuable product merits notice as being one of the substances of which the well-known and much prized China lacquer is mode. It is used in Singapore for painting the beams and woodwork of Native houses, and may also be mixed with paint when not exposed to the sun.

(5828) *Sissoo-Wood Oil.*—Dalbergia sissoo. An empyreumatic medicinal product.

(5829) *Wood Oil* from Tinnevelly. An empyreumatic product similar to tar, chiefly used medicinally by Native Practitioners.

(5830) *Camphor Wood Oil. Dryobalanop Camphora.*—The last of this series belongs to the class of " Volatile oils," but may be here noticed. The specimen exhibited by Lieut. Hawkes was forwarded to him from Singapore through Lieut. Heath of the 38th Regiment N. I., and another excellent specimen which is exhibited by Second Dresser Pulneandy was brought by him from Labuan. It is used largely in Singapore as a substitute for turpentine, and sells at from 15 to 20 cent. a bottle. The Jury consider Lieut. Heath and 2d Dresser Pulneandy deserving of Honorable Mention.

(5831) *Wood Oil,* as obtained from the tree without any preparation. This very interesting specimen which was before mentioned as being contributed by Lieutenant E. J. M. Evans, 51st Regt. N. I., by whom it was obtained from Malacca, is obtained from a large tree of the Dipteraceous family which is very common in the dense jungles of the Malayan Peninsula, and grows to a great height. When not topped too soon, the base of the trunk is often of immense girth—the wood is reddish brown and has a smell not unlike that of English fir, the bark is smooth, the leaves alternate, pinnate and exstipulate, fruit a one seeded drupe, seed angular and anatropal. The oil when permitted to remain at rest divides itself into two layers, the upper consisting of a clear chesnut colored liquid balsam and the lower being in appearance like flakes of granulated sugar and consisting probably of the surplus resin deposited by the action of the atmosphere. The Jury considered the Exhibitor deserving of Honorable Mention.

(5832) *Mineral Oils.* Specimens of *Petroleum* are exhibited by the Madras Tariff and Lieut. Hawkes, the produce of our Burmese Possessions. Its uses are well known. The Wound tree oil, or *Gayapanoona* of Rajahmundry although locally known for sometime, is now prominently brought to notice.

(5833) *Wrightia Antidysenterica.* Rosebay Oil.

Vaipallay yennai, TAM.

A medicinal oil—little known. A thick, scarlet colored, medicinal oil partaking doubtless of the properties of the seed.—*M. E. J. R.*

(5834) OLAY.

Olay, TAM. | Puttay, HIND.
Tatakoo, TEL. |

Are the three vernacular names by which the people designate the leaves, when prepared for being written upon, of the Palmyra (Borassus *flabelliformis*), of the cocoanut tree, and those of the Taliput palm (corypha umbraculifera). The oldest Hindoo author who alludes to writing on the Olay is Panniny rishee, who lived above 4160 years ago, and resided at Arittuwarum, near the source of the Ganges. Pliny says expressly (lib: xiii. cap: 2) that the most ancient way of writing was upon the leaves of Palms, from which, it is believed that the leaf (*folium*) of a book came to be synonymous with that of a plant. They are written upon with the style, which is pointed with steel and its handle sometimes highly ornamented. During the operation of writing, the leaf is supported by the left hand, and the letters are cut or scratched upon its surface with the style, which is kept always in the same position and the leaf is moved to the left hand side by means of the thumb. To render the characters more legible, the engraved lines are occasionally filled by smearing the leaves with fresh cow-dung, which is tinged black by rubbing the lines over with cocoanut oil, or a mixture of oil and charcoal powder, and for the same object, in Ceylon, an oil, called Doomale is sometimes rubbed on the letters with a burned rag. All the sacred books of the Hindoos, Burmese, Cingalese &c. are still made of these olay, some of them being highly ornamented. All accounts in the revenue department, all grants of land, leases, and all the accounts in shops are still kept on these leaves, and they are likewise sent as letters. Books are never much beyond two feet in length and two inches in breadth, they are said to last from one to four or five hundred years.—*Seeman.*

(5835) OLDENLANDIA BIFLORA. Two FLOWERED INDIAN MADDER.

Purputee, Papra, HIND.

Appears in moist ground in the rainy season. —*Genl. Med. Top. p.* 180. *Oldenlandia biflora* is very common in Bengal, and called in Bengali *Khet-papura*; other species also occur and are called *Gunda badalee*, and *Poonkhu.*—*O'Shaughnessy, p.* 400.

(5836) OLDENLANDIA UMBELLATA. CHAY ROOT PLANT. Lin.

Emboorel also Ramiseram vayr, TAM.

A native of Java, Coromandel, and Mexico; root long and orange-coloured, employed in Coromandel to dye an excellent red on cotton cloth; considered by the native doctors to be expectorant.—*O'Shaughnessy, p.* 400. The small, white, numerous leaves of this low growing plant, are slightly bitter, and unpleasant to the taste; the Native Doctors consider them as expectorant and prescribe them, accordingly in complaints of the Chest. When dried and pounded, they are also mixed with flour, and made into cakes, which are eaten by such as suffer from consumptive or Asthmatic affections.—*Ains. Mat. Med. page* 79. See CHAY ROOT.

(5837) OLEA a genus of plants the type of the natural order Oleaceæ. It has a 4-cleft corolla a berry with two brittle 1-seeded cells one of them generally abortive. The leaves undivided. Flowers greenish clustered, axillary. Olea Europea has lanceolate quite entire 2-coloured leaves with axillary racemes. It grows wild in rocky places in Italy. It differs from most trees except the sweet Bay (Laurus nobilis) some species of Cornus, and a very few others in yielding a fixed oil from the pericarp; the seed being the source of fixed oil, in most plants. The oil which is expressed from the ripe fruit immediately after being collected is most esteemed, and called Virgin oil Oleum Provinciale. That which is most highly prized comes from Nice and Genoa. When the oil is extracted by a stronger pressure or by the aid of heat or after the olives having been collected into heaps have remained till a kind of fermentation has occurred, it is the common olive oil, the properties of which vary in proportion as the fermentation has been of long or short duration. An oil of still inferior quality is obtained, when the husk of the olive after the former treatment is boiled in water. This kind is employed solely for the preparation of soap. Virgin Oil is of a very pale-yellow or yellowish-green colour more limpid when pure than any other fixed oil, indorous, when fresh; but emitting a very peculiar odour when old, taste purely oily but by age becoming slightly rancid. Common olive oil is of a deep greenish or brownish yellow colour, and an odour and taste more or less subrancid. Its specific gravity is greater than the other. The unripe fruit of the olive is preserved in brine. and eaten frequently at desert. The olive flourishes only in warm and comparatively dry parts of the world, as the south of France and Spain, in Italy, Sicily, Syria, and the north of Africa. Humboldt has stated that "the olive flourishes

between 36° and 44° N. lat ; wherever the mean annual temperature is from 62. 6 to 50°, where the mean temperature of the coldest month is not below from 41° to 42°8, and that of the whole summer from 71-6° to 73°4." Great cold is injurious to it, as that of 1709 was to the olive trees of France ; and as M. Bove states that the olive thrives in Egypt, and Delta that it contributes to the riches of the Fayoum, which is nearly in the latitude of Cairo, it is evident that it is capable of bearing a greater degree of heat, as is probable indeed from its being a native of Asia, having been cultivated in early times in Syria and Palestine by the ancient Hebrews, and known to them by the name of Zait, and to the Arabs by that of Zaitoon. It is said to have been introduced by the Phocæans into Marseille.—*Eng. Cyc.* Dr. Wight gives Olea clavata, 736; glandulifera, 1238 ; linocieroides, 1241 ; *paniculata*, 735 ; polygama, 1239-42 ; robusta, 1242 ; Roxburghii, 735.

(5838) OLEA DIOICA, Oleaceæ.

Koly marum, Tam.

According to Roxburgh the timber of this tree is reckoned excellent and is put to many uses by the inhabitants of Silhet ; a specimen of the wood did not accompany the flowering one, so that he was unable to offer any opinion on it.—*Wight.*

(5839)OLEA FRAGRANS, or KWEI HWA, is largely cultivated *in* China, for scenting tea.—*William's Middle Kingdom, p.* 288. *Olea fragrans*, the Qui Wha of the Chinese is by them planted in different parts of their gardens.—*Fortune's Tea Districts, p.* 17. Along the banks of a ditch, through which the tide ebbs and flows, there is a row of the *olea fragrans* This is the famous kwei-wha of the Chinese, and one of their most favourite flowers. It forms a good-sized bush, about as large as a lilac, and flowers in the autumn. There are three or four varieties, the main difference between them consisting in the colour of their blossoms. Those kinds which produce brownish-yellow flowers are the finest and are most highly esteemed by the natives. The bushes are seen growing near all the villages in the north-eastern provinces of the empire, and are plentiful in gardens and nurseries. When they are in flower in the autumnal months, the air in their vicinity is literally loaded with the most delicious perfume. One tree is enough to scent a whole garden. The flowers of the kwei-wha are a source of great profit to the Chinese cottages, as well as to the nurserymen, who produce them in large quantities for the market. There is a great demand for them in all the large towns. Ladies are fond of wearing wreaths of them in their hair; they are also dried and placed in ornamental jars, in the same way as we do rose-leaves in Europe; and they are used largely for mixing with the finer kind of tea, in order to give it an agreeable perfume. The fragrant olive, moutan, sacred bamboo (*Nandina domestica.*)—*Fortunes' Tea Districts, p.* 79.

(5840) OLEA EUROPEA. Olive Oil. *The Olive-tree.* There are several varieties of this plant, two of which have been long distinguished —the wild and the cultivated. The former is an evergreen shrub or low tree, with spiny branches and round twigs ; the latter is a taller tree, without spines, and with four-angled twigs. The fruit is a drupe about the size and colour of a damson. Its fleshy pericarp yields by expression olive oil, of which the finest comes from Provence and Florence. Spanish or Castile soap is made by mixing olive oil and soda, while soft soap is made by mixing the oil with potash. The wild olive is indigenous to Syria, Greece, and Africa, on the lower slopes of Mount Atlas. The cultivated species grows spontaneously in Syria, and is easily reared in Spain, Italy and the South of France, various parts of Australia and the Ionian Islands. Wherever it has been tried on the sea-coasts of Australia, the success has been most complete. There are several fine trees near Adelaide, some of them fourteen feet high, bearing fruit in abundance. Unfortunately no one has attempted to cultivate the plant on a large scale, but in a few years Australia ought to supply herself with olive oil. The olive tree is also grown in Hong-Kong. There are five or six varieties of *O. Europæa*, or *sativa*, grown in the south of Europe, of which district they are for the most part natives. The entire exports of olive oil from the kingdom of Naples have been estimated at 36,333 tuns a year, which taken at its mean value when exported at £62 per tun, is equivalent to the annual sum of £2,252,646. There are one or two distinct species, natives of the East Indies and the Cape of Good Hope. This genus of plants, besides their valuable products of oil and fruit, are also much admired for the fragrance of their white flowers. There is a yellow-blossomed variety, native of China, *O. fragrans*, the Lanhoa or Kwei Hwa, of the Chinese, which is used to perfume their teas. Olive oil now forms an article of export from Chili, being grown in most parts of that republic, particularly in the vicinity of St. Jago, where trees of three feet in diameter, and of a proportionate height, are common. The olive was first carried from Andalusia to Peru in 1560, by Antonio de Ribera, of Lima. Frezier speaks of the olive being used for oil in Chili, a century and a half ago. The culture of the olive has been recommended for Florida and most of the Southern States of America. Formerly, on account of its slow growth, the olive was not considered very useful ; but some years since a new variety was introduced into France, and into some parts of Spain and Portugal, which yields an abundant crop of fruit the second year after planting. They are

small trees or rather shrubs, about four or five feet high. The fruit is larger than the common olive, is of a fine green color when ripe, and contains a great deal of oil. The advantages accruing from this new mode of cultivating the olive tree, are beyond all calculation. By the old method an olive tree does not attain its full growth, and consequently does not yield any considerable crop under thirty years; whereas the new system of cultivating dwarf trees, especially from cuttings, affords very abundant crops in two or three. An acre of land can easily grow 2,500 trees of the new variety, and the gathering of the fruit is easy, as it can be done by small children. At Beaufort, South Carolina, the olive is cultivated from plants which were obtained in the neighbourhood of Florence, Italy. A gentleman in Mississippi is stated, by an American agricultural journal, to have olive trees growing, which at five years from the cutting bore fruit, and were as large at that age as they usually are in Europe at eight years old. The olive then, it is added, will yield a fair crop for oil at four years from the nursery, and in eight years a full crop, or as much as in Europe at from fifteen to twenty years of age. The lands and climate there are stated to be as well adapted to the successful cultivation of the olive for oil, pickles, &c., as any part of Europe. Some hundreds of the trees are grown in South Carolina, and the owner expressed his conviction that this product would succeed well on the sea-coast of Carolina and Georgia. The frosts, though severe, did not destroy or injure them, and in one case, when the plant was supposed to be dead, and corn was planted in its stead, its roots sent out shoots. It is well known to be a tree of great longevity, even reaching to 1,000 or 1,200 years; so that, when once established it will produce crops for a great while afterwards. The expense of extracting the oil is also stated to be but trifling. The olive is of slow growth; trees 80 years of age measure only from 27 to 30 inches in circumference at the lower part of their trunks. An olive tree is mentioned by M. Decandolle as measuring above 23 feet in circumference, which, judging from the above inferences, may be safely estimated at 700 years old. Two other colossal olives are recorded, one at Hieres, measuring in circumference 36 feet, and one near Genoa, measuring 38 feet 2 inches. The produce in fruit and oil is regulated by the age of the trees, which are frequently little fortunes to their owners. One at Villefranche produces on an average, in good seasons, from 200 to 230 pounds of oil. The tree at Hieres, above mentioned, produces about 55 imperial gallons. The olive is found everywhere along the coast of Morocco, but particularly to the south. The trees are planted in rows, which form alleys, the more agreeable because the trees are large, round, and high in proportion. They take care to water them, the better to preserve the fruit. Oil of olives might be here plentifully extracted were taxation fixed and moderate; but such has been the variation it has undergone, that the culture of olives is so neglected as scarcely to produce oil sufficient for domestic consumption. Olive oil might form one of the most valuable articles of export from Morocco. It is strong, dark, and fit only for manufacturing purposes. This is, perhaps, not so much the fault of the olive as of the methods by which it is prepared. No care is taken in collecting the olives.—*Simmonds.*

Dr. Royle tells us that the Olive tree, ελαια of the Greeks, *Zait* of the Bible, and *Zaitoon* of the Arabs, is one of the most celebrated and useful of trees. The olive tree is usually small, evergreen, but of a dull aspect, wood hard. Leaves with short petioles, ovate-lanceolate or lanceolate, mucronate of a greyish green colour above, hoary beneath. Flowers white, in short axillary clusters. Cal. (2) small 4-toothed. Corol with short tube and 5-cleft limb (1). Stamens 2, a little exserted. Style short. Stigma (2) bifid segments emarginate. Ovary 2 celled, 2-seeded. Drupe (3) about the size of a damson, purple coloured, containing only one sharp-pointed nut.—A native probably of Asia, early cultivated in Syria and Greece. The varieties of the olive are numerous. The var. *longifolia* is chiefly cultivated in the S. of France and Italy, and the var. *latifolia* in Spain. - Esenb. and Eberm. 212. St and Ch. 15. The leaves and bark of the Olive tree have been employed; also a peculiar resinous exudation, called *Olicile* and *Olive gum*. And the bark as a substitute for Cinchona. The fruit of the Olive though esteemed even in its unripe state, as an article of the dessert, having been first steeped in an alkaline ley, and then preserved in salt and water, is chiefly valued on account of the bland fixed oil which is stored up in its outer fleshy part. This is obtained by at once bruising the nearly ripe fruit with moderate pressure in a mill (*Virgin Oil*), or by the aid of boiling water and greater pressure, or when fermentation has taken place in the olives collected in heaps, *ordinary* and inferior oils are thus obtained, the worst being employed only as lamp-oils or in the manufacture of Soap. The finest oils are produced near Aix, Montpellier, Nice, Genoa, Lucca, and Florence. It is also largely produced in the kingdom of Naples, and exported from Gallipoli, on the East coast of the Gulf of Taronta, whence it is commonly called Gallipoli Oil. Olive oil may be taken as the type of the *Fatty* or *Fixed*, called also *Expressed Oils*. It is of a pale yellow, or of a light yellowish-green colour, without smell when fresh, having a bland, somewhat sweetish, fatty taste. It is very limpid. Sp. Gr. 0·910 at 77°, insoluble in water, is readily dissolved by volatile oils, and by twice its bulk of Ether, but requires much more Alcohol. Exposed to the air it absorbs Oxygen and be-

comes rancid, but not drying like Linseed oil, is preferred for machinery. At 38° F. it begins to congeal, and is readily separated at 20° into two distinct bodies, of which one is fluid, called Elaine, or Oleine 72, and the other 28 per cent. solid, named Margarine from its pearly aspect. This is often deposited in jars and casks of the oil. Hyponitrous acid converts Olive Oil into a concrete mass from producing the oleaginous principle Elaidine, mentioned at p. 203. If this like other oils is heated with Alkaline solutions, or with the Oxide of Lead, great changes take place, as exemplified in the making of Soap, and of Lead Plaster, p. 161.

Tests.—Olive Oil is apt to be adulterated with poppy and other oils; these are distinguished by not congealing at the same temperature as olive oil, also by retaining air when shaken up, more readily than pure olive oil. The E. P. directs that "when carefully mixed with a twelfth of its volume of solution of Nitrate of Mercury, prepared as for the Unguentum Citrinum it becomes in three or four hours like a firm fat, without any separation of liquid oil." If 5 per cent. of any other oil be present, the consolidation is slower and less firm, but if there be 12 per cent, the foreign oil floats on the surface for several days. M. Gobley has invented an Elaiometer. (P. J. iii. 293.)

Action. Uses. Nutrient, Emollient, internally in irritant poisoning, externally relaxing, much employed for frictions and for embrocations, and to give consistence to Cerates, Ointments and Plasters: good application to the hair from not drying readily. In doses of ℥j. laxative added to enemata for its emollient effect, or to dislodge ascarides.—*Royle, p.* 476. There are several varieties of this plant, two of which have been long distinguished—the wild and the cultivated. The former is an evergreen shrub or low tree, with spiny branches and round twigs; the latter is a taller tree, without spines, and with four-angled twigs.—*Simmonds' Commercial Product, p.* 527.

(5841) OLEACEÆ, *Olivewarts*, a natural order of monopetalous Exogenous Plants, with a superior 2-celled ovary, a subvalvate corolla, two stamens, and a fruit with pendulous albuminous seeds. In the artificial collocations of natural orders to be found in books, these plants are usually stationed next *Jasminaceæ*, with which they have been even combined. It is however probable that they have really as much affinity with some of the monopetalous dicarpous orders. Lindley, in his 'Vegetable Kingdom,' arranges them in the Solanal Alliance, and gives their further affinities as with *Aceraceæ*, *Jasminaceæ*, and *Solanaceæ*. The species of the order best known in this country are, the Olive, or *Olea Europæa*; the Lilac, or *Syringa vulgaris*; the Evergreen Phillyrea of many forms; the privet, or *Ligustrum*; and the Fringe-Tree, or *Chionanthus*; all corresponding in habit and in sensible properties, which latter are very generally bitter and febrifugal. The bark of the Olive has been extensively used by the French instead of *Cinchona*, and the young fruits of the common Lilac form an infusion scarcely inferior to gentian. The most anomalous genus of the order is the Ash, which, in its most genuine form, has no petals, and in the division called *Ornus* has the petals present, but separate to the base. It is however, in all essential circumstances, the same in structure as the more regular genera, and its relation to the order has been ingeniously proved by the fact that the Olive and the Lilac will both live when grafted upon it. It is from the *Ornus*, or Flowering-Ash, that the bitter-sweet purgative called manna is secreted. The order has 24 genera and 130 species.—*Eng. Cyc.*

(5842) OLEASTER PLUM. Elæagnus conferta. This sour red plum makes very good tarts and jellies, and abounds in some parts of the Tenasserim jungle.—*Mason.*

(5843) OLIBANUM: Olibanum Indicum. —Gunda barosa—oleo-resinous product of Boswellia thurifera.—*Ben Phar.* Incense, Frankincense, Thus.

Looban, Arab.	Incenso Olibano, It.
Gunda barosa, Beng.	Looban Mal.
Avul Coondur, Duk.	Luban, Pers.
Encens, Fr.	Labuniya, Syr.
Incense, Koondur zuchir Guz. Hind.	Paranghi Sambrani, Tam.
	Weirauch, Ger.

Good Olibanum is, as met with in Bombay, in semi-transparent tears, of a light yellow colour, sometimes inclining to white; brittle, and adhesive when warm; when burnt the odour is very agreeable; its taste is bitterish, and somewhat pungent and aromatic. Olibanum has been celebrated from the earliest ages, and used in nearly all the religious ceremonies of antiquity. It is chiefly employed in fumigations, and in the ceremonies of the Greek and Catholic churches. It is imported into Bombay from the Persian Gulf; the superior or garbled qualities are re-exported to England and France, and the inferior or refuse kinds to China.—*Faulkner.* The source of this article is the Boswellia serrata or B. Thurifera.

(5844) *Boswellia*, a genus of balsamic plants belonging to the natural order Amyridaceæ. One of the species is believed by Colebrook to be the Ἄιβανος of Theophrastus, and the *Thurea virga* of the Romans. ('Asiatic Researches,' vol. ix.) *Eng. Cyc. page* 582. It appears that the gum-resin called olibanum is the frankincense that was used by the ancients in their religious ceremonies. Linnæus was of opinion that it was yielded by the Lycian juniper; but that plant is a native of the south of France as well as of the Levant, and the botanists of that country deny that any such substance is produced by their juniper. The Greeks obtained

their frankincense from Arabia. The Arabians call olibanum both Luban and Cunder; but as benzoin is most used at the present day for religious purposes, the Mohammedan writers of India on Materia Medica apply only the term Cundur to olibanum. This Cundur has been ascertained by Messrs. Colebrook, Hunter, and Roxburgh to be yielded by *Boswellia thurifera* or *Boswellia serrata*. It is a large timber-tree found in the mountainous parts of India, yielding a most fragrant resin from wounds made in the bark. Its leaves are pinnate, and consist of about ten pairs of hairy serrated oblong leaflets, each of which is from an inch to an inch and a half in length. The flowers are pale pink, small, and numerous. The calyx is 5-lobed, the corolla of 5-downy petals, the disk a fleshy crenelled cup, and the stamens 10, alternately shorter. The fruit is a 3-sided, 3-valved, 3-celled capsule, containing a single-winged pendulous seed in each cell. From this, Roxburgh distinguishes as a different species *Boswellia glabra*, a plant also yielding a resin which is used for incense and as pitch in some parts of India. It differs from the last in having no hairs on its leaves, in its leaflets being often toothless, and its flowers being panicled. A substance analogous to olibanum, and used in a similar way in various parts of the world, is procured from several different trees, such as, in America, the *Croton niteus* (Schwartz), *C. thurifer* (Kunth), *C. adipatus* (Kunth): in Columbia. *Bailleria nervifolia* (Kunth) yields the American frankincense; the *Amyris (Icica Tacamahaca*, Kunth) *ambrosiaca* (Linn), yields also the resin coumier, likewise called American frankincense. *Lætia apetale* (Jacq.) also yields a substance similar to frankincense. *Olibanum* occurs in commerce of two kinds, the Arabian and East Indian. The former kind is now seldom met with, and its origin is a subject of doubt; the latter is obtained from the tree above described, and to it we limit our remarks. There are two varieties or degrees of fineness of it, the best called 'olibanum electrum,' or 'in grains' sometimes called 'thus mannæ' or 'thus masculum': the other is termed 'olibanum commune,' or 'in sortis,' also fœmineum.' The first occurs in pieces varying from the size of a hazel-nut to that of a walnut, or larger, which are roundish or irregular in shape, of a light yellowish colour, varying to red or brown in some pieces, opaque or semi-transparent, the outside often covered with a white powder, and upon being pounded the whole becomes a white powder. It is very friable, and breaks with a dull, sometimes even, sometimes splintery fracture. The second sort is generally in larger pieces, mostly of a dirty-gray or fawn-colour, and intermingled with pieces of wood and other impurities.—*Engl. Cyc. p.* 583.

(5845) *Boswellia Glabra.*

Salaee, Hind. | Moræda, Tam.

A small tree; leaves pinnate, deciduous; flowers terminal, small, white with a red nectary, anthers yellow; yields the gum salai.

(5846) *Boswellia Serrata*, Stach. (B. thurifera, Colebr.); Roxb. Fl. Ind. 2. p. 383.

(5847) *Boswellia Thurifera*, Colebrooke, *As. Res.* xi. 317 xi. 158. Roxb. *Fl. Ind.* 383. Pereira, *Medical Gazette*, xx. 676.

Gunda barosa, Avul Kundoor, Vern. Looban, Duk. | Koonder Zuchir, Arab. Dup-salaee, Hind.

A tree with leaves pinnate as the last; grows on the hills of the Deccan. It is a native of the mountainous tracts of Central India, and very common in the Shahabad country. Dr. Hooker remarks, when speaking of this plant, we continued to ascend from Beleuppee in Behar to the height of 1360 feet, where I came upon a small forest of the Indian Olibanum (*Boswellia thurifera*), conspicuous from its pale bark, and spreading curved branches, leafy at their tips; its general appearance is a good deal like that of the mountain ash. The gum, celebrated throughout the East, was flowing abundantly from the trunk, very fragrant and transparent.—*Hooker Him. Jour. p.* 29. The *Salai, salaee*, tree, *Boswellia thurifera*, remarks Dr. Irvine, is plentiful in the Ajmeer hills: the gunda birosa is the prepared gum resin of this tree, and is similar in appearance and qualities to Venice turpentine. It is brought from Mewar, Harowtee and the Shekhawatee hills: and is considered stimulating: an oil is distilled from it, said to cure gonorhœa. It is used also in ointments: much used in painting and by the lakheries: one maund cost twelve rupees.—*Med. Top. of Ajmeer*: From the Shahabad country, Dr. O'Shaughnessy obtained fine specimens of the resinous products there called *sale gond or sale lassa*. At Chandalgur it is termed *gunda biroza*, and in the dry state *sukha biroza*. Dr. Hamilton however thought the English Olibanum to be the produce of an Amyris, partly because he could not find that the *sale* resin was used as incense by the Hindoos. The B. glabra and B. thurifera both furnish the Male frankincense of Dioscorides. The resin olibanum occurs in reddish or pale yellow tears, oval, oblong and obtuse, sometimes in dense, opaque, brittle masses. The gunda barosa of the bazars is soft, ductile, opaque, greenish and white. The odour is balsamic and resinous, especially while the resin is burning; the flavour balsamic, and rather bitter. The powder, citron yellow. It is frequently adulterated by dammer, sandarach, and other cheaper resins; when chewed, the hard variety softens, and dissolves partially in the saliva, which it renders white and emulsive. —*O'Shaughnessy.* The ointment from this is the late Mr. Muston's boil ointment, and is a very

useful application. It is an excellent substitute for the Elemi Ointment of the London Pharmacopœia.—*Beng. Phar, p.* 3838. According to Dr. Royle, the Indian is imported in chests chiefly from Bombay, also from Calcutta, but the place producing it is not well ascertained. Mr. Turnbull, of the Medical Service, many years since sent some resin of the *Salai* tree collected in the hills near Mirzapore, which in the London market was recognized as Olibanum. Mr. Colebrooke determined that *luban* or Olibanum is produced by a tree called *salai*. Dr. Royle also collected a very fragrant resin from the *saleh* tree of North-west India, which bears a very close resemblance to common Olibanum. This tree is *Boswellia glabra*, Roxb., the former is *B. thurifera* of Colebrooke, called *B. serrata* in many works; but as Messrs. Wight and Arnott say, "We dare not quote here *B. serrata*, Stack. extr. Bruc. p. 19, t. 3, the leaves being usually described as ovate, oblong, and acuminate." Both species were collected by Col. Sykes in the Deccan as the Olibanum-tree. Dr. O'Shaughnessy states that he has received fine specimens of Olibanum from the Shahabad district, where it is called *sale gond*, and at Chandalgur *gunda barosa*. This tree (Boswellia thurifera, fig. 55) grows to a large size in hilly situations, from the Coromandel coast to the central part of India it is much branched but bare of leaves in its lower parts, but these are crowded and alternate towards the ends of the branches, unequally pinnate. Leaflets oblong, obtuse, serrated, pubescent. Stipules none. Inflorescence in single axillary racemes near the ends of the branches, shorter than the leaves.—Flowers on short pedicels, of a pinkish white colour. Flowers bisexual. (v. 55. 1.) Calyx small, 5-toothed. Petals 5. obovate, tapering to the base, inserted under the margin of the disk; æstivation slightly imbricate. Disk surrounding the base of the ovary, cup-shaped, fleshy, crenulated. Stamens 10, inserted under the disk. Ovary sessile, 3-celled, with 2 ovules in each, attached to the axis. Style terminated by a capitate 3-lobed stigma. Fruit capsular, 3-angled, 3-celled, 3-valved, septicidal (splitting at the angles into valves). Seeds solitary in each cell, girded by a membranous wing. Cotyledons intricately folded, multifid. Indian Olibanum, which is now the most esteemed, is in roundish or oblong tears, of a reddish or a light yellow colour, usually covered with whitish powder from attrition of the pieces against each other, translucent within of a warm bitterish taste, and having a balsamic odour, especially when warmed or burnt. Sp. Gr. 1·22. Analysed by Dr. O'Shaughnessy, a fine specimen gave of Resin 37 parts, Volatile Oil 28 parts, Gum 4, Gluten 11, in 100 parts. But the quantity of Volatile Oil is necessarily much less when it has been exposed and become dry, as seen in commerce. Bracannot obtained only 8 per cent. of Oil, of Resin 56, Gum 30, matter like Gum 5·2, loss 0·8=100.

(5848) OLIBANUM AFRICAN, Africanischen Weihrauch. Ger.

Encens, Fr.

Imported into Vienia and Marseilles from Suez, and obtained from Arabia and the east coast of Africa, is mentioned by Dr. Pereira as African or Arabian Olibanum, and as occurring in smaller tears than the Indian variety, yellowish or reddish and intermixed with crystals of Carbonate of Lime. One kind of African Olibanum is no doubt produced on the hills of the Somali coast westward from Cape Guardafui, and carried to the Arabian coast chiefly by native boats from Maculla. This tree partially described by Capt. Kempthorne of the Indian Navy, has been identified by Mr. Bennett of the British Museum with *Ploslea floribunda* of Endlicher, but which appears to Dr. Royle to be nothing but a species of Boswellia, which he would therefore call *B. floribunda*. The specimens are covered with little resinous exudations, as are the leaves of a plant collected in the island of Socotra by Lt. Wellsted, which also appear to be those of a Boswellia. *Action. Uses.* Stimulant. Sometimes used in chronic affections of mucous membranes, but chiefly in plasters, and as a fumigation.—*Royle, p.* 338.

(5849) OLIVES.

Zeitoon, Arab.	Olivæ, Lat.
Olives, Fr.	Booa-minyak, Mal.
Oliven, Ger.	Zeitoon, Pers.
Zeitoon, Guz. Hind.	Azeitonas, Port.
Ulive, Olive, It.	Aceitunis, Sp.

The fruit of a tree (*Olea Europea*), a native of the South of Europe, Persia, and the North of Africa, and extensively cultivated in France, Spain, Italy, &c. Olives, when fresh, have a harsh, and extremely bitter taste; and they are eaten only after having been steeped for several days in a ley of wood ashes, and then pickled in a strong solution of muriate of soda. They are chiefly valued on account of the oil obtained from them; and are also eaten as an article of dessert. —*Faulkner.* See Olea. The fruit is perfectly oval, rounded at both ends, about one inch long, smooth, shining green, its sarcocarp fleshy, succulent, covering oval, oblong, rugose, pointed nut, marked with longitudinal furrows of ash colour; almond white, and compressed. Inodorous, taste rough, modified by salting.—*O'Sh.*

(5850) OLIVE, Chinese, the tree commonly called the Chinese olive is a species of Canarium, and the fruit gets this name from the resemblance it bears to the olive of Europe; It grows along with the Chinese date, a species of (zizyphus), which produces a fruit not unlike the date imported into England.—*Fortune's Wanderings, p.* 382.

(5851) OLIVE OIL, Lucca Oil, Salad Oil.

Huile de Olives, Fr.	Olio d Uliva. It.
Baumol, Ger.	Oleo-das-Azeitonas, Port
Zeytoon-ka-teil, Guz. Hind.	Aceite de Aceitunas, Sp.

The lightest of the fixed oils, is derived from the olive fruit. Olive oil being high priced, is frequently adulterated with cheaper kinds, sesamum oil (*Vern.* Gingelly oil) chiefly. In the countries of production, this oil is an important article of subsistence to all classes; and is also employed to burn in lamps. In Great Britain it is used in cooking and for salads, and considerable quantities are also employed in the making of fine soap, in the woollen manufactures, and in other arts. In medicine it is used as an emollient, and to form cerates and plasters. It is supposed that a portion of the large quantities of Gingelly oil exported from Bombay to France, after undergoing certain purifying processes are returned to India in the shape of olive oil.—*Faulkner.* See Olea. Olive oil is of pale yellow colour, greenish in one variety: is often adulterated with the oil of poppies. Poutet describes a test by which he states the adulteration may be detected; 8 parts of liquid nitrate of mercury when mixed with 92 parts of *pure* olive oil solidify completely in a few hours; should the oil contain even one-twentieth of the oil of poppies, a soft mass only is obtainable. These experiments are however only available in India during the nights of the cold season. The principal use of olive oil is as an aliment; it is also consumed extensively in soaps, cerates, liniments, plasters, &c. According to the mode of expression, the quality of the oil varies considerably; *virgin oil*, the product of the perfectly recent fruit, is of greenish colour, and highly esteemed; *common olive oil* results from the expression of the fruits after they have undergone a slight fermentation. It is yellow, sweet, and well suited for culinary purposes. The oils inferior to this are consumed almost exclusively in the fabrication of soap, and are obtained by subjecting to the press a second time the crushed fruits which have already yielded the first and second qualities of oil. The finest olives and the worst oil are produced in Spain. The oil of the Sesamum orientale, of the arachis, and of the poppy, are perfect substitutes for the olive oil for medicinal and pharmaceutical uses.—*O'Shaughnessy, p.* 432,433. Vegetable oils are in most cases extracted from the seeds of plants, but in the case of the olive, the best oil is contained in the pulpy part of the fruit, and this is carefully extracted before the seeds are subjected to pressure. The olive is a tree which grows luxuriantly in Italy, whence our chief supply of the oil is obtained; but it is not indigenous to that country, having been transmitted thither from its home in the east. Asia, the birthplace of civilization, was likewise the birthplace of the olive; and in the western world the tree followed the progress of peace, of which it is considered the symbol. The olives in Syria and the Holy Land are very numerous and of great age, springing up without culture in wild luxuriance. The olive-groves of Greece are likewise famed, and some of the Greek islands export large quantities of the oil. Olive oil is also to be obtained on the African coast, and in the south of France and Spain. The olive-tree is not very much unlike the English willow, and is frequently polarded in a similar manner. The scenery in that part of the Italy which may be called "the heel of the boot," is rendered monotonous by the immense olive-groves which cover the country. Throughout the whole of the two provinces Bari and Lecce, or La Terra d' Otranto, scarcely anything else is cultivated. The most celebrated port of these provinces is Gallipoli, which gives its name to the oil brought from an extensive district. Great part of the merit of Gallipoli oil arises from the facilities which that town possesses for keeping it pure and fresh after it is brought in from the country. These will be noticed presently, but we must first describe the very simple means employed to procure the oil. Olive-trees begin to bear at two years old, but are not in full bearing until after five or six years, when they become a sure source of wealth to their owners. They are of extreme longevity, and will bear luxuriant crops when the trunk is quite hollow. A tree of this description, whose empty shell scarcely supported it against the mountain storms, is stated to have produced in one year 240 English quarts of oil. Some years ago there was an olive-tree near Nice in a decaying state, which had been the wonder of that part of the country on account of its enormous size and great age. The lowest extremity of the trunk measured 38 feet, and one of the main branches 6½ feet in circumference. As far back as 1516 this tree was distinctly recorded as the oldest in the neighbourhood. In former years it has borne upwards of three hundred-weight of oil in one season, and so late as 1818 it produced two hundred weight. A celebrated olive-tree at Pescio was said to be 700 years old. These, however, are exceptional cases, and it appears probable that the majority of trees do not continue productive much above a century, unless great attention is bestowed upon them. The ingathering of the olives is performed in different ways. Some cultivators allow the fruit to attain complete ripeness and to drop from the trees. Others consider that the fully ripe fruit produces too fat an oil, and one which is liable to become rancid; they therfore gather it a little before it is ready to drop. Others again prefer gathering the fruit some little time before it is ripe, but the oil thus obtained is liable to be sharp

or bitter. The fruit is sometimes beaten off with poles, a very injurious plan for the trees. The olives likewise are bruised, and unless used directly, the oil obtained from them has a bad flavour. The more tedious process of hand-gathering is therefore to be greatly preferred. In order to obtain the finest description of oil, the ripe fruit is conveyed at once to the mill, or if unripe, it is allowed to lie for 24 or 48 hours in a dry place until it begins to wrinkle. For inferior oil or for soap, the olives are heaped up in storehouses, sometimes for months together, and lose much oil from fermentation, while that which remains is greatly deteriorated in flavour. With proper precautions, however, such as frequent turning of the heaps, leaving spaces for the air to circulate, and keeping the several gatherings distinct, much of this loss may be avoided. The crushing of the olives is effected in a mill of the simplest construction, consisting sometimes of a single mill stone, turning in a circular bed: at others, of two mill-stones, placed far enough apart not to crush the seeds The workmen remove the pulp when sufficiently crushed, and place it in bags or sacks, which are heaped up on the platform of a press. This is also of a very rude description, and gives but a slow and feeble pressure. The oil which first exudes from the olives (supposing them to be of good quality) is a fine pure oil, much sought after for the supply of the table. It is known in commerce as *virgin salad oil*. After this is all extracted, there yet remains a considerable quantity so mixed with vegetable albumen that it cannot flow out. The bags of pulp are therefore lifted up, between each is poured a certain quantity of boiling water. This causes the pulp to swell by the absorption of the water: the albumen coagulates, and the more fluid oil flows freely. Still a certain quantity of oil remains among the refuse, and this is subjected to further treatment in separate workshops, the resulting oil being only fit for soap-making. The imperfection of the former process alone renders these latter ones necessary so that a large amount of time and labour is thus unnecessarily expended. As soon as the first run of fine oil is obtained from the olives, it is conveyed in jars or skins to a reservoir, and on the nature of this reservoir much of its after value depends. The town and report of Gallipoli owe much of their celebrity to the circumstance of the former being built on a rocky island, easily excavated into caverns and cisterns where the oil soon clarifies, and can be long preserved without becoming rancid. A Gallipolitan oil-house is described as being the ground-floor of a dwelling-house, in the stone basement of which 4, 6, or more circular holes are seen, about 2 feet in diameter, resembling the mouth of wells. These are the openings to separate cisterns reserved for different qualities of oil. The oil brought in a turbid state to these excellent reservoirs soon becomes bright and yellow, and in some cases may be kept for a period of 7 years. It is carried thither in sheep or goat-skins, generally on the backs of mules, and when it is to be shipped, it is drawn off from the cisterns into skins, and carried on men's shoulders to a house on the sea-shore, where there is a large open basin capable of containing a given quantity, and of measuring the liquid, and into that the porters empty their skins as they arrive. A tube leads from the basin to a large cock on the outside of the house. Under this cock are placed casks of various sizes, and the oil is thus conveniently drawn off into them. Coopers are at hand to close the casks securely, after which they are rolled down to the beach, and being fastened, several together, by ropes, they are attached to a boat, which tows them through the water to the ship's side. The number of persons employed in all these operations is very great, and their cheerfulness, frequently exhibited by singing in concert, gives a very lively effect to the whole scene. The produce of a full crop of oil, in the province of which Gallipoli forms the chief outlet, was, in 1843, nearly 22,000 tuns. Fine *Spanish soap*, known in England as *Castile soap*, is made of olive oil mixed with alkalies. A similar manufacture is carried on at Marseilles, which has a large export trade in soap. Olive oil is largely used in Greece, Italy, Spain, and France, as an article of food, and in medicine, and the arts. It is extensively used in England, especially in the woollen manufacture. The fine oil, called *Florence oil*, used for culinary purposes, is brought from Leghorn in chests containing 30 bottles, or 4 English gallons. Oil of olives varies in colour from greenish to pale yellow. A little above the freezing point of water it begins to deposit some white grains of stearine. At 22°, it deposits 28 per cent of its weight of stearine.—*Tomlinson.*

(5852) OLIVE, OLEA ATTENUATA. Wallich found a species of olive tree on the banks of the Salwen, but from which no oil is made—*Mason.*

(5853) OLIVE PLANTS, grow well at Dapoorie which is 1900 above the Sea.—*Spry's Suggestions, p.* 38.

(5854) OLIVE TREE OF CHINA; OLEA FRAGRANS. (Thunberg, Fl. Jap. t. 2), is a native of China and Japan; its flowers evolve a most delicious odour, and are sometimes used to perfume teas.—*O'Shaughnessy, p.* 433.

(5855) OLIVE WOOD. The matured wood of the olive is hard, compact, and reddish in colour. It takes a fine gloss, and is made into snuff boxes, and trinkets. *Waterston.* —*Faulkner.*

(5856) OM MANI PADMI OM. A Buddhist prayer, in Sikkim and Thibet. Is an in-

vocation of Sakkya, who is usually represented holding a lotus flower with a jewel in it: Its meaning is, Hail to him of the lotus and jewel. —*Hooker, Vol.* I. *p.* 229. Everywhere at Tumlong, in an oratory, the lotus, the mani, and the chirki (or wheel with three rays, emblematic of the Boodhist Trinity), were introduced; "Om Mani Padmi om" in gilt letters, adorned the projecting end of every beam, and the Chinese "cloud messenger," or winged dragon, floated in azure and gold along the capitals and beams, amongst scrolls and groups of flowers. At one end was a sitting figure of Gorucknath in Lama robes, surrounded by a glory, with mitre and beads.—*Hooker, Him. Jour. Vol.* II. p. 194. A mythical animal with a dog's head and blood-red spot over the forehead was not uncommon in this chapel, and is also seen in the Sikkim temples and throughout Tibet. Ermann, in his Siberian Travels, mentions it as occurring in the Khampa Lama's temple at Maimaochin; he conjectures it to have been the Cyclops of the Greeks, which according to the Homeric myth had a mark on the forehead, instead of an eye. The glory surrounding the heads of Tibetan deities is also alluded to by Ermann, who recognises in it the Nimbus of the ancients, used to protect the heads of statues from the weather, and from being soiled by birds; and adds that the glory of the ancient masters in painting was no doubt introduced into the Byzantine school from the Boodhists.—*Hooker, Him. Jour. Vol* II. p. 195.

(5857) OMMASTREPHES, a genus of Cuttle-Fishes belonging to the family *Teuthidæ*. The Cuttel-Fishes of this genus closely resemble those belonging to *Loligo*. Besides other characters they may generally be distinguished by the short rhomboidal termination of the body, formed by the fins, combined with the hinder extremity.

(5858) OMUM WATER, is the distilled water from Bishop's weed seed. It is a useful carminative and largely used for children in Madras. At the Madras Exhibition of 1855, the late *Mr. Gay's* specimens of various pharmaceutical preparations, including *Omum Water, crystallized sugar of Omum*, &c. were considered creditable, and deserving of notice.—*Madras E. J. R.*

(5859) ONDATRA (Lacepede), a genus of Mammalian animals belonging to the family *Castoridæ*. Ondathra is the native name of the Musquash, or musk-rat, which has been adopted as its generic designation. The only species of this genus is the Musquash of America. Of this animal Sir John Richardson gives the following synonyms:—Rat-Musque of Sagard Theodat; *Castor Zibethicus* of Linnæus; L'Ondatra of Buffon; Musk-Rat of Lawson; Musk-Beaver of Pennant; *Mus Zibethicus* of Linnæus and Gmelin; *Fiber Zibethicus* of Sabine and Harlan; Musk-Rat of Godman; Musquash, Watsuss, or Wachusk, also Peesquaw-Tupeyew (the animal that sits on the ice in a round form), of the Cree Indians. In a tract which has for its title, 'A Perfect Description of Virginia,' 1649, we find among the "Beasts great and small . . . a Muske-Rat, so called for his great sweetnesse and shape."

Dental Formula:—Incisors, $\frac{2}{2}$; Molars, $\frac{3-3}{3-3}$ = 16.

The head is short. Body thick and rather flat; legs very short, hind feet large, not webbed. Dark umber-brown above; sides, anterior part of belly, middle of breast, lateral part of neck and cheeks, shining yellowish-brown; chin, throat, sides of the chest, and posterior part of the abdomen, ash-gray; tail compressed, convex on the sides, with its acute edges in a vertical plane, covered with a thin sleek coat of short hairs, which allow a number of small roundish scales, well separated from each other, and which as well as the hair are dusky-brown, to appear through them; acute margins of the tail (which is rather thicker in the middle than at the root, and tapers gradually from its middle to its extremity, which is not acute) covered with a close line of longer hairs dark-brown on the upper edge and soiled white on the under one. Length of head and body 14 inches; of the tail, 8 inches 6 lines. The fur, which much resembles that of the beaver, but is shorter, resists the water during the life of the animal, but is easily wetted. Charlevoix states that the Musk-Rat takes the field in March, at which time its food consists of bits of wood, which it peels before it eats them. After the dissolving of the snows he says that it lives upon the roots of nettles and afterwards on the stalks and leaves of that plant. In summer it feeds on strawberries, &c. to which succeed the autumnal fruits. During this time he states that the male and female are rarely seen asunder. According to the same author they separate in winter, when each takes up its lodgings apart in some hole or in the hollow of a tree, without any provision; and the Indians declared that not the least morsel of anything is eaten by them whilst the cold continues. "They likewise," adds Charlevoix, "build cabins nearly in the form of those of the beavers, but far from being so well executed. As to their place of abode, it is always by the water side, so that they have no need to build causeways....The flesh is tolerable good eating, except in the time of rut, at which season it is impossible to cure it of a relish of musk, which is far from being as agreeable to the taste as it is to the scent." The habitations of the Musquashes, and the mode of hunting them, are thus described by Sir John Richardson:—"In the autumn, before the shallow lakes and swamps freeze over, the Musquash builds its house of mud, giving it a coni-

cal form, and a sufficient base to raise the chamber above the water. The chosen spot is generally amongst long grass, which is incorporated with the walls of the house, from the mud being deposited amongst it; but the animal does not appear to make any kind of composition or mortar by tempering the mud and grass together There is however a dry bed of grass deposited in the chamber. The entrance is under water. When ice forms over the surface of the swamp the Musquash makes breathing holes through it, and protects them from the frost by a covering of mud. In severe winters however these holes freeze up in spite of their coverings, and many of the animals die. It is to be remarked that the small grassy lakes selected by the Musquash for its residence are never so firmly frozen nor covered with such thick ice as deeper and clearer water. The Indians kill these animals by spearing them through the walls of their houses, making their approach with great caution, for the Musquashes take to the water when alarmed by a sound on the ice. An experienced hunter is so well acquainted with the direction of the chamber and the position in which its inmates lie, that he can transfix four or five at a time. As soon as, from the motion of the spear, it is evident that the animal is struck, the house is broken down, and it is taken out. The principal seasons for taking the Musquash are—the autumn before the snow falls, and the spring after it has disappeared but while the ice is still entire. In the winter time the depth of snow prevents the houses and breathing-holes from being seen. One of the first operations of the hunter is to stop all the holes with the exception of one, at which he stations himself to spear the animals that have escaped being struck in their houses, and come hither to breathe. In the summer the Musquash burrows in the banks of the lakes, making branched canals many yards in extent, and forming its nest in a chamber at the extremity, in which the young are brought forth. When its house is attacked in the autumn it retreats to these passages, but in the spring they are frozen up. The Musquash is a watchful but not a very shy animal. It will come very near to a boat or canoe, but dives instantly on perceiving the flash of a gun. It may be frequently seen sitting on the shores of small muddy islands in a rounded form, and not easily to be distinguished from a piece of earth, until on the approach of danger it suddenly plunges into the water. In the act of diving, when surprised, it gives a smart blow to the water with its tail." Sir John Richardson records three varieties besides that above described:—

1. The Black Musquash, rare.

2. The Pied Musquash, with dark blackish-brown patches on a white ground.

3. The White Musquash (*Fiber Zibethicus albus*, Sabine). This albino is not unfrequent.

According to Hearne, the Musquash is easily tamed, soon becomes attached, and is cleanly and playful. The fur is used in hat making, and upwards of one million of skins are imported into this country.—*Eng. Cyc.*

(5860) ONONIS (from ὄνος, an ass, and ὄνημι, to delight, some of the species being said to be grateful to asses), a genus of Plants belonging to the natural order *Leguminosæ*. It has a 5-cleft campanulate calyx, narrow segments, the lower ones longer. The keel is beaked, the style filiform and ascending, the stigma terminal and subcapitate. There are 107 species of this genus described, but none of them are used in medicine or the arts. They are chiefly natives of Europe; about twelve species are found in Africa, and a few on the coast of Asia. (Babington, *Manual of British Botany.*)—*Eng. Cyc.*

(5861) ONION: Allium Cepa. Lin.; Bulbus, D. The Bulb of the Common Onion.

Bussel, Arab.	Bavangmira, Mal.
Bawung, Bali.	Peeaz, Pers.
Kembally, Can.	Cebola, Port.
Loono, Cyng.	Luk, Rus.
Oignon, Fr.	Palandu, Lafarka, Sukundaka, Sans.
Zwiebel, Ger.	Cebolla, Sp.
Khanda, Peeaz, Guz.	Venggayum, Tam.
Peeaz, Hind.	Woolligudda. Tel.
Cipolla, It.	
Braugbang, Jav.	

The Onion is the κρομμυον of the Greeks, *Busl* of the Arabs, and the *Betzulim* of Numbers, xi. 12. Biennial. Bulb simple, roundish, invested with shining, thin, dry membrane. Stem 1—2 feet high, fistular, leafy, and often ventricose at the base. Leaves glaucous, distichous, fistular, terete-acute, shorter than the stem. Spathe reflexed. Umbels large, regular, globose, many-flowered, not bulbiferous. Flowers whitish or greenish, the segments with a green keel, linear-elliptic, obtuse, shorter than the stamens.—Cultivated in gardens in Europe; flowers in July. Probably a native of the Persian region.—Fl. Græca, t. 326.—*Royle.* These well-known bulbous plants are extensively cultivated for pickling, culinary purposes, &c. They vary in size, flavour, and quality, according to the kind, soil, climate, and manner of cultivation. Those most esteemed in the Bombay Presidency are the Surat onions.—*Faulkner.* This vegetable is common all over India, and is sown broad-cast. When about six inches high it is pricked out into beds six fingers' breadth apart; they are sown at almost all seasons of the year, and go to seed without difficulty.—*Riddell.* This is a favorite pot vegetable of the Natives of India, and is a constant ingredient in all their curries, pollaos, &c. &c. &c.—*Ainslie, p.* 246. The common English onion is sometimes cultivated in Tenasserim, but the principal part of the onions seen in the bazars are brought from Rangoon, and it is believed are of a different species.—*Mason.*

(5862) ONOSMA, (from ὄνος, an ass, and ὀσμη, smell; grateful to the ass), a genus of Plants belonging to the natural order *Boraginaceæ*. It has a 5-parted calyx, a tubularly campanulate corolla, and a naked throat. The anthers are sagittate, and connected together by the bases of the lobes. The nuts are ovate, strong, and fixed to the bottom of the calyx, unperforated at the base. The species are small scabrous canescent plants, with crowded lanceolate or linear leaves, and terminal racemes of large yellow secund and usually drooping flowers. —*Eng. Cyc.*

(5863) ONOSMA EMODI, has lanceolate triple-nerved leaves, less hairy beneath, terminal solitary racemes, linear bracts, not half so long as the flowers: the calyx is 5-cornered with ovate segments a ventricose 5-keeled corolla contracted towards the mouth, and the anthers longer than the filaments. It is a native of Nepaul, in Gosaingsthan, where it is called by the natives Mahairanga. The root is branched, of a dark purple colour, and is used in dyeing. *Eng. Cyc.*

(5864) ONOSMA MACROCEPHALA, Onosma Bracteatum, Royle, is officinal in Cashmere, and grows plentifully on the Himalayas; namely, on the Hindokoosh near the Punjab-road, via Peembur to Cashmere. Flowerstem and root, are both of them efficacious and useful in medicine. —*Honigberger, p.* 316.

(5865) ONYX.

Onix, Onice, Fr.	Onyx, Lat.
Onyx, Ger.	Onique, Sp.

Onyx, one of the inferior gems, the silicious particles are arranged in alternating horizontal layers of opaque white and translucent blue, gray, or brown, and because these have a resemblance to the marks on the human nail, the stone was called from the Greek word for nail, ὄνυξ. It was known to the ancients, and was employed by them, as it is now, for those beautiful gems called Cameos, the figure being cut out of the opaque white, the dark part forming the ground, or the contrary. It is most valuable, when the contrast of colours is strong, and when the layer is thick enough to give a high relief to the object to be engraved. In the royal library at Paris there is an antique cameo cut out of an onyx with four layers, representing the apotheosis of Augustus, eleven inches by nine, which is supposed to be the finest in existence. Agates with an onyx structure are not uncommon, particularly among calcedonies, but the finest are brought from India. Cameos are sold at Rome, which are made from a thick shell, having different coloured layers like an onyx.—*Eng. Cyc.*

(5866) OOD BUTTEE, pastils of Wood Aloes, sandal wood, benjamin: Lichen rotundatus, the Patchouli, foliated gypsum; Talisputree (Flacourtia cataphracta) gum mastich, sugar-candy and gum, pounded fine and formed into pastils: They are made in every large town and burut for the fragrance they give out.

(5867) OOD, IN INDIA. Is the name applied to Benjamin; and in Persia, to Wood Aloes.

(5868) OOLIES. Are bars of steel, fabricated from Vuttoms.

(5869) OONDEY OIL. Its source is not known, at Madras: is supposed to be a Fish oil manufactured at Malabar.

(5870) OOROOPA. Is the Malayalam name of a tree, which the Natives of that country prefer to take for building ships, being more durable and close grained.—*Ainslie. Rohde M. S. S.*

(5871) OOSARA-REWAND. Stalagmitis Gamboogioides. Is real gamboge, and is imported via Pali; considered and used as a violent cathartic, the punsaris suppose it to be the extract of the Mirabilis jalapa root, the dose given is sixteen grains: one seer costs four rupees —*Gen. Med. Top. p.* 118.

(5872) OOTRUM FIBRE. Demia extensa. Is a promising substitute for flax. The plant grows in the Madras Presidency.

(5873) OOTUNGUN. A seed used in medicine procurable in all Indian Bazars, obtained, according to Dr. Royle, from a species of Urtica. *Honigberger.*

(5874) OPAL.

Opale, Fr.	Opalus, Lat.
Opal, Ger.	Opala, Pol.
Opalo, It.	Opalo, Piedrais, Sp.

Of this mineral which is essentially a hydrate of silica, there are mentioned by Mr. Brooke, in the 'Encyclopædia Metropolitana,' eleven varieties, and nearly as many are described by Phillips.

Precious Opal or *Noble Opal.*—This mineral is white, bluish, or yellowish-white, and exhibits a beautiful variety or play of colours, as blue green, yellow, and red, several of which appear together. Fracture conchoidal, with a vitreous or resinous lustre; it is easily broken, but scratches glass. Specific gravity 2·06 to 2·09. Infusible by the blow-pipe, but becomes opaque and loses water. The most beautiful specimens occur in Hungary, but it has also been found in Saxony, South America, &c. Analysis of the Hungarian opal by Klaproth:—

Silica	90
Water	10
	—100

Fire-Opal.—In this the internal reflection is bright red. It occurs with the Precious Opal in Hungary, and has also been found in Cornwall.

Hydrophane.—It is usually opaque, but is rendered transparent, and exhibits the iridescent colours of the Precious Opal by immersion in water. According to klaproth it contains a little alumina in addition to silica and water.

Common Opal.—This is of various shades of colour, as white, green, yellow, and red; but is entirely destitute of the play of colours exhibited by the Noble Opal. In other properties they greatly resemble each other. It is stated to contain a little oxide of iron mixed with the silica and water. It is found chiefly in Hungary and Saxony, but specimens have also been produced in Cornwall and in the Dekhan.

Semi-Opal—This is more opaque than the Common Opal, and is dull. It occurs either white, gray, yellow, brown, or green. It is found in the same places as the foregoing.

Wood-Opal, so called from its showing the woody structure. It occurs of several tints of white, gray, brown, and black. It is generally harder than the Semi Opal, but does not materially differ from it in other properties. It occurs in Hungary, in Transylvania, and in Madura.

Cacholong is white opaque opal; harder than the Common Opal; dull; brittle; fracture flat conchoidal. Specific gravity 2·2. Infusible before the blow-pipe. It is found on the banks of the river Cach in Bucharia, in loose masses. It occurs also in the Faroe Islands, Greenland, and Iceland.

Opal Jasper, Ferruginous Opal.—Opaque, or but feebly transparent on the edges. Colour generally deep shades of red, yellow, and gray. Fracture flat conchoidal. It appears to be a silicate of iron with water. It occurs in Hungary, Siberia, and Madura. Klaproth's analysis of a variety from Telkebanya gave—

Silica	43·5
Oxide of Iron	47·0
Water	7·5
Eng. Cyc.	——98·0

(5875) OPERCULUM (Malacology), the plate or pieces which protect the apertures or exposed parts of certain Molluscs. In many of the Testaceous Gastropods it becomes a cover or door, which fits the aperture of the shell more or less accurately when the animal has retired within it. Opercula of this kind vary much in structure and shape. Thus they are sometimes horny, as in *Trochus* and *Murex*; sometimes shelly, nay almost stony as in *Turbo*; and in construction they are for the most part either spiral, concentric, or unguiculated. In Botany this term is chiefly used for the cap which forms the upper extremity of the theca, or sporangium, of a moss, covering over the peristome, and usually falling off when the spores are ready for dispersion. It has also been applied to the lid which covers in the Pitcher of *Nepenthes*, where it is the lobe of a modified leaf —*Eng. Cyc.*

(5876) OPHELIA. Of this genus Wight gives Ophelia corymbosa, 1329-30; elatior, 1330 elegans, 1331; Grisebachiana, 1330; minor, 1332

(5877) OPHELIA ANGUSTIFOLIA, O. PHELIA ANGUSTIFOLIA, Don, (SWERTIA ROYLE) Nat. Ord. Gentianeæ.

Puharee Cheretta, Hind.

This species has long been used as a bitter tonic. Ind. An. No. 6. It is called Puharee chiretta in the hills, and is substituted for the true kind.—*O'Shaughnessy, p.* 460. *Exacum tetragonum* is similarly named *Ooda chiretta*, or purple chiretta.—*O'Shaughnessy, p.* 460.

(5878) OPHELIA CHIRATA, Grisb. Chiretta Herb and Root. (*Agathotes Chirayta*, Don.) Chiretta, *Tetrand*: *Monog* Linn. The bitter called *Chiretta*, or *Chiracta*, is as universally employed throughout Southern Asia as Gentian is in Europe. It has long been known to the Hindoos, but there is no reason to suppose it to be the *Calamus aromaticus* of the ancients. (*v.* Himal. Bot. p. 277). The first English account is that of Dr. Fleming (in Asiat. Res. xi. p. 167), who referred it to the genus Gentiana, others to Swertia, and the late Prof. Don to Agathotes; Grisebach now refers it to Ophelia. It is often confounded with another powerful Indian bitter, that is, Creyat or Justicia paniculata. But there are several plants closely allied to the Chiretta, which are used for the same purposes, as stated in Him. Bot. p. 277. Thus, *Ophelia* (*Swertia*, Wall.) *angustifolia*, Don, is so in Northern India and called *puharee*, (*i. e.* hill) *chiretta*, to distinguish it from the true or *dukhunee* (southern) *chiretta*. This is obtained from Nepal. *Exacum tetragonum* is called *ooda* (that is, purple) *chiretta*. Ophelia chirata is an annual, of from 2—3 feet high, with a single, straight, round, smooth stem. Branches generally decussated, nearly erect. Leaves opposite, amplexicaul, lanceolate-acute, smooth, 5—7-nerved. Flowers numerous, stalked, upper half of the plant forming elegant decussated umbel-like cymes, with 2 bracts at each division. Calyx 4-cleft, with sublanceolate persistent divisions, shorter than the corolla. Corol yellow, rotate, limb 4-parted, spreading, whithering in æstivation, twisted to the right, with 2 glandular hollows protected by a fringed scale upon each segment. Stamens 4; filaments subulate, shortly connected at the base; anthers clover at the base. Style single. Stigma large, 2-lobed. Capsules conical, rather shorter than the permanent calyx and corol, 1-celled, 2-valved, opening a little at the apex. Seeds numerous, affixed to two receptacles adhering to the sides of the valves. Grows in theHimalaya mountains, o

which Nepal is one of the valleys.—Wall, Pl. As. Rar. 3. p. 33. t. 252.

Chiretta is met with in a dried state, tied up in bundles, with its long slender stems of a brownish colour, having the roots attached, and which have been taken up when the plant was in flower. The whole plant is bitter. Analysed by MM. Bousil and Lassaigne, they yielded a Resin, a yellow Bitter substance, a yellow colouring matter, Gum, Malic acid, Salts of Potash; and of Lime, and traces of Oxide of Iron. Mr. Battley states that it contains—1. A free Acid. 2. A very Bitter Extractive and Resinous matter, and much Gum. 3. Muriate and Sulphate of Lime and of Potash; also, that the Spirituous Extract is more aromatic than that of Gentiana lutea, but that the extractive and the gum are in larger proportion in the latter. Water and Spirit take up its active properties.

Action. Uses. Bitter Tonic; Stomachic in Dyspepsia or as a Tonic in Convalescence; either cold or hot infusion; the former is lighter, and well suited to Dyspeptics, and not so apt to create nausea in a hot climate. Sometimes a little Orange-peel or Cardamom is added. A Tincture made as that of Gentian (or ℥ ij. to Proof Spirit (℥ xvj.), like other bitters, is best taken half an hour before meals.—*Royle.*

(5879) OPHELIA ELEGANS, Wight. Grows plentifully in several parts of the Madras Presidency, is considered febrifuge by the Native physicians who prefer it to the Himalayan Chiretta. It grows plentifully in the Jeypore Zemindary of Vizagapatam, and is annually exported, as *Silaras* or *Selajit*, to the value of about Rupees 2,500. The infusion of O. elegans has a powerful bitterness.—*Cleghorn.* "Ophelia elegans," (vide Wight Icon. t 1031.) is closely allied to, and greatly resembles chiretta—the native name is *Salaras* or *Salajit*: the stalks are sold bound together in bundles about one foot long, and a little thicker than a man's arm. The drug is exceedingly cheap, and the amount exported is considerable: to what extent it is employed, is difficult to ascertain, as it is confounded in the bazar with "chiretta."—*M. E. J. R.* This species of ophelia is common on the Pulney Hills in Southern India, also in Vizagapatam, and the plant has long been used as a bitter tonic.—*Med. An. No.* 6.

(5880) OPHIDIA, an order of Reptiles without feet, and consequently, as Cuvier observes, more deserving the name of Reptiles than any other order. According to Cuvier, the order *Ophidia* consists of the genus *Anguis* [Blindworm], of True Serpents, and Naked Serpents. Cuvier's second family, or that of the True Serpents, comprehends the genera which have no sternum nor any vestige of a shoulder-blade, but whose ribs still embrace a great part of the circumference of the trunk, and the body of whose vertebræ are also articulated by means of a convex surface which is received into a socket or concavity of that vertebra which succeeds it. They want the third eyelid and the tympanum; but the ossiculum auditus exists under the skin, and its shaft or handle (so to speak) passes behind the tympanic bone. Many have vestiges of a posterior member under the skin, and the extremity of this rudiment of a limb shows itself externally in the form of a small hook. [Boidæ.] Those serpents to which the names of Doubles Marcheurs, or *Amphisbænidæ* [Amphisbæna; Typhlops], have been given, have the lower jaw carried, as in the Tortoises [Chelonia] and Lizards [Sauria], by a tympanic bone which is articulated directly with the cranium, the two branches of that jaw soldered anteriorly, and those of the upper jaw fixed to the cranium and the intermaxillary bone, so that their mouth cannot be dilated, as in Cuvier's next tribe (the serpents properly so called), and their head is of uniform size with their body; a form and structure which enable them to make progress equally well in both directions, head or tail foremost. The bony frame of the orbit is incomplete backwards, and their eye is very small. Their body is covered with scales, the anus very near its extremity, the trachea long, and the heart placed very far backwards. Of this tribe no venomous species are known. The Serpents, properly so called, have the tympanic bone, or pedicle of the lower jaw, moveable, and nearly always suspended to another bone analogous to the mastoidian, attached to the cranium by muscles and ligaments which permit its mobility: the branches of this jaw are not united to each other except by ligaments, nor are those of the upper jaw united to the intermaxillary bone in any other manner, so that they can be more or less separated: a conformation which gives these animals the power of dilating their mouth to such an extent as to enable them to swallow bodies larger than themselves. Their palatine arches participate in this mobility, and are armed with pointed teeth curved backwards—the most marked and constant character of this tribe. Their trachea is very long; their heart situated very far backwards; and the greater number have only one very long lung, with the vestige of a second. These serpents, says Cuvier, in continuation, are divided into venomous and non-venomous; and the former are subdivided into venomous with many maxillary teeth, and venomous with isolated fangs. In the non-venomous, the branches of the upper jaws are furnished throughout their length, as well as those of the lower jaw and of the palatine branches, with fixed teeth which are not pierced; there are therefore four nearly equal rows of these teeth in the upper part of the mouth, and two in the lower. [Boidæ.] Those which have the mastoidian bones comprised in

the cranium, the orbit incomplete backwards, and the tongue thick and short, much resemble the *Amphisbænidæ* in the cylindrical form of their head and body, as I have, Cuvier observes, been induced to the Orvets [ORVET], in consequence of the smallness of their scales. The Venomous Serpents with isolated fangs present a very peculiar structure in their organs of manducation. Their superior maxillary bones are very small, carried on a long pedicle analogous to the external pterygoid apophysis of the sphenoid bone, and very moveable: here is fixed a pointed tooth, pierced with a small canal which gives issue to a liquor secreted by a considerable gland situated under the eye. It is this liquor which, when shed into the wound made by the bite of the serpent, carries havock into the body of the wounded animal, and produces effects more or less fatal according to the species which has inflicted the wound. This fang is concealed in a fold of the gum when the serpent does not wish to use it; and there are behind it many germs destined to fix themselves in their turn, in order to replace it if it should be broken in the wound it makes. Naturalists, Cuvier remarks, have named these teeth crochets mobiles, or moveable fangs: but it is, properly speaking, the maxillary bone that moves: that bone carries no other teeth, so that, in the Venomous Serpents, only two rows of palatine teeth are seen in the roof of the mouth. All the venomous species bring forth their young alive, in consequence of the egg being hatched internally before it is laid, whence their general name of Vipers, a contraction of *Vivipares*. These deadly serpents with isolated fangs, though they present external characters of the same nature as the preceding group, have, the greater number of them at least, very dilatable jaws and a very extensible tongue. Their head, wide behind, has generally a ferocious aspect, which announces in some degree their malevolent nature. [VIPERIDÆ.] A third tribe has the jaws organised and armed nearly as in the Non-Venomous Serpents, but the species have the first of their maxillary teeth greater than the others, and pierced so as to conduct the venom in the same manner as is effected in the Venomous Serpents with isolated fangs. Such are the *Bungari* and *Hydri*. [HYDRIDÆ; PELAMYS]. The serpents, with one exception (*Deirodon*, to which we shall presently more particularly call attention), subsist on living prey; and, whether non-venomous or venomous, have their teeth, as might be expected, admirably constructed and arranged for the purpose of securing their prey and assisting in deglutition. Professor Owen, in his valuable and copiously-illustrated 'Odontography,' observes that the order *Ophidia*, as it is characterised in the system of Cuvier, requires to be divided into two sections according to the nature of the food and the consequent modification of the jaws and teeth. Certain species, he observes, which subsist on worms, insects, and other small invertebrate animals, have the tympanic pedicle of the lower jaw immediately and immoveably articulated to the walls of the cranium; the lateral branches of the lower jaw are fixed together at the symphysis, and are opposed by the usual vertical movement to a similarly complete maxillary arch above: these, as we have above seen, belong to the genera *Amphisbæna* and *Anguis*, Linn. The rest of the Ophidians, observes the Professor, which form the typical members, and by far the greatest proportion of the order, prey upon living animals, frequently of much greater diameter than their own, and the maxillary apparatus is, as we have also above seen, conformably and peculiarly modified to permit of the requisite distention of the soft parts surrounding the mouth and the transmission of the prey to the digestive cavity. But the mechanism by means of which this distention is accomplished, and which is in fact a dislocation of adapted parts which return to their original positions when the act of deglutition is accomplished, requires, to be well understood, a more particular description than the general account above given, and we proceed to that presented by Professor Owen, as the best and clearest known to us. The two superior maxillary bones have, he observes, their anterior extremities joined by an elastic and yielding fibrous tissue with the small and single intermaxillary bone: the symphysial extremities of the lower maxillary rami are connected together by a similar tissue, allowing of a still wider lateral separation. The opposite or posterior extremity of each ramus is articulated to a long and moveable vertical pedicle, formed by the tympanic or quadrate bone, which is itself attached to the extremity of a horizontal pedicle formed by the mastoid bone, so connected as also to allow of certain yielding movement upon the cranium. The palatine and pterygoid bones have similarly loose and moveable articulations, and concur with the other dentigerous bones of the mouth in yielding to the pressure of large bodies with which the teeth may have grappled. Professor Owen first describes the dental peculiarities of the true serpents, which, as he remarks, swallow their food whole, whether they prey on living animals, as is the case in almost every species, or feed on the eggs of birds, as does *Deirodon scaber*, Owen (*Coluber scaber* Linn). With the exception of this and some congeneric species, in which the teeth of the ordinary bones of the mouth are so minute as to have been deemed wanting, the maxillary and premandibular bones in all true Ophidians are, he observes, formidably armed with sharp pointed teeth; there is on each side of the palate a row of similar teeth supported by the palatine

and pterygoid bones: in the great Pythons and some species of *Boa*, he adds, the intermaxillary bones also support teeth. But whatever be their position, all the teeth, according to the Professor, present a simple conical form, the cone being long, slender, and terminated by an acute apex, and the tooth is either straight, or more commonly bent a little beyond the base, or simply recurved, or with a slight sigmoid inflection. Thus the teeth are adapted for piercing, tearing, and holding, not for dividing or bruising. Certain teeth in some species are traversed by a longitudinal groove, as above noticed, for conveying an acrid saliva into the wounds which they inflict; in others, two or more teeth are longitudinally perforated for transmitting venom. These poison fangs, he remarks, are always confined to the superior maxillaries, as we have already stated, and are generally placed near the anterior extremity of those bones. Professor Owen notices in the first instance the serpents whose teeth are all simple and solid, where the pulp which occupies the basal cavity is calcified. After this the teeth of the poisonous serpents are described, and Professor Owen calls attention to the fact that in certain genera of non-venomous serpents, as in *Dryophis*, *Dipsas*, and *Bucephalus*, in which the superior maxillary teeth increase in size towards the posterior part of the bone, the large terminal teeth of the series are traversed along their anterior and convex side by a longitudinal groove. In the *Bucephalus Capensis* the two or three posterior maxillary teeth present this structure, and are much larger than the anterior teeth or those of the palatine or premandibular series; they add materially therefore, he observes, to the power of retaining the prey, and may conduct into the wounds which they inflict an acrid saliva, but they are not in connection with the duct of an express poison-gland. The long grooved fangs are either firmly fixed to the maxillary bones, or are slightly moveable, according to their period of growth; they are concealed by a sheath of thick and soft gum, and their points are directed backward. The sheath also contains loose recumbent grooved teeth, ready to succeed those in place. In most of the Colubers each maxillary and premandibular bone includes from 20 to 25 teeth: they are less numerous in the genera *Tortrix* and *Homalopsis*, and are reduced to a still smaller number in the poisonous serpents, in the typical genera of which the short maxillary bone supports only a single perforated fang. The transition to the poisonous serpents, which was begun in the *Bucephali* and allied genera with grooved maxillary teeth, is, according to Professor Owen, completed by the poisonous serpents of the genera *Pelamys*, *Hydrophis*, *Elaps*, *Bungarus*, and *Hamadryas*, which latter genus, as its cervical integument can be expanded into a hood, constitutes an immediate link between the *Bungarus* and *Naja*. The structure of the venom-fangs of serpents, and the machinery by which their deadly agency is brought to bear against those who are so unfortunate as to be the objects of their attacks, are so interesting, that we subjoin the following remarks in the author's own words:—"The superior maxillary bone diminishes in length with the decreasing number of teeth which it supports. The transverse or external pterygoid bone elongates in the same ratio, so as to retain its position as an abutment against the shortened maxillary, and the muscles implanted into this external pterygoid style communicate through it to the maxilary bone the hinge-like movements backwards and forwards upon the ginglymoid articulations, connecting that bone with the anterior frontal and palatine bones. As the fully-developed poison-fangs are attached by the same firm basal anchylosis to shallow maxillary sockets, which forms the characteristic mode of attachment of the simple or solid teeth, they necessarily follow all the movements of the superior maxillary bone; when the external pterygoid is retracted, the superior maxillary rotates backwards, and the poison fang is concealed in the lax mucous gum, with its point turned backwards: when the muscles draw forward the external pterygoid, the superior maxillary bone is pushed forwards, and the recumbent fang withdrawn from its concealment and erected. "In this power of changing the direction of a large tooth, so that it may not impede the passage of food through the mouth, we may perceive an analogy between the Viper and the Lophius; but in the fish the movement is confined to the tooth alone, and is dependant on the mere physical property of the elastic medium of attachment. In the serpent the tooth has no independent motion, but rotates with the jaw, whose movements are governed by muscular actions. In the fish the great teeth are erect, except when pressed down by some extraneous force; in the serpent the habitual position of the fang is the recumbent one, and its erection takes place only when the envenomed blow is to be struck. "The peculiar structure of the poison-fang was first described by Fontana, as it exists in the Viper, and subsequently received additional elucidation by Mr. Smith's careful examinations of the fangs of the *Hydrus*, *Naja* and *Crotalus*, and by Mr. Clift's illustrative drawings appended to Mr. Smith's paper. A true idea of the structure of a poison-fang will be formed by supposing the crown of a simple tooth, as that of a *Boa*, to be pressed flat, and its edges to be then bent towards each other, and soldered together so as to form a hollow cylinder open at both ends. The flattening of the fang, and its inflection around the poison-duct, commence

immediately above the base, and the suture of the inflected margins runs along the anterior and convex side of the recurved fang; the poison-canal is thus in front of the pulp-cavity. The basal aperture of the poison-canal is oblique, and its opposite outlet is still more so, presenting the form of a narrow elliptical longitudinal fissure, terminating at a short distance from the apex of the fang. "The character most commonly adduced from the dental system, as distinguishing the venomous from the non-venomous serpents, is, that the former have two, the latter four, rows of teeth in the upper jaw; the two outer or maxillary rows being wanting in the venomous species, and their place being supplied by the single poison-fang. The exceptions to this rule are however too numerous for its value as a distinguishing character in a question of such practical moment as the venomous or non-venomous properties of a serpent. In all the family of Marine Serpents the poison-fang is only the foremost of a row of fixed maxillary teeth. In the *Hydrophis striatus* there are four teeth, and in *Hydrophis schistosa* five teeth, behind the venom fang, of rather smaller size than it; the Two-Coloured Sea-Snake (*Pelamys bicolor*) has also five maxillary teeth in addition to the perforated one. The poison fang in this genus is relatively smaller than in the venomous serpents of the land, but present the same peculiar structure. The poison-gland presents a correspondingly small development; it is pyriform, and its structure, according to Dr. Cantor ('Zool. Trans.,' vol. ii. p. 304), minutely cellular; it is covered by the aponeurotic expansion of the articulo-maxillaries, and transmits a straight duct horizontally to the basal opening of the venom-fang. It is a curious fact that the smaller non-venomous teeth of the poisonous serpents all present a trace of the structures of the functional venom-fang, being more or less deeply grooved along the convex anterior side; and in the *Hydrus* this groove commences by a depression analogous to the oblique basal aperture of the poison-canal in the true fang. "The colubriform poisonous serpents of the land have comparatively short venom fangs, but they are larger than those of the pelagic serpents; and behind the venom-fangs there are likewise some smaller grooved teeth in the maxillary bones; there are three such teeth in the *Bungarus Pama*, and five in the *Bungarus annulatus*. In the *Hamadryas*, or Great Hooded Poisonous Tree-Snake of India, the venom-fang is relatively as large as in typical poisonous serpents, but three or four smaller grooved teeth are implanted behind it on the maxillary bone. "In the most deadly venom-snakes, as the Viper (*Berus*), the Puff-Adder (*Vipera*), the Asps or Hooded Snakes (*Naja*), the Rattle-Snakes (*Crotalus*), and the Cophias and Fer-de-Lance (*Trigonocephalus*,) the poison-fangs acquire their largest size, and are associated only with their successors. These are clustered in greater or less number behind them, presenting the same structure, but of a size proportionate to their degree of development, and further differing in being loosely imbedded in the thick and wide mucous gum, which likewise conceals the fixed and functional fang in its ordinary position of retraction and repose. This fang is more strongly curved backwards than the ordinary teeth, but its acute and slender apex is frequently bent slightly in the contrary direction, as in the Rattle-Snake. The mechanism by which the short maxillary bone and the poison fang are rotated backwards and forwards upon the ginglymoid joint that connects the maxillary with the præfrontal and palatine bones has already been noticed; and as some description of the secreting apparatus to which the peculiar modification of the venom-fang is subservient might here be expected, I have selected for its illustration the accurate figure which Professor Muller has given of the salivary and poison-glands in the *Trigonocephalus lanceolatus*, in his great work on the glandular system. ('De Glandularum Scernentium Structura Penitiori,' fol., tub. vi. fig. 1, p. 55.) "The poison-glands occupy the sides of the posterior half of the head; each consists of a number of elongated narrow lobes, extending from the main duct which runs along the lower border of the gland upwards and slightly backwards. Each lobe gives off lobules throughout its extent, thus presenting a pinnatifid structure; and each lobule is subdivided into smaller secerning cæca, which constitute the ultimate structure of the gland. The whole gland is surrounded by a double aponeurotic capsule, of which the outermost and strongest layer is in connection with the muscles by whose contraction the several cæca and lobes of the gland are compressed and emptied of their secretion. This is then conveyed by the duct to the basal aperture of the poison-canal of the fang. We may suppose, that as the analogous lachrymal and salivary glands in other animals are most active during particular emotions, so the rage which stimulates the venom-snake to use its deadly weapon must be accompanied with an increased secretion and great distension of the poison-glands; and as the action of the compressing muscles is contemporaneous with the blow by which the serpent inflicts its wound, the poison is at the same moment injected with force into the wound from the apical outlet of the perforated fang. "The duct which conveys the poison, although it runs through the centre of a great part of the tooth, is nevertheless, as we have seen, really on the outside of the tooth, the canal in which it is lodged and protected being formed by a longitudinal inflection of the parieties of the pulp-cavity or true internal canal of the tooth. This inflection commences a little beyond the base of the tooth, where its nature is

readily appreciated, as the poison-duct there rests in a slight groove or longitudinal indentation on the convex side of the fang; as it proceeds it sinks deeper into the substance of the tooth, and the sides of the groove meet and seem to coalesce, so that the trace of the inflected fold ceases in some species to be perceptible to the naked eye; and the fang appears, as it is commonly described, to be perforated by the duct of the poison-fang. "From the real nature of the poison-canal, it follows that the transverse section of the tooth varies in form in different parts of the tooth; at the base it is oblong, with a large pulp-cavity of a corresponding form, with an entering notch at the anterior surface; farther on, the transverse section presents the form of a horse-shoe, and the pulp-cavity that of a crescent, the horns of which extend into the sides of the deep cavity of the poison-fang. A little beyond this part the section of the tooth itself is crescentic, with the horns obtuse and in contact, so as to circumscribe the poison-canal; and along the whole of the middle four-sixths of the tooth the section shows the dentine of the fang inclosing the poison-cavity, and having its own centre or pulp-canal, in the form of a crescentic fissure situated close to the concave border of the inflected surface of the tooth. The pulp cavity disappears, and the poison canal again assumes the form of a groove near the apex of the fang, and terminates on the anterior surface in an elongated fissure. "If the end of each inflected fold of cement in the tooth of the *Labyrinthodon* were dilated sufficiently to contain a tube, that tooth might convey the ducts of fifty poison-glands deeply imbedded in its substance, and yet all of them actually on the outside of the tooth itself; it is the existence of a single fold of the same kind, but more simple, inasmuch as it is straight instead of wavy, which forms the complication of the viper's fang subservient to the completion of its peculiar offensive weapon. "The venom-fangs of the Viper, Rattle-Snake, and Fer-de-Lance are coated only with a thin layer of a subtransparent and minutely cellular cement. The disposition of the calcigerous tubes is obedient to the general law of verticality to the external surface of the tooth. Since the inflected surface of the tooth can be exposed to no other pressure than that of the turgescent duct with which it is in contact, the tubes which proceed to that surface, while maintaining their usual relation of the right angle to it, are extremely short, and the layer of dentine separating the poison-tube from the pulp-cavity is proportionally thin. The calcigerous tubes that radiate from the opposite side of the pulp-cavity to the exposed surface of the tooth are disproportionately long. "The pulp-cavity, following the form of the tooth itself, presents in a transverse section of this part the form of a fissure describing four-fifths of a circle; the fissure is widest at the middle and at the two extremities; the exterior calcigerous tubes, in quitting the pulp-cavity, form a graceful curve, the convexity being turned towards the nearest horn of the crescent; at the middle of the pulp-fissure the tubes proceed straight to the opposite surface; and at the two extremities of the crescent the central tubes are nearly straight, while the lateral ones radiate in graceful curves which become bolder as they diverge from the central and straighter tubes. Throughout the greater part of the tooth the calcigerous tubes describe their various inflections in a plane transverse to the axis of the tooth; but towards the apex they begin gradually to rise from that plane; and as the pulp-cavity reassumes, with the tooth itself, the simple conical form beyond the termination of the poison-canal, the calcigerous tubes extend to equal distance from the linear-remnant of the pulp-cavity, which has again passed to the centre of the tooth, and those tubes which are continued from its extremity pass to the apex of the fang in a line parallel with the axis of the tooth. The calcigerous tubes present secondary curvatures of a slightly wavy character, which become more marked and irregular near their termination. In whatever part of the section an entire tube could be clearly traced to its termination, it formed an anastomotic loop at the periphery of the dentine with an adjoining tube. The calcigerous tubes present a diameter of the 118,000th of an inch, and they are separated by interspaces equal to four of their own diameters. Each calcigerous tube gives off many primary branches in its course, but is rarely seen to divide dichotomously until it begins to form its irregular sinuosities near the periphery of the tooth. In the transverse section, the primary branches are sent off from the concave side of the tube, at an acute angle with the trunk; the secondary smaller and more numerous branches proceed from the same side of the main tube or of its primary branches, at a less acute angle, into the clear uniting substance; they are remarkably parallel with each other and straight. In old poison fangs the pulp-cavity or fissure is obliterated by ossification of the remains of the pulp. "The external layer of cement is very thin where it covers the crown of the tooth; it is best seen at the line of union of the coadapted margins of the inflected tooth. At this part the cement is more abundant in the viper's tooth, and its transparency permits a bristle inserted into the poison-canal to be seen through it. The layer which coats the inflected surface of the fang is thinner than the outer one, which, from its transparency, has been regarded as enamel. There is however no trace of true enamel upon the teeth of the poisonous serpents, any more than upon those of the innocuous species. The cells of the cement are more minute and

inconspicuous in the poison-fang than in the simple teeth of the Python and Boa. "The teeth of all Ophidians are developed and completed in the original seat of the tooth-germs in all animals, namely, the mucous membrane or gum covering the alveolar border of the dentigerous bones. This gum presents the same lax tissue and is as abundantly developed as in the Pike, Lophius, and many other fishes, in which it likewise serves as the nidus and locality for the complete development of the teeth. "The primitive dental papilla in the common harmless snake very soon sinks into the substance of the gum and becomes inclosed by a capsule. As soon as the deposition of the calcareous salts commences in the apex of the papilla, the capsule covering that part becomes ossified and adherent to the dentine, and the tooth begins to pierce and emerge from the gum, before its mould, the pulp, is half completed. Fresh layers of cells are successively added to the base of the pulp, and converted by their confluence and calcification into the tubular dentine, until the full size of the tooth is attained, when its situation in the gum is gradually changed, and its base becomes anchylosed to the shallow cavity of the alveolar surface of the bone. "In the posterior part of the large mucous sheath of the poison fang, the successors of this tooth are always to be found in different stages of development; the pulp is at first a simple papilla, and when it has sunk into the gum the succeeding portion presents a depression along its inferior surface, as it lies horizontally, with the apex directed backwards; the capsule adheres to this inflected surface of the pulp. But how the cylindrical cavity of the dilated fold is occupied in the loose growing poison-fang, and by what contrivance it is brought into the same relation with the severed duct of the poison-gland as the displaced fang which it succeeds, is not yet clearly understood." The following list of the distribution of the Asiatic species of *Ophidia* is given by Dr. J. E. Gray in his 'Catalogue of Snakes' in the British Museum. In this list the *Colubridæ* are not included:—

ASIA AND ITS ISLANDS.

Tri esurus viridis
T. albolabris. *China.*
T. carinatus.

C. maculata.—*Eng. Cyc.*

(5881) OPHIOGLOSSACEÆ, *Adders Tongues*, a natural order of Acrogenous Plants, belonging to the alliance Filicales. They have an erect or pendulous stem, with a cavity in the middle instead of pith, and two or three woody bundles placed round it in a ring; the stalks of the leaves and the stem become blended together below; the leaves have netted veins; the spore-cases are collected into a spike formed out of the sides of a contracted leaf, 2-valved, without any trace of an elastic ring; spores resembling fine powder. These plants are a transition from Ferns to *Lycopodiaceæ*. The species are most abundant in the islands of tropical Asia. They occur however in the West Indies and in the tropical parts of Africa, at the Cape, and in Tasmania. They are of little or no known use. The following genera with about 25 species belong to this order:—*Ophioglossum*, *Ophiodema*, *Helminthostachys*, *Botrycyium*.—*Eng. Cyc.*

(5882) OPHIOGLOSSUM (ὀφις, a snake, and γλῶσσα, the tongue), a genus of Plants belonging to the natural order *Ophioglossaceæ*. The thecæ are connate, disposed in a simple distichous spike attached to an undivided frond.—*Eng. Cyc.*

(5883) OPHIORRHIZA MUNGOS Loheh of Avicenna, *Roxb. Fl. Ind.* i. 701.

Wal, eka, weriya, Cing.

A native of Java, Ceylon, and Sumatra; all parts are intensely bitter: it has high reputation as a remedy for snake-bites. Roxburgh altogether discredits its supposed virtues. This plant is often confounded with the Ophioxylon serpentinum, of the family of *Apocyneæ*, (*Chundra*, Bengalee), described by Roxburgh, (Fl. Ind. ii. p. 530, *ed. Carey*) and by Ainslie, vol. ii. 441.—*O'Shaughnessy*, *p.* 400. Dr. Wight, in Icones gives, Ophiorrhiza eriantha, 1067; grandiflora, 1069; Harrisonii, 1162; Roxburghiana, 1068.

(5884) OPHIOXYLON (from ὄφις, a serpent, and ξύλον, wood, because it has a twisted

root and stems), a genus of Plants belonging to the natural order *Apocynaceæ*. It has a 5 cleft permanent calyx, a funnel shaped corolla with a long tube, thickest in the middle, and a five cleft oblique limb. The anthers are subsessile, inserted into the middle of the tube. The ovary is double, each lobe with one ovule, a filiform inclosed style and a capitate stigma. The drupes are baccate, black, about the size of a pea, twin, or solitary by abortion, each containing a 1-seeded wrinkled nut.—*Eng. Cyc.* Wight gives Ophioxylon Belgaumense, 1292; Ceylanicum, 1291; macrocarpum, 1292; Neilgherrense, 1292; serpentinum, 819.

(5885) OPHIOXYLON SERPENTINUM. Scarlet Flowered Ophioxylon, Lin. Various parts of India. See Roxb. Fl. Ind. i. p. 694.

Soovana Amel podie, Mal.	Chandraca, Sans.
Chota Chand, Hind.	Chota Chand, Beng.
Acawerya, Cyng	

Serpentine Snake-Wood, is a native of the East Indies. In rich soil it becomes a climbing plant, but in poor soil it is a small erect shrub. The leaves are in threes or fives; they are short-stalked, oblong, pointed, wavy, and smooth. The peduncules are long, smooth, round, sometimes nearly erect, somtimes drooping. The pedicles and calyxes are of a bright red colour, and the corollas white. In India the root of this plant is employed by the Telinga physicians as a remedy in many diseases. *Eng. Cyc* The stems are woody, erect, climbing, and twining. The root is used as a febrifuge, as an antidote to snake poison, and to *promote delivery* in tedious cases. *Lindley, page* 532., *O'Shaughnessy, page* 447. Soovana Amelpoodie is the name given on the Malabar Coast to this plant, the root of which is supposed to have sovereign virtues in cases of snake bites and scorpion stings: it is prescribed in decoction to the extent of a pint in the twenty-four hours and the powder is applied externally to the injured part. See *Hort. Mal. Part.* 6, *page* 82. This plant is by some believed to be that to which the Mungoose (chneumon) was said to have recourse in his battles with poisonous serpents.—*Ains. Mat. Med. p.* 115.

(5886) OPLISMENUS STAGNINUS. Cultivated in the gardens at Kotah, but the inhabitants do not believe in its reputed virtues.—*Genl. Med. Top. p.* 185.

Enormous islets of living water-grasses (*Oplismenus stagninus*) and other plants, float on the Megny river.—*Hooker, Him. Jour. Vol.* II *page* 338.

(5887) OPIUM.

Opium is the concrete inspissated juice of the white poppy, *Papaver somniferum* and its varieties, obtained by scratching the capsules and collecting the exuding juice. The plant has been long known, and is perhaps one of the earliest described. It is a native of Western Asia and probably also of the South of Europe, but it has been distributed over various countries. In 1826, the imports of opium into the United Kingdom were 79,829 lbs., of which 28,329 lbs. were consumed in England. The imports and consumption in subsequent years are shown by the following figures:—

	Imports. lbs.	Consumption. lbs.
1827	113,149	17,322
1830	209,076	22,668
1833	106,846	35,407
1836	130,794	38,943
1839	196,247	41,632
1842	72,373	47,432
1845	259,644	38,229
1848	200,019	61,055
1849	105,724	44,177
1850	126,318	42,324
1851	118,024	50,682
1852	205,780	62,521

Few who have not looked into the statistics of this trade, are aware of the enormous consumption of opium all over the world, but chiefly in China and India. In 1845, 18,792 chests of opium were sent from Calcutta to China, and nearly the same number of the Malwa opium from Bombay and Damaun. The total production of India exported to China, in 1844, was 21,526 chests from Bengal, and 18,321 from Bombay, in all 39,847 chests. The number of persons in China given to the consumption of opium was estimated, in 1837, at three millions, and the average quantity smoked by each individual is about 17½ grains a day. The consumption of Indian opium (independent of Turkey opium) in China has gradually increased from 3,210 chests in 1817, to 9,969 chests in 1827, and about 40,000 chests in 1837, valued at 25,000,000 dollars. Now it has reached 50,000 to 60,000 chests. Notwithstanding severe penalties, imprisonment, temporary banishment, and even death, the number of those who smoke opium has multiplied exceedingly, and the contraband trade in the drug is carried on to so large an extent, that it is to be feared the practice will become general throughout the empire. According to Mr, E. Thornton's statistics, the production of opium in Bengal has increased cent. per cent. in the last ten years:—

	chests.
1840-41	17,858
1841-42	18,827
1842-43	18,362
1843-44	15,104
1844-45	18,350
1845-46	21,437
1846-47	21,648
1847-48	30,515
1848-49	36,000

The chest is about 140 lbs., so that the production in 1849 was 5,040,000 lbs. According to the statements annexed to the statistical papers relating to India, the income from the opium monopoly is obtained by two principal means, namely, by a system of allowing the cultivation of the poppy by the natives of British India on account of Government, and by the impost of a heavy duty on opium grown and manufactured in foreign states, but brought in transit to a British port for exportation. The former system obtains in Bengal, the latter in Bombay. According to the statements published, Bengal opium yields a profit of 7s. 6d. per lb., whilst the duty derived in the Bombay presidency is only equal to a surplus of 5s 8d. per lb. By these means the total revenue realised by the opium monopoly, in Bengal and Bombay, in the year 1849-50 yielded £3,309,637.

The white variety of the poppy is that which is exclusively brought under cultivation for the production of the drug in India and Egypt. For the successful culture of opium a mild climate, plentiful irrigation, a rich soil, and diligent husbandry are indispensable. One acre of well cultivated ground will yield from 70 lbs. to 100 lbs. of "chick," or inspissated juice, the price of which varies from 6s. to 12s. a pound, so that an acre will yield from £20 to £60 worth of opium at one crop. Three pounds of chick will produce one pound of opium, from the third to a fifth of the weight being lost in evaporation. A chief chemical feature, which distinguishes Bengal opium from that of Turkey and Egypt, is the large proportion which the narcotine in the former bears to the morphia, and this proportion is constant in all seasons. It is a matter of importance to ascertain whether the treatment which the juice receives after its collection can influence in any way the amount of alkaloids, or of the other principles in opium. In Turkey it is the custom to beat up the juice with saliva, in Malva it is immersed as collected in linseed oil, whilst in Bengal it is brought to the required consistence by mere exposure to the air in the shade, though, at the same time, all the watery particles of the juice that will separate are drained off, and used in making *Lewah*, or inferior opium.

The lands selected for poppy cultivation are generally situated in the vicinity of villages where the facilities for manuring and irrigation are great

est. In such situations and when the soil is rich, it is frequently the practice with the cultivators to take a crop of Indian corn, maize, or vegetables off the ground during the rainy season, and after the removal of this in September, to dress and manure the ground for the subsequent poppy sowings. In other situations, however, and when the soil is not rich, the poppy crop is the only one taken off the ground during the year, and from the commencement of the rains in June or July, until October, the ground is dressed and cleaned by successive ploughings and weedings, and manured to the extent which the means of the cultivator will permit. In the final preparation of the land in October and November, the soil, after being well loosened and turned up by the plough, is crushed and broken down by the passage of a heavy log of wood over its surface, and it is in this state ready for sowing. The amount of produce from various lands differs considerably. Under very favorable circumstances of soil and season, as much as twelve or even thirteen seers (26 lbs.) of standard opium may be obtained from each biggah of 27,225 square feet. Under less favorable conditions the turn out may not exceed three or four seers, but the usual amount of produce varies from six to eight seers per biggah. The chemical examination of different soils in connection with their opium-producing powers, presents a field for profitable and interesting inquiry; nor is the least important part of the investigation that which has reference to variations in the proportions of the alkaloids (especially the morphia and narcotine), which occur in opium produced in various localities. That atmospheric causes exert a certain influence in determining these variations is probable; that they influence the amount of produce, and cause alterations in the physical appearance of the drug, are facts well known to every cultivator: thus the effect of dew is to facilitate the flow of the juice from the wounded capsule, rendering it abundant in quantity, but causing it at the same time to be dark and liquid. An easterly wind (which in India is usually concomitant with a damp state of atmosphere), retards the flow of juice, and renders it dark and liquid. A moderate westerly wind, with dew at night, form the atmospheric conditions most favorable for collection, both as regards the quantity and quality of the exudation. If, however, the westerly wind (which is an extremely dry wind) blow violently, the exudation from the capsules is sparing. Whilst the effect of meteorological phenomena in producing the above results are well marked, their action in altering the relative proportions of the chemical constituents of the juice of the poppy plant is more obscure, and it is highly probable that the chemical composition of the soil plays a most important part in this respect. Dr. O'Shaughnessy is

certainly the most accomplished chemist who had ever, in India, turned his attention to the subject, and he has published the results of his analyses of specimens of opium from the different divisions of Behar Agency, which are worthy of much attention. In the opium from eight divisions of the agency, he found the quantity of morphia to range from 1¾ grains to 3½ per cent., and the amount of the narcotine to vary from ¾ grain to 3½ grains per cent, the consistence of the various specimens being between 75 and 79 per cent. In the opium from the Hazareebaugh district (the consistence of the drug being 77), he found 4 ½ per cent. of morphia, and 4 per cent narcotine; whilst from a specimen of Patna-garden opium he extracted no less than 10¾ per cent. of morphia, and 6 per cent. of narcotine, the consistence of the drug being 87. With respect to the last specimen, Dr. O'Shaughnessy mentions that the poppies which produced it were irrigated three times during the season, and that no manure was employed upon the soil. It is much to be regretted that these interesting results were not coupled with an analysis of the soils from which the specimens were produced, for to chemical variations in it must be attributed the widely different results recorded above.

Opium as a medicine has been used from the earliest ages; but when it was first resorted to as a luxury, it is impossible to state, though it is not at all improbable that this was coeval with its employment in medicine, for how often do we find that, from having been first administered as a sedative for pain, it has been continued until it has taken the place of the evil. Such must have happened from the earliest ages, as it happens daily in the present; but as a national vice it was not known until the spread of Mahomedanism, when, by the tenets of that Prophet, wine and fermented liquors being prohibited, it came in their stead along with the bang or hascheesh (made from hemp), coffee, and tobacco. From the Arabs the inhabitants of the Eastern Archipelago most probably imbibed their predilection for opium, although their particular manner of using it has evidently been derived from the Chinese. China, where at present it is so extensively used, cannot be said to have indulged long in the vice. Previous to 1767 the number of chests imported did not exceed 200 yearly; now the average is 50,000 to 60,000. In 1773 the East India Company made their first venture in opium, and in 1796 it was declared a crime to smoke opium. In different countries we find opium consumed in different ways. In England it is either used in a solid state, made into pills, or a tincture in the shape of laudanum. Insidiously it is given to children under a variety of quack forms, such as "Godfrey's cordial," &c. In India the pure opium is either dissolved in water and so used, or rolled into pills. It is there a common Native practice to give it to children when very young, by mothers, who require to work and cannot at the same time nurse their offspring. In China it is either smoked or swallowed in the shape of *Tye*. In Bally it is first adulterated with China paper, and then rolled up with the fibres of a particular kind of plantain. It is then inserted into a hole made at the end of a small bamboo, and smoked. In Java and Sumatra it is often mixed with sugar and the ripe fruit of the plantain. In Turkey it is usually taken in pills, and those who do so, avoid drinking any water after swallowing them, as this is said to produce violent colics; but to make it more palatable, it is sometimes mixed with syrups or thickened juices; in this form, however, it is less intoxicating, and resembles mead. It is then taken with a spoon, or is dried in small cakes, with the words "Ma-sha-Allah," imprinted on them. When the dose of two or three drachms a day no longer produces the beatific intoxication, so eagerly sought by the opiophagi, they mix the opium with other drugs. It then acts as a stimulant. In addition to its being used in the shape of pills, it is frequently mixed with hellebore and hemp, and forms a mixture known by the name of majoon, whose properties are different from that of opium, and may account in a great measure for the want of similitude in the effect of the drug on the Turk and the Chinese. In Singapore and China the refuse of the chandu, the prepared extract of opium, is all used by the lower classes. This extract, when consumed, leaves a refuse, consisting of charcoal, empyreumatic oil, some of the salts of opium, and a part of the chandu not consumed. Now one ounce of chandu gives nearly half an ounce of this refuse, called Tye, or Tinco. This is smoked and swallowed by the poorer classes, who only pay half the price of chandu for it. When smoked it yields a further refuse called sam shing, and this is even used by the still poorer, although it contains a very small quantity of the narcotic principle. Sam shing, however, is never smoked, as it cannot furnish any smoke, but is swallowed, and that not unfrequently mixed with arrack.

Preparation of Opium in India.—Towards the end of March when the plant is nearly ripe the bleeding of the capsules takes place. This operation is performed in the evening, and consists of tracing four parallel lines with a sharp knife or shell, penetrating the epicarp and sarcocarp of the capsule; a milky juice immediately exudes and its flow is promoted by the deposition of dew during the night; each set of incisions yields on an average one grain of opium. This is removed the ensuing morning, and the incisions repeated as long as any milk flows. The whole of the opium collected daily, and which is

necessarily mingled with variable proportions of dew, is mixed together in earthen or wooden vessels. Should the quantity of dew have been excessive, a partial solution of the opium occurs, and an exudation of drops of a black, shining liquid (Pasewa) occurs, on the surface of the opium. This pasewa contains many of the active principles of the drug, and should be mixed with it again to secure the uniform power of the mass. The proportion of pasewa is often much increased by the fraudulent admixture of water by the growers, in hope of having their opium purchased by the gross weight. When brought to the factories the opium is usually of the consistence of 64 to 68, that is, containing that proportion of solid matter per 100. It is then placed in large tanks of brick work, or in wooden vats, with the upper surface exposed to the air. From these reservoirs, portions are daily removed and exposed on wooden trays three inches deep by four feet long and two broad; evaporation takes place under such circumstances with tolerable rapidity, and the opium eventually reaches the consistence of 70—the standard of the factory for the Chinese investment. The degree of inspissation is estimated on the purchase of the drug, as well as during its subsequent evaporation, by drying average portions of 100 grains each, on a metallic table heated to 208° by steam. A sufficient quantity of opium, average quality, is permitted to attain the consistence of 80°, and in that state is issued under the name of "Abkaree" to the licensed dealers of the bazars. Lastly, the finest opium which can be procured is set apart for medical purposes, and allowed to lose by evaporation nearly the entire of its water. The *Chinese investment opium* is of a rich chesnut colour, translucent at the edges of thin masses, tears into portions with ragged margins; its structure is granular, its taste hot and bitter, its smell rich, peculiar, and agreeable; if a small portion be rubbed between the finger and thumb for a few seconds, it draws out into long colourless threads, and from the number, fineness, and tenacity of these threads the Chinese form their first estimate of the value of the drug. The *abkaree*, or Bengal bazar opium is more solid than the Chinese investment drug, of a darker colour, and often of a heavy ascescent smell. For the Chinese investment the opium is made into cakes, each containing 4 lbs., and enveloped in a case made of the petals of the poppy, and agglutinated with a paste made of opium and water, (Lewa). The abkaree opium is also vended in balls weighing 2lbs. covered by strips of a coarse kind of silk cemented by a mucilage of gum. The medicinal opium is solid, brittle in the cold season, of a brown colour, and fine smell. The medicinal drug is packed with great care in 4lb. and 2lb. squares, covered with layers of talc, and further defended by a case of brown wax ½ an inch in thickness. Besides the above, several kinds of opium are to be met with even in Indian commerce—that from Malwah demands most attention.

Malwah opium.—There are many varieties of this opium, some of which the Bengal Committee who investigated the drugs, had oportunities of examining through the kindness of Dr. Morehead of Bombay. The specimens were (average) 1½lb. in weight, hard, brittle, containing from five to ten per cent. of moisture, mixed with fragments of leaves and seeds, and impregnated with oil, apparently used in the collection; the colour was almost a rusty brown, the odour very powerful, and taste intensely bitter and lasting. Besides the opiums above mentioned, it is necessary to notice the chief varieties alluded to in works on European Materia Medica. *M. Berthemot*, in a paper published in the "Journal de Pharmacie," for September 1838, describes three principal kinds, viz.—1st. the opium of Alexandria; 2d. of Constantinople; 3rd. of Smyrna.

Alexandrian opium is in small, very dry, pieces, enveloped in fragments of leaves, of a very deep brown colour, clean and shining fracture, of faintly virose smell.

Constantinople, variety is in two forms, usually in flattened morsels contained in large leaves, sometimes rather soft, occasionally dry and brittle, softening between the fingers, and translucent when pressed into thin layers. The smell is stronger than that of the former kind, and is deemed a sufficient distinguishing sign between both.

Smyrna opium, lastly, is either in flat pieces, or roundish balls; one kind is very dry, wrapped up in large leaves, of shining fracture, reddish brown colour internally, of bitter, acrid, and enduring taste. The second kind is rolled in seeds of the Rumex, is soft, and easily torn, of fawn colour internally, but darkens rapidly on exposure to the air, transparent when drawn out, and often mixed with the seeds which constitute its outer covering. The Smyrna opium is the most valuable of the varieties now described, containing the largest proportion of the narcotic alkali morphia, and in a state which permits this principle to be purified with greatest ease.—*O'Shaughnessy, p.* 172-174.

Preparation in Asia Minor.—Men, women, and children, a few days after the flower falls from the poppies, proceed to the fields, and with a shell scratch the capsules, wait twenty-four hours, and collect the tears, which amount to two or three grains in weight from each capsule. These being collected and mixed with the scrapings of the shells, worked up with saliva and surrounded by dried leaves, it is then sold, but, generally speaking, not without being still more adulterated with cow's dung, sand, gravel, the petals of flowers, &c. Different kinds of opium are known in the markets of Europe and Asia.

The first in point of quality is the *Smyrna*, known in commerce as the *Turkey* or *Levant*. It occurs in irregular, rounded, flattened masses, seldom exceeding two pounds in weight, and surrounded by leaves of a kind of sorrel; the quantity of morphia said to be derived from average specimens is eight per cent.

Second, *Constantinople Opium*, two kinds of which are found in the market, one in very voluminous irregular cakes, which are flattened like the Smyrna; this a good quality. The other kind is in small, flattened, regular cakes, from two to two and a half inches in diameter, and covered with the leaves of the poppy; the quantity of morphia is very uncertain in this description of opium, sometimes mounting as high as 15 per cent., and sometimes descending so low as six, showing the great variety in the quality of the drug.

Third, *Egyptian Opium*, occurs in round flattened cakes, about 3 inches in diameter, and covered externally with the vestiges of some leaf. It is distinguished from the others by its reddish color, resembling "Socotrine Aloes." The quantity of morphia in this is inferior to the preceding. It has one quality which, when adulterated, ought to be known, that is a musty smell. By keeping it does not blacken like the other kinds.

Fourth, *English Opium*, is in flat cakes or balls enveloped in leaves. It resembles fine Egyptian opium more than any other kind. Its color is that of hepatic aloes, and in the quantity of morphia it is inferior to the preceding, but in the strength of the mass it is said by one of its most extensive cultivators to be superior.

Fifth, *French*, and sixth *German Opium*, require no particular remarks.

By a recent notice, the French are cultivating the poppy in Algeria, from which they get opium giving a small per centage of morphia.

Seventh, *Trebizond* or *Persian Opium*, is sometimes met with of a very inferior quality in the form of cylindrical sticks, which by pressure have become angular.

Eighth, *Indian Opium*, divided into four kinds, Cutch, Malwa, Patna and Benares. Of these *Cutch* is but little known or cultivated. It occurs in small cakes covered with leaves, and its color is much inferior to Smyrna. *Malwa* opium is to be met with of two kinds. The inferior is in flattened cakes, without any external covering, dull, opaque, blackish brown externally, internally somewhat darker, and soft. Its color is somewhat like the Smyrna, but less powerful, and with a slight smoky smell. Superior Malwa is in square cakes, about three inches in length and one inch thick. It has the appearance of a well prepared, shining, dry, pharmaceutical extract; its color is blackish brown, its odor less powerful than Smyrna; it is not covered by petals as the following kinds are, but smeared with oil; it is then rubbed with pounded petals. The *Behar*, *Patna*, and *Benares* Opium, being strictly in the hands of Government, no adulteration can take place, without a most extensive system of fraud; but it will not be uninteresting to trace the progress of the opium from the hands of the natives, to the condition in which it is delivered to the public by the Government. From the commencement of the hot season to the middle of the rains the Government is ready to receive opium, which is brought by the natives every morning, in batches, varying in quantities from twenty seers to a maund. The examining officer into each jar thrusts his examining rod, which consists of a slit bamboo, and, by experience, he can so judge of the qualities of the specimens before him, which are sorted into lots of No. 1 to No. 4 quality. Opium of the first quality is of a fine chesnut color, aromatic smell, and dense consistence. It is moderately ductile, and, when the mass is torn, breaks with a deeply notched fracture, with sharp needle-like fibres, translucent and ruby red at the edges. It is readily broken down under water, and the solution at first filters of a sherry color, which darkens as the process proceeds. One hundred grains of this yield an extract to cold distilled water of from 35 to 45, and at the temperature of 212 degs., leaves from 20 to 28 per cent., having a consistency of 70 to 72, the consistence of the factory. The second quality is inferior to the first, and the third quality is possessed of the following properties, black paste, of a very heavy smell, drops from the examining rod, gives off from 40 to 50 per cent. of moisture, and contains a large quantity of "Pasewa;" while the fourth or last number embraces all the kinds which are too bad to be used in the composition of the balls, comprising specimens of all varieties of color and consistence. This number is mixed with water, and only used as a paste to cement the covering of the balls. The three first qualities are emptied from their jars into large tanks, in which they are kept until the supply of the season has been obtained. The opium is then removed and exposed to the air on shallow wooden frames, until it becomes of the consistency of from 69 to 70, when it is given to the cake maker, who guesses to a drachm the exact weight, and envelops the opium in its covering of petals, cemented by a covering of quality number 4. The balls are then weighed and stored, to undergo a thorough ventilation and drying. Formerly the covering of the balls was composed of the leaves of tobacco; but the late Mr. Flemming introduced the practice of using the petals of the poppy, which was such an improvement that the Court of Directors presented him with 50,000 rupees. The balls, forty in number, are packed in a mango wood case, which consists of two stories with twenty pigeon

holes in each, lined with lath and surrounded by the dried leaves of the poppy. Sometimes these balls are so soft as to burst their skins, and much of the liquid opium running out, is lost. In 1823 many of the chests of Patna lost five catties from this cause, and to this day we have the same thing continuing to occur. Patna chests are covered with bullock hides, Benares with mummies. Dr. Impey, who resided in Malwa from 1843 to 1846, published at Bombay, in 1848, a valuable treatise on the cultivation, preparation, and adulteration of Malwa opium. It was some time before he obtained permission to publish the result of the experience he had acquired in Malwa, and as Government inspector of opium at Bombay. It is the most practical treatise Mr. Simmonds had met with, although a very elaborate, useful paper, by Mr. Little, surgeon, of Singapore, appears in the 2nd vol. of the "Journal of the Indian Archipelago," from which I have quoted the preceding remarks. Mr. Little furnishes a complete history of the drug, and the physical and mental effects resulting from its habitual use. There are also some able remarks in Dr. O'Shaughnessy's Bengal Dispensatory:—For the successful cultivation of opium, a mild climate, plentiful irrigation, a rich soil, and diligent husbandry, are indispensable. In reference to the first of these, Malwa is placed most favorably. The country is in general from 1,300 to 2,000 feet above the level of the sea: the mean temperature is moderate, and range of the thermometer small. Opium is always cultivated in ground near a tank or running stream, so as to be insured at all times of an abundant supply of water. The rich black loam, supposed to be produced by the decomposition of trap, and known by the name of cotton soil, is that prepared for opium. Though fertile and rich enough to produce thirty successive crops of wheat without following, it is not sufficiently rich for the growth of the poppy until largely supplied with manure. There is, in fact, no crop known to the agriculturist, unless sugar cane, that requires so much care and labor as the poppy. The ground is first four times ploughed on four successive days, then carefully harrowed; when manure, at the rate of from eight to ten cart loads an acre, is applied to it; this is scarcely half what is allowed a turnip crop at home. The crop is after this watered once every eight or ten days, the total number of waterings never exceeding nine in all. One begah takes two days to soak thoroughly in the cold weather, and four as the hot season approaches. Water applied after the petals drop from the flower, causes the whole to wither and decay. When the plants are six inches high, they are weeded and thinned, leaving about a foot and a-half betwixt each plant; in three months they reach maturity, and are then about four feet in height if well cultivated. The full-grown seed-pod measures three and a-half inches vertically, and two and a-half in horizontal diameter.

Early in February and March the bleeding process commences. Three small lancet-shaped pieces of iron are bound together with cotton, about one-twelfth of an inch of the blade alone protruding, so that no discretion as to the depth of the wound to be inflicted shall be left to the operator; and this is drawn sharply up from the top of the stalk at the base, to the summit of the pod. The sets of the people are so arranged that each plant is bled all over once every three or four days, the bleedings being three or four times repeated on each plant. This operation always begins to be performed about three or four o'clock in the afternoon, the hottest part of the day. The juice appears almost immediately on the wound being inflicted, in the shape of a thick gummy milk, which is thickly covered with a brownish pellicle. The exudation is greatest over night, when the incisions are washed and kept open by the dew. The opium thus derived is scraped off next morning, with a blunt iron tool resembling a cleaver in miniature. Here the work of adulteration begins—the scraper being passed heavily over the seed-pod, so as to carry with it a considerable portion of the beard, or pubescence, which contaminates the drug and increases its apparent quantity. The work of scraping begins at dawn, and must be continued till ten o'clock; during this time a workman will collect seven or eight ounces of what is called "chick." The drug is next thrown into an earthen vessel, and covered over or drowned in linseed oil, at the rate of two parts of oil to one of chick, so as to prevent evaporation. This is the second process of adulteration—the ryot desiring to sell the drug as much drenched with oil as possible, the retailers at the same time refusing to purchase that which is thinner than half dried glue. One acre of well cultivated ground will yield from 70 to 100 pounds of chick. The price of chick varies from three to six rupees a pound so that an acre will yield from 200 to 600 rupees worth of opium at one crop. Three pounds of chick will produce about two pounds of opium, from the third to a fifth of the weight being lost in evaporation. It now passes into the hands of the Bunniah, who prepares it and brings it to market. From twenty-five to fifty pounds having been collected, is tied up in parcels in double bags of sheeting cloth, which are suspended from the ceilings so as to avoid air and light, while the spare linseed oil is allowed to drop through. This operation is completed in a week or ten days, but the bags are allowed to remain for a month or six weeks, during which period the last of the oil that can be separated comes away; the rest probably absorbs oxygen and becomes thicker, as in

paint. This process occupies from April to June or July, when the rain begins. The bags are next taken down and their contents carefully emptied into large vats from ten to fifteen feet in diameter, and six or eight inches thick. Here it is mixed together and worked up with the hands five or six hours, until it has acquired an uniform color and consistence throughout, become tough and capable of being formed into masses. This process is peculiar to Malwa. It is now made up into balls of from eight to ten ounces each, these being thrown, as formed, into a basket full of the chaff of the seed pods. It is next spread out on ground previously covered with leaves and stalks of the poppy; here it remains for a week or so, when it is turned over and left further to consolidate, until hard enough to bear packing. It is ready for weighing in October or November, and is then sent to market. It is next packed in chests of 150 cakes, the total cost of the drug at the place of production being about fourteen rupees per chest, including all expenses. About 20,000 chests are annually sent from Malwa, at a prime cost charge of two lacs and eighty thousand rupees. It may easily be supposed that manipulations so numerous, complex, and tedious, as those described, give the most ample opportunities for the adulteration to which the nature of the drug tempts the fraudulant dealer.

In order to enable the cultivator to carry on his agricultural operations, he receives from time to time certain advances, the amount of which reaches in the aggregate to about one-half of the value of the estimated out-turn of produce. If the land has been under cultivation in previous seasons, its average produce is known; if it be new land, and considered by the Sub-Deputy Agent as eligible, then the cultivator, in addition to the usual advances, receives an advance of so much per biggah to enable him to bestow a certain amount of extra care in tilling and dressing the soil. The first advance is made on the completion of the agreement or bundobust, and this takes place in September and October. The second advance is made on the completion of the sowings in November, and the final or Chook payment is made immediately after the delivery and weighing of the produce. Nothing therefore can be fairer, to the cultivator than this system of advances; he is subject to no sort of exaction, in the shape of interest or commission on the money which he receives, and it puts within his power the certain means of making a fair profit by the excercise of common care and honesty. It is an established rule in the Agency that the cultivator's accounts of one season shall be definitively settled before the commencement of the next, and that no outstanding balances shall remain over. When a cultivator has from fraud neglected to bring produce to cover his advances, the balances due by him are at once recovered, if necessary by legal means; whereas, if he can satisfactorily show that he has become a defaulter from calamity and uncontrollable circumstances, and that the liquidation of his debt is placed entirely beyond his power, his case is then made the subject of report to the Government by the Agent, with the request that the debt may be written off to profit and loss. These provisions are most wise, for outstanding balances may be made the means of oppression, and to their operation, may be traced a considerable amount of litigation and agrarian crime in the indigo districts of lower Bengal. It is clear that when such balances become so large that the cultivator cannot discharge them, he is no longer a free agent, but is perfectly subservient to the will of his creditor, for whom he must cultivate whether he desire it or not. Such burdens may even be handed down from father to son. The fairness of the Agency system, and the justice with which the cultivators are treated are best evidenced by the readiness with which they come forward to cultivate, and also by the comparative rarity of agrarian crime, arising out of matters connected with the poppy cultivation. Opium is grown to some extent in Egypt; 39,875 lbs. were produced in 1831, and sold at two dollars a pound. At the end of October, after the withdrawal of the Nile waters the seed, mixed with a portion of pulverised earth is sown in a strong soil, in furrows; after fifteen days the plant springs up and in two months has the thickness of a Turkish pipe, and a height of four feet; the stalk is covered with long, oval leaves, and the fruit, which is greenish, resembles small orange. Every morning before sunrise, in its progress to maturity, small incisions are made in the sides of the fruit, from which a white liquor distils almost immediately, which is collected in a vessel; it soon becomes black and thickish, and is rolled into balls, which are covered with the washed leaves of the plant; in this state it is sold. The seeds are crushed for lamp oil, and the plant is used for fuel.—*O'Shaughnessy*, 589. Dr. Royle tells us that Opium seems to have been known from early times. Hippocrates is supposed to have employed it, and Diagoras condemned its use in affections of the eyes and in ear-ache. Dioscorides describes it: but opium does not appear to have been much employed until the time of the Arabs, except in the form of the confections called Mithridatica, Theriaca, and Philonium. The Arabic name *afioon*, the Hindu *ephim*, and the name *afooyung*, by which it is known in China, must all have proceeded from the original Greek name, which is itself derived from *οπος*, juice. The Sanscrit *apoynum* seems to have a similar origin. Opium is obtained by a very simple process, consisting merely in making incisions in the evening into the capsules of the Poppy, shortly after the petals fall off, taking care not to penetrate into the interior, when a milky juice exudes, and

either concretes upon the capsule, whence it may be taken off in little tear-like masses, or earlier in the morning in a softer state. Upon this will depend whether the grains run together, or remain separate even when pressed. When thus collected, they require nothing more than being dried in a warm and airy room, when the opium becomes of a brown colour, with a shining fracture, and has a strong and peculiar odour. Some opium which Dr. Royle prepared in this manner in the Saharunpoor Botanic Garden in 1828-29, was pronounced by the Medical Board of Bengal to be like Turkey opium. Most of the opium made in the Himalayan mountains is similarly prepared, and is of very fine quality. Belon and Olivier describe the Opium of Asia Minor as formed by the assemblage of the small tears collected off the capsules. Dioscorides, however, describes the process as consisting in making incisions into the capsules when the dew has evaporated, collecting the juice in a shell, mixing the several portions, and rubbing them up in a mortar. Kæmpfer gives this as the Persian process, and M. Texier describes it as being adopted in Asia Minor; and it is certainly practised with the immense quantities collected in India in the provinces of Behar and Benares, and of which an excellent description has been given by Dr. Butter in the Journal of the Asiatic Society, v. p. 136. When this method is adopted, the mass will appear homogeneous; when it is omitted, it will appear to be composed of agglutinated tears. Both appearances may be observed in the opium of commerce. Dr. Butter describes the quantity of opium from each capsule as varying according to soil, irrigation, and to the quantity of dew which falls, but averaging about 1 gr. from each quadruple incision. The tears are of a reddish-white colour externally but semi-fluid in the interior, and of a reddish-white colour. The juice is apt to be mixed with dew, and fraudulently with a little water, and will separate into a fluid portion (*passeera*) and into one which is more consistent, the former containing much the largest portion of the Bimeconate of Morphia. The whole of the day's collection is rubbed together in a mortar, so as to break down the grains, and reduce the whole to a homogeneous semi-fluid mass, which should be dried as quickly as possible in the shade, when it is called *pucka* or matured, being called *raw* in its former state. All samples of Opium brought for sale are submitted to a steam drying process, by which the quantity of fluid in each is easily ascertained. The Opium for the China investment contains about 30 per cent. of moisture: that for medical use in India is made quite dry. The Opiums known in European commerce have been described under the following heads by Prof. Guilbourt. That collected in Asia Minor, chiefly in Anatolia, is generally all included under the head of Turkey Opium, and most of it is exported from Smyrna; some of it, however, is taken to Constantinople, whence it is re-exported to other parts of Europe. Some Egyptian is imported into this country. The Persian is only known. The Indian kinds are exported to China.

Smyrna Opium, called also Levant Opium, is generally in flattened masses, and, in consequence of its original softness, without any definite regular form; weighing from a half to two pounds and covered with the capsules of a species of Rumex. It is at first soft, of a distinct brown colour, becoming blackish and hard when dried, losing weight from evaporation of water, having the strong and peculiar odour of Opium. "When examined with a magnifier, it is seen to be composed of yellowish agglutinated tears." This is the purest kind of Opium, yielding about 8 per cent. of Morphia and 4 per cent. of Narcotine, and, on an average, about 12 per cent. of Hydrochlorate of Morphia. An inferior kind is, however, also imported from Smyrna, which is more apt to be adulterated, is harder, of a darker colour, appears homogeneous, and may be seen covered either with Rumex capsules, or with the leaves of the Poppy. The Smyrna Opium is produced at several places, at from 10 to 50 days' distance in the interior; but that grown at Caisar, about 60 miles from Smyrna, is the most esteemed for its cleanness and good quality. Mr. Hamilton states that much is produced at Bogaditza: it is made into lumps about four or five inches in diameter, round which leaves are wrapped.

Constantinople Opium, M. Guibourt conceives, may be collected in the northern parts of Anatolia. One kind is in small lenticular pieces about two inches in diameter, weighing from four to eight ounces, and always covered with a Poppy-leaf, of the midrib of which the mark may be seen on the middle of the pieces of Opium. Another variety is in large irregular cakes. Both are more mucilaginous than the Smyrna kind, and, though of good quality, the Constantinople is less uniform in the quantity of Morphia it contains, some yielding less, and others as much as, the best kinds of Opium.

Egyptian Opium is in flattened roundish cakes about three inches in diameter and covered with the remains of some leaf which M. Guibourt was unable to distinguish. It looks well externally, is homogeneous, has something of a reddish hue, not blackening by keeping, but softening on exposure to the air, and has somewhat of a musty smell. It is generally inferior, and Mr. Guibourt obtained only ¼ of the Morphia yielded by Smyrna Opium.

Persian Opium, which Dr. Pereira calls Trebizond Opium, from his specimens having been obtained from thence. The specimens in the King's College Museum were sent by Mr. Mor-

son, to whom M. Guibourt was also indebted. This kind is of a black colour, apparently homogeneous in texture, and in sticks some inches in length, each wrapped up in a separate piece of paper, and tied with a piece of cotton. Some Opium has been collected in Algiers. A new variety imported from Turkey has been described by Mr. Morson (P. J. iv. 503). It resembled the Constantinople, but was soft and light-coloured; contained much wax, caoutchouc, and about 6½ per cent. of Morphia. Besides these, some Opium is occasionally met with of European manufacture; and it might easily be produced in England if the summer was more regular. In the south of Europe the summer is probably too hot and dry. In India it can only be cultivated in the cold weather. Some good English Opium has been produced, but it is irregular in strength. The quantity of Morphia said to have been obtained from some specimens of French and of German Opium is enormous,—being from 16 to 20 per cent.

Indian Opium, not being known in European commerce, requires a very short notice. The *Saharunpoor Garden Opium*, sent home in 1844, is of a brown colour, shining fracture, with the strong and peculiar smell of opium, and yielded the late Professor Daniell, in one of the last analyses he made previous to his sudden and lamented death, 8 per cent. of Morphia. [Some specimens of this opium, prepared when Dr. Royle was superintendant of the Saharunpore Botanic Garden, sent to the Medical Board of Bengal in 1829, were pronounced to be "very fine specimens, and to resemble Captain Jeremie's in almost every particular," and Captain Jeremie's they "considered equal, if not superior, to the finest Turkey opium that comes into the market at home."

Himalayan Opium possesses similar sensible properties and though liable to be adulterated, is when pure, of very fine quality.

Malwa Opium is in flat circular cakes, average weight 1½ lb., of a rusty-brown colour, strong odour, and bitter permanent taste, varying much in quality. Some Malwa Opium lately analysed yielded only 2 per cent. of Morphia, was oily and mucilaginous, and appeared to have been obtained by expression of the capsules. Dr. Smyttan, late Opium Inspector at Bombay, obtained from 3 to 5 per cent. of Morphia from some varieties, and from 7¼ to 8 per cent. from finer kinds. Some *Kandeish Opium* yielded to Mr. E. Solly 72 per cent. of soluble matter, and about 7 per cent. of Morphia. The E. I. Company's Opium, which is that known under the name of Bengal Opium, and which is chiefly produced in the provinces of Behar and Benares, with some in that of Cawnpore, is also of different qualities: that intended for medicinal use in the hospitals in India is of very fine quality, of a brown colour, and fine smell, packed with great care in 4 lb. and 2 lb. squares covered with layers of talc, and further defended by a case of brown wax half an inch in thickness. This Dr. Jackson, lately Opium Inspector at Calcutta, informed Dr. Royle is the *Patna Garden Opium*, cultivated, prepared, and selected exclusively for the Dispensary, and that it yields about 7 to 8 per cent. and sometimes more (10½), of Morphia. It is of this kind that Dr. Christison says, "I have examined specimens little inferior to average Turkey Opium in the quantity of Morphia they contained."

Chinese Investment Opium, which is highly esteemed by the Chinese, is made into cakes or balls, each containing about 4 lbs. and covered with a thick layer of poppy petals, made to adhere to the opium and to each other by means of a mixture of inferior kinds of Opium and water. It is of a dark brown colour, of the consistence of an extract when first cut into, containing 70 per cent. of solid matter, and about 2½ per cent. of Morphia.—*Royle*. The E. I. Company grant licences for the cultivation of the poppy, and contract for all the produce at certain rates, varying with the quality. No opium can be grown without this licence, and an advance equal to about two-thirds of the value of the produce is made to the grower. This produce is made over to district collectors, who approximately fix the worth of the contents of each jar, and forward it to Patna, where rewards are given for the best samples, and the worst are condemned without payment; but all is turned to some account in the reduction of the drug to a state fit for market. The poppy, and the capsules are sliced in February and March with a little instrument like a saw, made of three iron plates with jagged edges, tied together. The cultivation is very carefully conducted, nor are there any very apparent means of improving this branch of commerce and revenue. During the N. W., or dry winds, the best opium is procured, the worst during moist, or E. and N. E., when the drug imbibes moisture, and a watery bad solution of opium collects in cavities of its substance, and is called Passewa, according to the absence of which the opium is generally prized.—*Hooker Him. Jour. Vol.* I *p.* 83. At the end of March, he continues, the opium jars arrive at the stores by water and by land, and continue accumulating for some weeks. Every Jar is labelled and stowed in a proper place, separately tested with extreme accuracy, and valued. When the whole quantity has been received, the contents of all the jars are thrown into great vats, occupying a very large building whence the mass is distributed, to be made up into balls for the markets. This operation is carried on in a long paved room, where every man is ticketed, and many overseers are stationed to see that the work is properly conducted. Each workman sits on a stool, with a double stage and a tray before him. On the top stage is a tin basin

containing opium sufficient for three balls; in the lower another basin holding water: in the tray stands a brass hemispherical cup, in which the ball is worked. To the man's right hand is another tray, with two compartments, one containing thin pancakes of poppy petals pressed together, the other a cupful of sticky opium-water, made from refuse opium. The man takes the brass cup, and places a pancake at the bottom, smears it with opium-water, and with many plies of the pancakes makes a coat for the opium. Of this he takes about one-third of the mass before him, puts it inside the petals, and agglutinates many other coats over it: the balls are then again weighed, and reduced or increased to a certain weight if necessary. At the day's end, each man takes his work to a rack with numbered compartments, and deposits it in that which answers to his own number, thence the balls (each being put in a clay cup) are carried to an enormous drying-room, where they are exposed in tiers, and constantly examined and turned, to prevent their being attacked by weevils, which are very prevalent during moist winds, little boys creeping along the racks all day long for this purpose. When dry, the balls are packed in two layers of six each in chests, with the stalks, dried leaves, and capsules of the plant, and sent down to Calcutta. A little opium is prepared of very fine quality for the Government Hospitals, and some for general sale in India; but the proportion is trifling, and such is made up into square cakes. A good workmen will prepare from thirty to fifty balls a day, the total produce being 10,000 to 12,000 a day; during one working season 1,353,000 balls are manufactured for the Chinese market alone.—*Hooker Him. Jour. Vol.* I. *p.* 83 & 84. The poppy-petal *pancakes*, each about a foot radius, are made in the fields by women, by the simple operation of pressing fresh petals together. They are brought in large baskets, and purchased at the commencement of the season. The liquor with which the pancakes are agglutinated together by the ball-maker, and worked into the ball, is merely inspissated opium water, the opium for which is derived from the condemned opium, (Passewa,) the washing of the utensils, and of the workmen, every one of whom is nightly laved before he leaves the establishment, and the water is inspissated. Thus not a particle of opium is lost. To encourage the farmers, the refuse stalks, leaves, and heads are bought up, to pack the balls with; but this is far from an economical plan, for it is difficult to keep the refuse from damp and insects.—*Hooker Him. Jour: Vol.* I. *p.* 85. A powerful smell of opium pervaded these vast buildings, which Dr. Corbett assured Dr. Hooker did not affect himself or the assistants. The men work ten hours a day, becoming sleepy in the afternoon; but this is only natural in the hot season: they are rather liable to eruptive diseases possibly engendered by the nature of their occupation.—*Hooker Him. Jour. Vol.* I. *p.* 85. Even the best East Indian opium is inferior to the Turkish, and owing to peculiarities of climate, will probably always be so. It never yields more than five per cent of morphia, whence its inferiority, but is as good in other respects, and even richer in narcotine.—*Hooker Him. Jour. Vol.* I. *page* 85.

Cultivation.—The mode of raising the poppy in the Patna district in India, is thus described. "The ryot or cultivator having selected a piece of ground, always preferring (*cæteris paribus*) that which is nearest his house fences it in. He then, by repeated ploughings, makes it completely fine and removes all the weeds and grass. Next, he divides the field into two or more beds by small dikes of mould, running lengthwise and crosswise according to the slope and nature of the ground, and again into smaller squares by other dikes leading from the principal ones. A tank is dug about ten feet deep at one end of the field, from which by a leathern bucket, water is raised into one of the principal dikes and carried to every part as required; this irrigation is necessary because the cultivation is carried on in the dry weather. The seed is sown in November, and the juice collected in February and March, during a period, usually, of about six weeks; weeding and watering commence as soon as the plants spring up, and are continued till the poppies come to maturity. Cuts are then made in the rind of the seed vessel, with a small shell; from them the juice exudes during the night and is scraped off in the morning; when the heads are exhausted, they become whitish.—*Williams' Middle Kingdom, Vol.* II. *page* 383. This writer seems to exaggerate matters. In his bias he says: the cultivator is assisted by his family and must deliver a certain quantity at such a price to the collector, the amount being fixed by a survey of the field when in bloom; he receives about 165 dollars for a seer (1 lb. 13 oz.) of the poppy juice, which must be of a certain consistence. The ryot has, in most cases, already received the advance money for the opium, and if he sell it to any other than the collector, or if he fail to deliver the estimated quantity, and there is reason for supposing he has embezzled it, he is liable to punishment. In all the territories belonging to the company, the cultivation of the poppy, the preparation of the drug, and the traffic in it until it is sold at auction for exportation, are under a strict monopoly. Should an individual undertake the cultivation without having entered into engagements with the government to deliver the produce at the fixed rate, his property would be immediately attached, and be compelled either to destroy the poppies, or give

security for the faithful delivery of the product. The cultivation of the plant is compulsory, for if the ryot refuse the advance for the year's crop the simple plan of throwing the rupees into his house is adopted; should he attempt to abscond, the agents seize him, tie the advance up in his clothes, and push him into his house. There being then no remedy he applies himself as he may to the fulfilment of his contract. Vast tracts of the very best land in Benares, Bahar, and elsewhere in the northern and central parts of India, are now covered with poppies; and other plants used for food or clothing, grown from time immemorial, have nearly been driven out. In Turkey, Persia, India and China, many myriads of acres and millions of people are employed in the cultivation of poppies. [Note Chinese Repository. Vol. V., page 472.] *Williams' Middle kingdom, Vol.* II. *p.* 383. There are four sorts of opium brought to China: Turkey, which sells cheapest in China, and is brought chiefly from Smyrna; Patna and Benares, which are grown in the Company's territories, and sold at Calcutta; and Malwa, which is cultivated out of their jurisdiction, but pays them a revenue of about 200 rupees each chest for its transit to Bombay where it is shipped. The Portuguese also export a small quantity from their settlement in Damaun. The drug is rolled in balls, and then packed in strong boxes weighing from 116 lbs. for Patna to 134 lbs. or 140 lbs. for Malwa. The Malwa opium is grown and prepared entirely by natives, and is often so extensively adulterated as to be worthless. There are between 400 and 500 cakes in a chest of Malwa, and the cultivator there receives double the wages of the ryot in Bengal. —*Williams' Middle Kingdom, Vol.* II. *p.* 385. The chests of Patna and Benares are made of mango wood, and consists of two stories or parts, in each of which there are twenty partitions; the forty balls to fill these partitions are carefully rolled in dried poppy leaves. The chest is covered with hides or gunny bags, and the seams closed so as to render it as impervious to the air as possible, but considerable allowance is made for dry gage. After the drug is sold at Calcutta, it is shipped in small fasts ailing-vessels for China, more than half of the export from that and other parts in India being sent off in these clippers.—*Williams' Middle Kingdom, Vol.* II. *p.* 385.

Effects of Opium-smoking.—The vice of opium-smoking is now so prevalent in Calcutta, not only among the Chinese, but the degraded, and depraved of every sect and nation, that Dr. O'Shaughnessy had many opportunities of witnessing the results to which it leads. Stupor, reverie, and voluptuous listlessness are the immediate effects produced. In this state the individual can be at once and easily aroused to exertion or business. No sickness, constipation, or any other functional disturbance supervenes on each indulgence; gradually, however, the appetite diminishes, the bowels become irregular, emaciation takes place, sexual tendencies are destroyed, and premature old age speedily comes on. This he admits is an extreme case; when the habit is but moderately followed it appears to occasion no greater evil than the proportionate indulgence in wine or other spirituous liquors.—*O'Shaughnessy, page* 180. Opium, is at present, largely consumed in the Malayan islands, in China, in the Indo-Chinese countries, and in a few parts of Hindustan, much in the same way in which wine, ardent spirits, malt liquor, and cider, are consumed in Europe. Its deleterious character has been much insisted on, but, generally, by parties who have had no experience of its effects. Like any other narcotic or stimulant, the habitual use of it is amenable to abuse, and as being more seductive than other stimulants, perhaps more so; but this is certainly the utmost that can be safely charged to it. Thousands consume it without any pernicious result, as thousands do wine and spirits, without any evil consequence. I know of no person of long experience and competent judgment who has not come to this common-sense conclusion. Dr. Oxley, a physician and naturalist of eminence, and who has had a longer experience than any other man of Singapore, where there is the highest rate of consumption of the drug, gives the following opinion: "The inordinate use, or rather abuse, of the drug most decidedly does bring on early decrepitude, loss of appetite, and a morbid state of all the secretions; but I have seen a man who had used the drug for fifty years in moderation, without any evil effects; and one man I recollected in Malacca who had so used it, was upwards of eighty. Several in the habit of smoking it have assured me that, in moderation, it neither impaired the functions nor shortened life; at the same time fully admitting the deleterious effects of too much." There is not a word of this that would not be equally true of the use and abuse of ardent spirit, wine, and, perhaps even of Tobacco. The historian of Sumatra, whose experience and good sense cannot be questioned, came early to the very same conclusion. The superior curative virtues of opium over any other stimulant are undeniable, and the question of its superiority over ardent spirits, appears to me to have been for ever set at rest by the high authority of Sir Benjamin Brodie. "The effect of opium, when taken into the stomach," says this distinguished philosopher, "is not to stimulate but to soothe the nervous system. It may be otherwise in some instances, but these are rare exceptions to the general rule. The opium-eater is, in a passive state, satisfied with his own dreamy condition while under the influence of the drug.

He is useless but not mischievous. It is quite otherwise with alcoholic liquors.—*Psychological Inquiries, p*: 248. *Crawfurd Dict. page* 313. It may be worth while to show what is really the relative consumption in those countries in which its use is alleged to be most pernicious. In the British settlement of Singapore owing to the high rate of wages, and the prevalence of a Chinese population, the consumption is at the rate of about 330 grains, or adult doses, a year, for each person. In Java, where the Chinese do not compose above one in a hundred of the population, and where wages are comparatively low, it does not exceed 40 grains. Even in China itself where the consumption is supposed to be so large, it is no more than 140 grains chiefly owing to the poverty of the people, to whom it is for the most part inaccessible.—*Crawfurd Dictionary, page* 313. Opium is eaten to a very considerable extent by the Burmese, and the drug is easily procured.—*Mason*. That raised in Bahar (called Patna in commerce) and Benares is superior to the Malwa, and both are preferred by the Chinese to the Turkey opium. Good opium is moderately firm in texture, capable of receiving an impression from the finger; of a dark yellow color when held in the light, but nearly black in the mass, with a strong smell, and free from grittiness. That produced in different countries, however, varies considerably and experience alone can determine the best article. The value increases for a short time by age; but this soon ceases to be the case, and Turkey opium in particular deteriorates unless carefully preserved from the air. Opium is adulterated with leaves, dirt, and other substances; if very soft it is not usually good. The great consumption of this drug among the Chinese has made the opium trade a very important branch of commerce. About fourteen millions of dollars worth have been annually sold to them for many years past, and the demand is constant. The trade is now carried on by means of ships stationed at different points on the coast, to which the drug is carried in small vessels; or it is sold all along the coast in schooners from Haenan to Shanghae, especially at points opposite large towns. No efforts have been made by the Chinese authorities to suppress the traffic that deserve to be mentioned, since those of commissioner Lin in 1839, and it is now everywhere publicly smoked. It is probable that before long the progress of events will compel the Chinese to legalize the trade. The opium brought from India sells from $ 550 to $ 700 a chest, and the Turkey from $ 370 to $ 500 a pecul. The price of the commodity fluctuates, however, according to the extent of importation, and other causes. For minute information respecting the progress and effects of this traffic, see the Chinese Repository, *passim*. —*Morrison*. The extent to which the poppy is cultivated in China bears about as great a disproportion to the consumption of opium, as the growth of tea abroad does to its use; the provinces of Yunnan and Kwangsi are said to produce the greater part of the native article.—*Williams' Middle Kingdom, p*. 286.

Opium shipped to China from East India for following years is:—

Opium Adulterations.—Good Opium, when it has been sometime made, is of a dark brown or blackish colour externally, and of a reddish-brown internally, either homogeneous in texture, or formed of agglutinated tears. Sp: Gr: about 3·36. The taste is strongly and permanently bitter, with some degree of acridity, and a little aroma. The odour is both powerful and peculiar. It is hard, and even becomes brittle, and breaks with a compact shining fracture, and produces a yellowish-brown powder. Some kinds, however, are soft internally, and others never become entirely dry. The London College, to preserve uniformity of strength, directs dried Opium only to be used for the several pharmaceutical preparations. Opium is softened by the application of heat, and burns at a higher temperature. The effects of the ordinary reagents are, that water, either temperate or warmed, dissolves about two-thirds

of good opium, and forms a solution of most of its active principles, and is of a bitter taste and of a reddish-brown colour. Rectified Spirit takes up four fifths of the whole mass, including all the active properties of Opium. Ether dissolves much of what is left undissolved by water. Diluted acids take up all its active principles. The alkalis precipitate them from their solutions, but redissolve them when added in excess. They are also precipitated by baryta, lime, and magnesia, and their salts, also by the soluble salts of lead and of other metals, as well as by solutions of tannin and astringent vegetable substance. As some of these are apt to be prescribed with opium, it is essential to attend to the form of exhibition, for the precipitate may contain all the active principles, and the solution be inert; or it may be made active again by using an excess of ammonia or potash; or the active principle may be taken up by the acid of some of the salts used. But these various effects of reagents can be duly appreciated only when the composition of Opium is understood. Several analys is were made of Opium before any just ideas were obtained respecting its constitution. Derosne in 1803 first obtained a saline body. Serturner and Seguin, the first a Hanoverian, and the second a French apothecary, both discovered in 1804 another crystallizable substance, upon which subsequent experience has proved the narcotic power of opium to depend. In a second memoir of Serturner published in 1817, he announced his discovery of the existence of *morphia* combined with *meconic acid*. This was confirmed by Robiquet. Since then, Geiger, Beltz, Pelletier, Couerbe, Schmidtz, and Mulder, have successively analysed and shown Opium to consist of a variety of principles. Of these, three are alkaline, *Morphia*, *Codeia*, and *Paramorphia*. A fourth, *Narcotin*, though neutral to colours, forms salts with acids: of this a great portion is in a free state, and may at once be separated from Opium by ether; the remainder, as well as the whole of the *Morphia* and *Codeia*, are in combination with the *Meconic* Acid and some *Sulphuric acid* found in Opium. Other bodies are also acid, as the *brown acid extractive*, the *resin*, and *oily matter*. Some are neutral, as *Narcein* and *Meconin*. Narcotin is sometimes enumerated among the neutral principles, and Thebaina, called also Paramorphia, though alkaline, does not combine with acids. Besides these, there is a trace of Volative Oil (the odorous principle ?), Gum, Bessorine, Albumen, Caoutchouc, Lignin, and Salts of inorganic bases. If adultered with

a. Water.—Heat 100 grs on a water bath for half an hour, the loss is water.

„ *b*. Starch, pease-meal, flour—boil 20 grs. with water, strain, allow to cool and tincture of iodine which gives a blue precipitate with these impurities.

„ *c*. Resins, dammar and clay,—subside as a harsh mass during the trituration of 100 grains in distilled water.

„ *d*. Catechu, Gab.—To solution "a" add a solution of isinglass, there is a copious precipitate.

„ *e*. Mucilaginous extracts of bel (fruit of Aegle marmelos) and mekanna, seeds of Euryale ferox—add alcohol to solution "a" previously concentrated to ¼th. A copious precipitate of gummy matter ensues, quite soluble in hot water.

„ *f*. The presence of datura, tobacco and bang can only be detected by the smell of the drug, which resembles that of a bad hookah.—*Ben. Ph.* 2. 8.

Dr. Royle says, Opium is of different degrees of value, according to its sensible properties, and the quantity of Morphia it contains; but it is subject to adulterations. First it may be mixed up with too much water, either intentionally, or in consequence of the dew having been very heavy. The quantity may be ascertained by the loss on evaporation. The most injurious fraud is that of washing out the soluble and most valuable parts of Opium, and bringing the residual mass for sale. In this case Butler states the Opium loses its translucency and redness of colour, also its adhesiveness. Sand, clayey mud, sugar, molasses, cowdung, Datura-leaves, the glutinous juice of Ægle Marmelos, and even pounded poppy-seeds, are employed to adulterate Opium. Malwa Opium often contains oil and other matters obtained by the expression of the poppy-heads. Some Opiums from which Morphia has been extracted have been occasionally met with in European commerce. To be enabled to judge of good Opium, one must be well acquainted with the different varieties of Opium, their respective colours, tastes, and textures, as well as the natural degree of moisture, and see that no mechanical admixtures are apparent, nor left on a filter. Several methods have been proposed for ascertaining the quantity of Morphia in Opium, but none of them are very satisfactory. In the E. P. it is proposed to ascertain it by the weight of the precipitate caused in an infusion of Opium by Carbonate of Soda. "A solution of 100 grs. macerated 24 hours in Aq. f ℥ ij. filtered, and strongly squeezed in a cloth, if precipitated by a cold solution of Carbonate of Soda ℥ fs. in two waters, and heated till the precipitate shrinks and fuses, will yield a solid mass on cooling, which weighs, when dry, at least 11 grains, and if pulverized, dissolves entirely in solution of Oxalic acid." Dr. Pereira

has not found this satisfactory, but considers the process of Thibaumary as the best, in which Ammonia is employed to precipitate the Morphia in infusion of Opium. (v. Mat. Med. p. 1742.) Dr. Christison considers Dr. Gregory's method of obtaining Muriate of Morphia as the only one; but it requires about a pound of Opium to be operated on which, if good, should not yield less than ten per cent. of a snow-white salt.

Action. Uses. Opium, applied *externally*, is at first stimulant, producing pain, as on the eye, and then sedative. When taken *internally*, in small doses, excitement is first produced, as apparent in the increased frequency of the pulse, and heat of the skin. This is soon followed by diminished sensibility, calmness, and sleep, with abatement of pain, suspension of mucous secretion, with the exception of that of the skin. But if the tendency to sleep be resisted, Opium, in moderate doses, and in those habituated to its use, in excessive doses, will produce intellectual excitement accompanied by bodily activity, soon to be followed by general debility, as is exemplified in Opium-eaters. In large doses, it is a narcotic poison. It is frequently employed as an anodyne and hyponotic, as a sedative, and to restrain inordinate discharges, as in diarrhœa and cholera, also as a diaphoretic, often as an antispasmodic, and even as a febrifuge. In Delirium Tremens it is beneficially given in large doses, and, combined with Calomel and sometimes with the addition of Ipecacuanha, even in inflammatory affections; though in general it is contraindicated when there is inflammation or much fever. It is no doubt the most important of all therapeutical agents, and that which is perhaps the most frequently employed.—*Royle.*

(5888) OPOBALSAM, Balm of Gilead, Judiacum de Mecca.

Akooyeela-semoon-i-roomie, Arab.	Balsamier de la Meque, Fr.
Balessan, Egypt.	Opobalsamo, It.
	Roghun-i-Bulsan, Pers.

A liquid gum-resin, obtained from the *Amyris Gileadensis*, a tree found in Arabia, Abyssinia, and Syria. It is first turbid and white; of a pungent smell resembling turpentine, but sweeter; and of a bitter, acrid, astringent taste. When old it becomes thin, limpid, of a greenish hue, then of a golden yellow, and at length of the colour of honey. It is chiefly used as a cosmetic by the Turkish ladies.

(5889) OPOPONAX, a genus of Plants belonging to the natural order *Umbelliferæ*; it has an obsolete calyx, roundish entire petals rolled inwards, with a rather acute lobe; compressed fruit with a dilated convex border, bipinnate leaves with unequally cordate segments, crenated and obtuse. The umbels are compound; the involucre both universal and partial, and the flowers yellow.

(5890) OPOPONAX CHIRONIUM. *Syn.* Pastinaca Opoponax. Ferula op: παναχες ηραχλειον *Dioscor.*

(5891) OPOPONAX CHIRONUM, is native of the south of Europe and Asia Minor, on dry hills, margins of fields, and thickets. It is a plant 6 or 7 feet high, of a dull-yellowish colour, and resembling a parsnip. The stem is strongly furrowed; the leaves from 1 to 2 feet long, or more, flat, bipinnate, with ovate cordate leaflets, which are usually oblique at the base, often confluent, and surrounded by a cartilaginous, crenated border. The calyx is inconspicuous, the styles rather short and stout. Although this plant is a native of the south of Europe, the resinous gum which exudes from the stalk or root when wounded is brought from the Levant and East Indies in roundish drops of a reddish-yellow colour, with specks of white. It is supposed to be an emmenagogue, but it is seldom used; it is similar in its effects to assafœtida. This is a plant of easy culture, and may be propagated either by seeds or dividing at the root.—*Eng. Cyc.*

(5892) OPOPONAX.

Jawasheer, Arab.	Opopo-nace, It.
Opopanax, Fr.	Gawshier, Pers.
Panax gummi, Ger.	Opoponaca, Sp.
Jawasheer, Guz. Hind.	

Off. Prod. Opoponax, gum resin obtained from the stalks of a tall plant (*Opoponax chironium*). According to Pelletier's analysis 100 parts contain—resin 42, gum 33, starch 4, extractive and malic acid 4, volatile oil 5, with traces of caoutchouc and wax, and 9 of woody fibre. The sp. gr. 1622; with water it forms a milky fluid. Opoponax is derived from ὀπος juice, παν all, and ἀχος a remedy, meaning that it is a remedy for all diseases! In action it resembles asafœtida, but is much feebler. The plant occurs in dry fields in the south of Europe and Asia Minor. A milky juice exudes from the root when wounded, and hardens into a fœtid gum resin, in most of its properties closely resembling asafœtida. The resin is found in all the Bazars of Bengal, and is even exported from this country to Europe.—*O'Shaughnessy, page* 361.

(5893) OPOSSUM. [Didelphina; Marsupiata.]

(5894) OPUNTIA, a genus of Plants belonging to the natural order *Cactaceæ*. In the gardens the species are called Indian Figs, and are remarkable for their stems consisting of flat joints, broader at the upper than the lower end, but which eventually lose that appearance, becoming both cylindrical and continuous. On one of them, *O. cochenillifera*, the cochineal insect is fed, and others yield a pleasant sub-acid fruit, which is eaten in hot countries. The lavas of Ætna are in some places covered with the spiny bushes of *O. vulgaris*, whose large purple juicy fruits are carried for sale to the neighbouring

markets. It is however only a naturalised plant, its native country being South America within the tropics.—*Eng. Cyc.*

(5894) OPUNTIA TUNA, has been figured in Dillenius's 'Hortus Elthamensis,' tab. 389, and is the original of what Linnæus called *Cactus Tuna*; it has been since called *Cactus Bonplandii* by Mr. Kunth. It differs from the two following in the long whitish spines that arm it, in its very broad oval joints, its fully-expanded flower, which resembles that of *O. Hernandezii*, except that it is larger. This is the sort which in the Jardin-des-Plantes at Paris nourishes the wild cochineal: it was brought from Peru by Dombey, and according to Humboldt is in much esteem in that country as the food of a valuable sort of cochineal.—*Eng. Cyc.*

(5895) ORACHE, or MOUNTAIN SPINAGE. Of these there are several varieties, commonly known as red and green sag—the leaves are slightly acid; both sorts are boiled as spinage, but the red is most esteemed. Propagated by seed—no particular soil required.—*Riddell.*

(5896) ORANGE, AURANTIUM, Lin. Citrus Aurantium, *Risso*, the common or Sweet Orange.

Panneh dodang, CYNG.	Laranjas, PORT.
Orangen, DUT.	Pomeranezu, RUS.
Oranges, FR.	Naga-runga, Swadoo Naringa, SANS.

Narungee, PERS.	*Faulkner, Ainslie.*

The parts used are Aurantium Fructus, Aurantii Flores, L. Aurantii Oleum; L. Volatile Oil of the Flowers, Neroli Oil. E. Aurantii Aqua; Orange Flower Water, E. Fructus succus et tunica exterior. Flores. Folia, D. Like the Lemon, this is a native of India, being found in the forests on the borders of Silhet, and also on the Nielgherries, perhaps also in China. The Sanscrit *Nagrunga* and the Arabic *Narunj* are no doubt the European names of *Naranja* (Spanish), *Arancia* (Italian), whence we have *Aurantium* and *Orange*. The orange is not mentioned either by the ancients or the Arabian medical authors. It is supposed to have been introduced into Europe after the middle ages. The Orange-tree attains a height of 16 or 20 feet and bears great abundance of fruit. It is remarkable, as well as others of the genus, for bearing the fruit at all ages at the same time with the flowers. Though a native of India, it does not ripen its fruit there until the winter, and hence has been able to travel so much further north than others of its compatriots. Leaves coriaceous, ovate-oblong, acute; margins usually finely toothed; petioles margined, sometimes winged. Petals 5, white. Stamens about 20, 5 of them often distinct and appressed against the stigma, the remainder in 5 bundles alternating with them. Fruit globose, rind thin, with convex oil vesicles, adhering loosely to the pulp, which is sweet. Oranges are cultivated in the south of Europe and in the Axores, whence they are largely imported into England. The parts which are officinal are the flowers, L. D., and their essence, L.. also called Neroli Oil and distilled water, E. Juice of the Fruit and leaves. D.

Aurantii Folia. Leaves of the Orange are officinal in the D. P. on account of their bitterness and the aromatic properties of the essential oil stored up in the vesicles with which their substance is studded. This essential oil may be obtained by distillation, as also a distilled water. Or an infusion of the leaves may be employed as a bitter and aromatic excitant and diaphoretic.

Aurantii Fructus. The ripe fruit of the Orange is well known for its extremely agreeable and refreshing juiciness, whence it is so much esteemed as a fruit even for the sick, and as a refrigerant. When of a small size, the fruit which falls off is dried, and forms the *Aurantii baccæ* or Curacoa Oranges, so called from being employed in flavouring Curacoa. The smaller ones are smoothed, and used for making issues. The rind or peel for the fruit is sometimes substituted for that of the Bitter Orange, as are also the flowers and their essential oil, also the oil expressed from the grated rind, likewise Orange flower water; all being used for the same purposes as those produced from the Bitter Orange.—*Royle.* One variety of the orange fruit (of which there are various sorts) is in high estimation amongst the tamool Medical Practitioners, who suppose that it purifies the blood, improves the appetite and cures Catarrh.—*Ainslie.* The wood of the Orange tree is not available of any size, or in any quantity—*M. E. J. R.* This tree is now extensively cultivated all over the Deccan. The finest sorts are the Cintra, Cowlah, and a small sweet orange which grows on a tree more like a creeper. The principal method of culture is by budding, the stocks generally being either seedlings or cuttings from the sweet lime. The best Cintra, with a thin close rind, is produced upon the seedling stock, and it is said that the fruit grown upon the sweet lime stock is generally loose and soft: this is very perceptible with some of the oranges. The best time for budding is in the cold season.—*Riddell.* The leaves are rather bitter, and contain essential oil. A still more fragrant oil, called oil of *neroli* by perfumers, is afforded by the flowers. The berries while unripe are gathered, dried, and turned in the lathe to the size of peas, and are usedi n issues on account of their fragrant odour. The

rind or peel of the orange is bitter and aromatic, and affords a very useful stomachic tincture and syrup. The juice of the ripe fruit contains sugar, malic and citric acids, citrate of lime, mucilage, albumen and gum. Like the lemon juice it makes an excellent cooling drink, and is an invaluable specific in the treament of scorbutic diseases. The seeds of the orange yield oil by expression.—*O'Shaughnessy.* In Tenasserim Oranges are quite abundant, but for the want of proper attention they are much inferior to the West India oranges, and to those cultivated in the South of Europe. The trees are often exceedingly prolific. A seedling planted, produced in the ninth year more than two thousand oranges. —*Mason.*

(5897) ORANGE-DYE PLANTS. The flowers of the buteas with an alkali, the corolla tubes of the tree of mourning, and the leaves of the henna tree, yield beautiful orange dyes. The latter are used in India to dye skins a "reddish-yellow."—*Mason.*

(5898) ORANGE-TREE. The orange, lemon and lime trees (Citrus,) are evergreens that seldom exceed about 15 feet in height. The wood is only met with as an object of curiosity; it is of a yellow colour, but devoid of smell.—*Tred.*

(5898) ORANGE WINE (*Auranta*) prepared by Mr. Rundall, Razole, Rajahmundry District, is quite a novelty, and is an agreeable beverage. On being tasted, it was found sound and good, although of a somewhat peculiar flavour, resembling Malmsey or Muscat. It is recommended for flavouring jellies. The jury at the Madras Exhibition considered the manufacturer is deserving of a second class Medal.—*M. E. J. R.*

(5899) ORANG-UTAN, OR ORANG-OUTANG, names by which the *Pithecus Satyrus* of Geoffroy (*Simia Satyrus* of Linnæus), the Red Orang, is now generally designated. [APE; CHIMPANZEE.] The following are its generic characters:—Muzzle large, elongated, somewhat rounded anteriorly; forehead sloping backwards slight supraciliary ridges, but strong sagittal and lambdoidal crests. Facial angle 30°. Auricles small. Twelve pairs of ribs; bones of the sternum in a double alternate row. Arms reaching to the ankle-joint. No ligamentum teres in the hip joint. Feet long and narrow; hallux not extending to the end of the metacarpal bone of the adjoining toe; often wanting the unguical phalanx and nail. Canines very large, their apices extending beyond the intervals of the opposite teeth. Intermaxillary bones anchylosed to the maxillaries during the second or permanent dentition. Height under five feet. It is an inhabitant of the islands of Borneo and Sumatra (*Owen.*) Professor Owen remarks that the young individual exhibits the anthropoid character in the relative smallness of the face to the cranium, resulting from the state of dentition, but that it corresponds with the adult skeleton in the number of ribs and in the relative proportion of the and lower exteremities. With regard to the number of vertebræ, he observes that the figure of the adult skeleton, which was taken by permission of the board of curators from the specimen in the Museum of the Royle College of Surgeous, exhibits the abnormal number of five lumbar vertebræ instead of four, which is the number existing in the trunk of the mature Orang preserved in the Museum of the Zoological Society of London, and in the Skeleton in the Museum of Comparative Anatomy in the Jardin-des-Plantes. The form of the living animal, and its habits in captivity, have been made familiar by several specimens which have been kept in the Zoological Gardens.—*Eng. Cyc.*

(5900) ORCHIDACEÆ, a natural order of Endogenous Plants, with the stamens and style consolidated into a central column, and with an inferior ovary: they constitute the whole of the class *Gynandria monandria* of the Linnæan classification. There is no order of plants the structure of whose flowers is so anomalous as regards the relation borne to each other by the parts of reproduction, or so singular in respect to the form of the floral envelopes. [ONCIDIUM.] Unlike other endogenous plants, the calyx and corolla are not similar to each other in form, texture, and colour; neither have they any similitude to the changes of outline that are met with in such irregular flowers as are produced in other parts of the vegetable creation. On the contrary, by an excessive development and singular confirmation of one of the petals called the labellum or lip, and by irregularities either of form, size, or direction of the other sepals and petals, by the peculiar addition of these parts to each other, and by the occasional suspression of a portion of them, flowers are produced so grotseque in form that it is no longer with the vegetable kingdom that they can be compared, but we are forced to search for resemblances in the animal world. Hence we have such names among orchideous plants as the Bee, Fly, Man, Lizard, and Butterfly Orchis, and appellations of the like nature in foreign countries. Of these things some idea may be formed by the *Oncidium raniferum*, or the Frog-Oncidium, so called because its lip bears at its base the figure of a frog couchant; 2, *Peristeria elata*, the Spirito Santo Plant of Panama, in whose flowers we find the likeness of a dove in the act of descending upon the lip; 3, *Prescottia colorans*, whose lip is a fleshy hood; 4, *Gongora fulva*; 5, *Cirrhæa tristis*; 6, *Cycnoches ventricosum*, singularly like a swan, the arched column forming the head and neck; 7, *Oncidium pulvinatum*; 8, *Bolbophyllum barbigerum*; 9, *Catasetum viride*; and 10, *Peristeria cerina*. In consequence of their singular forms, their

gay colours, and the delicious fragrance of many of these plants, they have of late years been cultivated with great zeal, [EPIPHYTES.] Orchidaceous plants inhabit all parts of the world, except those which are excessively dry or excessively cold, both of which appear uncongenial to their nature; and they are most abundant in such as have an equable, mild climate, moist and warm during the greater part of the year. Thus we have not a single species from Melville Island, or Nova Zembla, or from the upper regions of northern mountains, nor from the deserts of Africa; and the whole province of Mendoza, one of the dry western states of South America, produces but one, and that in a marsh. On the contrary, the woods of Brazil and equatorial America, of the lower ranges of the Himalayas, and of the Indian Archipelago, possess countless myriads of these productions. In general, in hot countries the species are epiphytes, inhabiting the branches of trees, or the sides of rocks and stones, to which they cling by means of long twisting fleshy roots; and terrestrial species, that is to say, such as grow exclusively in the ground, are rare and unknown: in colder countries, on the contrary, the former are unknown and the latter only represent the order. Thus in North America, where Orchidaceous Plants are plentiful, the epiphytal species are almost unknown, a single species only occurring in Florida upon the branches of the *Magnolia*. Some of them are true parasites, deriving their food from the roots of trees upon which they grow. In England there are two cases of the kind, one the *Neottia Nidus-Avis*, or Bird's-Nest Orchis, a brownish scaly plant springing up occasionally in woods, and the other the *Corallorhiza innata*, or Coral-Root, an occasional but very uncommon inhabitant of marshes.

The differences in the structure of the column, anther, and pollen furnish botanists with the best means of classifying the order, and of breaking it up into sub-orders, in the following manner: —

1. *Malaxideæ* (*fig.* 1), anther opercular; pollen waxy, with neither caudicula nor gland.

2. *Epidendreæ* (*fig.* 2), anther opercular: pollen waxy, with the caudicula folded back upon the pollen grains, and no gland.

3. *Vandeæ* (*fig.* 3), anther opercular; pollen waxy, with a membrano-cartilaginous caudicula and gland.

4. *Ophrydeæ* (*fig.* 4), anther erect; pollen sectile or granular.

5. *Arethuseæ* (*fig.* 5), anther opercular; pollen granular or powdery.

6. *Neottieæ* (*fig.* 6), anther dorsal; pollen powdery.

7. *Cypripedieæ*, anthers two, separated by a broad sterile lobe. This order contains 394 genera and about 3000 species.—*Eng. Cyc.* Orchideæ are, perhaps, the largest natural order in the Khasia Hills where fully 250 kinds grow, chiefly on trees and rocks, but many are terrestrial, inhabiting damp woods and grassy slopes. I doubt whether in any other part of the globe the species of orchids out-number those of any other natural order or form so large a proportion of the flora.—*Hooker, Vol.* II. *page* 281. Fortune says, that having landed "I made the best of my way to the farm of Don Inego Gonzales de Azaola, whom I had met in Manila, and who had kindly offered me the use of his house in the interior. My chief object in visiting this part of the country was to procure, if possible, a supply of the beautiful orchid (Phalœnopsis amabilis), which Cumming had sent home a few years before, but which was still extremely rare in England. His Grace the Duke of Devonshire purchased the first plant, for which he gave the large sum of one hundred guineas. As I had very little time to spare, I was anxious to make the most of my opportunities. I made an Indian's hut in the wood my head quarters where I held a sort of market for the purchase of orchids. The Indians knew the hour at which I should return to the hut, and on my arrival I generally found the ground in front strewed with orchids in the state in which they had been cut from the trees, and many of them covered with flowers. The Phalœnopsis, in particular, was singularly beautiful. I was very anxious to get some large specimens of the plant, and offered a dollar, which was a high sum in an Indian forest, for the largest which should be brought to me. The lover of this beautiful tribe will easily imagine the delight I felt, when, one day I saw two Indians approaching with a plant of extraordinary size having ten or twelve branching flower-stalks upon it and upwards of a hundred flowers in full bloom. "There," said they, in triumph, "is not that worth a dollar?" I acknowledged that they were well entitled to the reward, and took immediate possession of my prize. This plant is now in the garden of the Horticultural Society of London; and although it was a little reduced, in order to get it into the plant case at Manila, is still by far the largest specimen in Europe. This beautiful species may be well called the "Queen of orchids." The air-plants are not found so frequently in the dense shaded parts of the Forests as in the edges of the woods, on trees by the road sides, and in exposed situations. I found the genus Aerides very often in the most dense parts of the woods, but never a single plant of Phalœnopsis. The latter was commonly found growing on the branches of the Mango in the cleared parts of the woods, near the cottages of the Indians, and sometimes on the very tops of high trees where it was fully exposed to the sun. I confess this fact was quite contrary to the opinion I had formed of the habits of these plants; for I expected to have found them principally in damp shaded forests, where the sun's

rays could seldom penetrate, but such is not the case, at least in the Philippine islands. With the exception of the orchids, the Philippines are not very rich in plants of an ornamental kind. As far as I had an opportunity of judging, the vegetation of Luzon bears a great resemblance to the island of Java, and the other parts of the Malay Archipelago. The country is however very rich in birds and shells, and many of the land species of the latter are extremely valuable. Mr. Cumming, who is well known in this part of the world, made very large collections of them and has already distributed them over the greater part of Europe and America."—*Fortune's Wanderings, p.* 381.

(5901) ORCHILLA WEED. ARCHILL, ORCHELLA.

Orseille, FR.	Oriecllo, Orcella, IT.
Orseille, GER.	Orchilla SP.

A whitish lichen (*Lichen orcella*) found in Guernsey, Portland Island, but chiefly obtained from the Canary, Cape de Verde, and Madeira Islands. It grows on rocks about three inches in length, roundish, and many stalks proceed from one root. This weed yields a rich purple tincture, used chiefly in dyeing silks and ribbons, but rarely employed alone, on account of the fugitive nature of the colour. Litmus is a preparation of orchill in square cakes. *Waterston.* Orchilla weed is imported into Bombay from Zanzibar, and is exported to England.—*Faulkner*

(5902) ORCHIS, a genus of Plants the type of the natural order *Orchidaceæ*, and belonging to the tribe *Ophrydineæ*. The old Linnæan genus *Orchis* is now divided into many genera [ORCHIDEÆ], but a large number of species are still retained under this designation. The tribe *Ophrydineæ* is distinguished by the pollen masses being divisible into lobes, which are waxy and definite in number. The anthers are wholly adnate. The genus *Orchis* belongs to a section of this tribe, in which the cells of the anther have a rostellate process between their bases. In *Orchis* the perianth is ringent and hooded; the lip 3-lobed, spurred; the glands of the stalks of the pollen-masses are in a common pouch.—*Eng. Cyc.*

(5903) ORCHIS COMMELINÆFOLIA. —Root of two or more spindleshaped succulent tubers; scape erect, about eighteen inches high; round, smooth-jointed; with cylindric sheathes, about half the length of the joints. Flowers white, scentless; appear about the middle of the rains on pasture lands in the Southern Concan. Several species are found on the hills.—*Riddell.*

(5904) ORCHIS MASCULA. The Salep plant, is found on the Mahabuleshwar hills. It blossoms in June, and the roots are dug up and gathered after the rains in November or December. Another variety is found in the hills and jungles near Candeish, but possessing a very bitter principle. It is dug up by the Bheels, and sold when fresh for a few pice the seer. It requires a great deal of soaking and preparation before it can be deprived of its bitter quality. When dry, it is in appearnce as fine as the Persian. It requires being boiled in at least six different waters, and then dried in the sun, when it will become perfectly sweet and fit for use. —*Riddell.*

(5905) OREODAPHNE, Mountain Laurel (from ὀρειος, mountainous, and δάφνη, a laurel), a genus of Plants belonging to the natural order *Lauraceæ*. It is hermaphrodite, diœcious, or polygamous, with a 6-parted nearly equal calyx, the limb eventually disappearing. It has 9 stamens, oblong anthers, with narrow filaments, 4-celled, the three inner looking outwards. The fruit is succulent, more or less immersed in a deep thick cup formed out of the altered tube of the calyx. The flowers are panicled or racemose, axillary, and occasionally umbellulate — *Eng. Cyc.*

(5906) OREODAPHNE CUPULARIS, is a very large tree with a strong-scented wood; it has ovate elliptical leaves, acute at both ends, sometimes blunt at the apex, ending in a chanelled stalk, obsoletely netted, smooth; the axils of the costal veins without pores. The flowers are in clustered few-flowered rough hoary racemes below the axillary and terminal bud. The calyx of the fruit is nearly globose. This species is the cinnamon of the Mauritius, where it grows, and also in Bourbon and Madagascar.—*Eng. Cyc.*

(5907) ORIGANUM from ὀρίγανον), a genus of Plants belonging to the natural order *Labiatæ*, or *Lamiaceæ*. It has an ovate tubular calyx, 10-13 nerved, striated, with nearly 5 equal teeth, the throat villous inside. The corolla has a tube equal in length to the calyx; the upper lip sub-erect, emarginate; the lower spreading, trifid, with nearly equal lobes. There are 4 protruding stamens, somewhat didynamous. The lobes of the style are nearly equal. The species are herbs.—*Eng. Cyc.*

(5908) ORIGANUM CRETICUM. (Linnæus) is the Ὀρίγανον of Hippocrates, 'Morb. Mul.,' 1, 6 9; the Ὀνήτις of Dioscorides, 3, 30; and the Λευκὸν ὀρίγανον of Theophrastus, 6, 2.

(5909) ORIGANUM DICTAMNUS. the *Amaracus dictamnus* of Benthan: the Δίκταμνος κρητικὸς of Hippocrates; the Δίκταμνον of Theophrastus, 'Hist. Plant.,' 9, 16; and the Δίκταμνος of Dioscorides, 3, 37. It has almost sessile leaves, clothed with dense wool on both surfaces as well as the branches. The leaves are broad, ovate-obtuse, quite entire, rounded at the base; the floral leaves are small, almost glabrous. The corolla purple, without a spur. The heads of the flowers nutant.—*Eng. Cyc.*

(5910) ORIGANUM HERACLEOTICUM is a very variable species, but is recognised by the bracts being longer than the calyxes, by the loose spikes, and small flowers. The stamens are more

or less villous, the leaves pale-green, glabrous, or pubescent. The flowers are white and one-half the size of the preceding species. This, the Winter-Sweet Marjoram, seldom ripens seed in this country, and is propagated by slips and cuttings. It requires a dry and sheltered situation. It is a native of the region of the Mediterranean, Greece, and about Odessa on the Black Sea. It has an aromatic sweet flavour, and is much used as a relishing herb in cookery. This is the *Culina gallinacea* of Pliny, 20, 16; Cato, De Re Rustica,' c. 127; Seren. v. 909; and the 'Ορίγανον ἡρακλεωτικὸν of Dioscorides, 3, 29.

(5911) ORIGANUM MARJORANA, of Linnæus.

Murwa, Duk. | Maroo, Tam.

A native of India, very easily reared in beds or pots, either by slips from the roots, or seed. It is used for flavoring sauces, &c. This delicate sweet smelling plant the Hindoos offer at the shrines of Vishnoo and Sheva. —*Jaffrey*. Is the *Marjorana hortensis* of Moench, and the 'Αμάρακον of Theophrastus, 'Hist, Plant.' 6, 7; the Σάμψυχον of Dioscorides; 3, 41. It has nearly glabrous racemosely panicled branches, petiolate oblong-ovate leaves clothed with heavy tomentum on both surfaces, oblong sessile spikelets glomerate on the branchlets. This plant is a tree or shrub in its native country, but an annual in our gardens It is native of the North of Africa near Mascar, on hills, and of Asia, on the mountains of Kumaon. The bracts and calyxes are complanate, closely imbricate. The corollas small, purplish or white. As the seed seldom ripens in England, it is generally procured from France. When in blossom, the plant is cut and dried for winter use, as a savoury ingredient in cookery.—*Eng. Cyc.*

(5912) ORIGANUM SMYRNEUM VEL SYRIACUM. Is the 'Τσσωπος of Dioscorides, 3, 27. and of Hippocrates, 'Morb. Mul.,' 3. 490. The ancient plant is usually referred to *Hyssopus officinalis*, but according to Fraas this plant does not grow in Greece, Asia Minor, or Syria. *O. sipyleum* of Linnæus is the Μάρον of Dioscorides, 3,42.

(5913) ORIGANUM VULGARE, Marjoram, has stalked ovate-obtuse leaves, ovate bracts longer than the calyx, the heads of the flowers roundish, panicled, and crowded. The bracts are usually purple, ovate-obtuse, and at least half as long again as the calyx. It is a native of Great Britain in dry uncultivated places, and of Europe, North of Africa, and of Middle Asia and America. It is an ornamental and aromatic plant, and yields what is sold as oil of thyme in the shops, a common remedy for toothache It is frequently mixed with olive oil as a stimulating liniment against baldness, in rheumatic complaints, and against strains and bruises. The dried leaves used instead of tea are very pleasant; they are likewise employed in fomentations. The essential oil is so acrid that it has been used by farmers as a caustic. It is the 'Ορίγανον μέλαν of Theophrastus, lib. vi., cap 2, and the 'Αγροφίγανος of Dioscorides, 3, 31.

(5914) ORMOCARPUM SENNOIDES, Hedysarum sennoides of Roxburgh.

Kanana, Sans. | Junglee moonghee, Hind.

Root considered tonic and stimulant.—*O'Sh. page* 317.

(5915) ORNITHOLOGY, the science which teaches the natural history and arrangement of Birds. This term is derived from the Greek words Ορνις, a bird, and λόγος, a discourse; signifying literally 'a discourse upon birds.' [Birds.]

(5916) OROBUS. Fischeri. Bitter Vetch.—Readily cultivated from seed in any good soil, colours various.—*Beg. Banopsha Per. Riddell.*

(5917) OROBANCHE (from ορομβυς, a kind of vetch, and ἄγχω, to strangle, because its species grow on the roots of vetches, and were supposed to destroy them by strangulation), a genus of Plants, the type of the natural order *Orobanchaceæ*. It has 2 lateral, undivided or cloven permanent sepals; a ringent withering corolla, the upper lip concave, notched, the lower reflexed, in three unequal wavy lobes; a gland under the ovary; the anthers sagittate with the lobes pointed at the base; the filaments almost as long as the tube of the corolla, downy and glandular; the capsule ovate, pointed, with four parietal parallel placenta. The species are parasitical, usually simple, rarely branched, scaly erect herbs. Eleven species of this genus are British.—*Eng. Cyc.*

(5918) ORRIS ROOT, Iris Florentine.

Ussul-ul-sosun-ul maa joonie, Isra, Arab.	Violen wurzel, Ger.
Iris de Florence, Fr.	Ireos, It.
	Kewra-ka-jur, Guz. Hind.

Is obtained from the south of Europe and Asia Minor. It is tuberous, oblong, about an inch thich, white, odour like that of violets, taste when dry, bitter. An inferior description of orris root is imported into Bombay from the Persian Gulf, which is procurable in most bazars. Orris root is used by perfumers, and in medicine.—*Faulkner.*

(5919) ORSIDUE, Brass Leaves, Dutch Leaf or Gold, Flittergold, Manheimgold.

Klatergoud, Dut.	Orpelio, It.
Oripeau, Oliquant, Fr.	Oropel, Sp.
Flittergold, Ger.	

An article resembling gold leaf, made of copper and zinc, and largely used in tinselling dolls, toys, images, &c. It is made up into books, and in this state is packed in casks and cases for exportation from Manheim in Germany, where it is chiefly manufactured. —*Faulkner.*

(5920) ORTHANTHERA VIMINEA is a plant of the family *Asclepiadeæ* well calculated to yield fibre. Dr. Royle found it growing at the foot of the Himalayan Mountains—'*Himmalayan Botany*,' p. 274. It attains a height of ten feet, and is also remarkable for the length and tenacity of its fibres. This grows luxuriantly along the foot of the mountains; and its long, straight, leafless, slender, and wand-like stems, point it out as seemingly well suited for rope-making."—*Royle. Fib. pl. p.* 1306.

(5921) ORTOLAN, the French and English names for a species of Bird belonging to the family *Fringillidæ*, much esteemed by epicures for the delicacy of its flesh when in season. It is the *Hortulanus* of Gesner and others, *Miliaria Pinguescens* of Frisch, *Emberiza hortulana* of Linnæus, Ortolano of the Italians generally, Tordino Berluccio of the Venetians, Garten Ammer and Fellammer of the Germans, and Gerste Kneu of the Netherlanders. Willughby writes the name Hortulane; and Montagu terms it the green-Headed Bunting. [EMBERIZIDÆ] This bird is found in the south of Europe, which may be considered the summer and autumnal head-quarters of the Ortolan, though it is a summer visitor in the central and northern parts. In Italy it is said to be common, by Temminck and others. Prince C. L. Bonaparte states that it is found in the Sabine Mountains, but not commonly, in the summer, and that it rarely occurs in the plain of Rome, but is frequent in Tuscany. India, Lapland, Russia, Denmark, Sweden, and Norway, are among the countries visited by it. In Britain it seems to be only entitled to rank as an accidental visitor, but it is by no means clear that it does not occur more frequently than is generally supposed: for, especially to an unpractised eye, it might be mistaken for the Yellow-Hammer, and in some states of its plumage for other Buntings. It has been taken in the neighbourhood of London; and one of these specimens was alive in 1837, in the aviary of the Zoological Society in the Regent's Park. Bewick's figure ('Green-Headed Bunting,' last edition, Supp., p. 24) was captured at sea off the Yorkshire coast, in May, 1822. In southern Europe it is common from May to August, and every spring and autumn may be observed at Gibraltar on its migration. Mr. Strickland saw it at Smyrna in April. North Africa is its winter residence. Colonel Sykes notes it in his 'Catalogue of the Birds of Dukhun' (Deccan). When properly fed, for which purpose there are large establishments in the south of Europe, where they are placed after having been trapped and furnished with plenty of millet-seed and other grain, till they become sheer lumps of fat, they are delicious morsels. Mr. Gould states that this is effected in Italy and the south of France in a dark room. Prince C. L. Bonaparte says, "Nella vicina Toscana, dove gli Ortolani sono frequenti, si mantengono nelle Uccelliere illuminate giorno e notte finché restino soffocati dalle pinguedine." (In the neighbouring districts of Tuscany, where the Ortolans are numerous, they are kept in aviaries which are illuminated day and night, where the birds are fed till they are suffocated by their fatness), and he adds the relishing words, "carne squisita" (flesh exquisite).—*Eng. Cyc.* A kind of lark called an Ortolan was found by Dr. Hooker in the Parwah district. He says abundant; this is not, however he says the European delicacy of that name, though a migratory bird; the flocks are large, and the birds so fat, that they make excellent table game. At this time they were rapidly disappearing; to return from the north in September.—*Hooker. Him. Jour. Vol.* I. *page.* 98.

(5922) ORYZA, a genus of Plants belonging to the natural order of Grasses. It is the name by which rice was known to the Greeks and Romans, and which has been adopted by botanists as the generic name of the plant yielding that valuable grain. The Greek name would appear to be derived from the Arabic Aruz, and this is allied to Uri, the Telinga name of cultivated sorts; but the Sanscrit names are Unoo, Dhanya, and Vrihi; the wild kind being called Nivara, while that of the great tanks is called Arizee in the Tamul language. The European names are evidently all derived from the same sources, but the name Paddy is applied to the rice in its natural state, or before being separated from the husk. The natives of India call it Dhan in this state, as well as the plant, and the rice itself is called Chanwul. The genus *Oryza* has two glumes to a single flower; palea two, nearly equal, adhering to the seed; stamens six, and styles two. Dr. Roxburgh describes two species; one, *O. sativa*, distinguished by its diffuse panicle; the other, *O. coarctata*, has the panicle contracted, the valvulets of the calyx subulate, and the leaves culm-clasping. This species is a native of the delta of the Ganges, and was first discovered there by Dr. Buchanan in 1796, but was not found to be applied to any use. The Common Rice, *O. sativa*, unlike many long cultivated grains, is still found in a wild state in and about the borders of lakes in the Rajahmundry Circars of the Peninsula, though never cultivated, because the produce is said to be small compared with that of the varieties in cultivation. [RICE, in ARTS AND SC. DIV.]

(5923) ORYZA SATIVA RICE. Lin.

Arisee, TAM.	Beeum, TEL.
Chawul, HIND. & DUK.	Brass, MALAY.

This appears to be indigenous in the upper provinces of Hindoostan.—*Ainslie. p.* 217.

(5924) ORYZA SATIVA. Var.

Adypilloo Arisee, TAM.

This grain is found in uncultivated tracts of the Southern parts of the Peninsula, and is said to be

eaten only in times of great scarcity.—*Ainslie. p.* 217.

(5925) ORYZA SATIVA. Var.

Amalay Arisee, Tam.

This small grain is never brought to market, nor have I ever seen it growing: it is said to be met with in the Ramnad country and to be eaten by the poor only, in times of scarcity.—*Ainslie. p.* 217.

(5926) OSBECKIA. A pretty species of osbeckia having the stamens all of equal length, is in flower on the Maulmain hills in August. —*Mason.* Dr. Wight gives Osbeckia aspera, 377; Gardnerina, 997; hispidissima, 1612; Leschenaultiana, 996; truncata, 375, 996; virgata, 376; Wightiana, 927-8.

(5927) OSSARA REWUND, See Gamboge.

(5928) OSTEOCOLLA. The term applied to an inferior kind of glue, manufactured from bones.

(5929) OSYRIS WIGHTIANA, Santalaceæ. The Lotel. A small tree with twiggy erect growing branches; in flower and fruit most of the year. The fruit when ripe is of the size of a small sloe, of a yellow color, with a mark on the top like a "blaeberry." It is sweet and very pleasant when tasted, and is deservedly ranked amongst the wild fruits by Col. Sykes.—*Riddell.* Dr. Wight gives *Osyris peltata*, 817-1883; and Wightiana, 1853.

(5930) OTTER. The common Otter of India, and any of the others of this country (so far as is known), is not identical with the European Otter; but in the museum of the Asiatic Society there is a specimen of an Otter from Algeria, which (externally at least) is undistinguishable from the common Otter of Bengal, that is so extensively tamed and *trained* along the course of the Brahmaputra, as Cormorants are also trained in China.—*Bligh.*

(5931) OTTO OF ROSES.

Utter, Guz. | Uttur-i-Gul, Per.
Gulab-ka-Uttur, Hind.

This far-famed, highly valuable, and delightful perfume, is prepared in Persia, Upper Egypt, Tunis, Cashmere, and Ghazipore in Bengal. It is estimated that one hundred thousand roses, yield 189 grains or one tola of the utter. The otto of roses purchased in the bazars is generally adulterated with sandalwood and sweet oil; the genuine article being only procurable at a high price.—*Faulkner.*

(5932) OTIS TARDA. Bustard

Neel naray, Tam. | Beetmiakie, Can,
Jungliekaboot, Hind. | Cowdun, also Jerz, Pers.
Beetmiaka, Tel.

Various species of this genus of birds are to be met with in many parts of India, but the *O. tarda* is more rarely seen, in the lower and southern tracts of the Peninsula, than in the more northern regions. In Mysore, which, from its great elevation, is much colder than other countries of the same latitude, the Bustard is still common. —*Ainslie's Mat. Med p.* 296. Bustard is the English name of a bird belonging to the genus Otis. The species are land birds whose proper position in the ornithological system has caused some embarrassment to Zoologists.—The Bustards live generally in open countries, preferring plains or wide-spreading extensive downs dotted with low bushes and underwood-localities which give them an opportunity of descrying their enemy from afar.—They are found in Europe, Asia, and Africa; but not in America. The *Otis tarda*, the great Bustard, is the *Otis* and *Avis tarda* of Belon and others; Ostarde Houtrade, Outarde, Bistarde of the French; Starda and Starda commune of the Italians; Der Grosse Trappe, Trapp, Trappgans, and Ackentrapp of the Germans; Abutarda (*Aris tarda*) of the Spaniards; and Gustard of the old Scotch. The *Otis nigriceps* is a native of Asia. The specimen from which the figure in Mr. Gould's magnificent work ('Century of Birds from the Himalaya mountains') was taken, was brought from the highlands of the Himalaya, but it is by no means confined to that locality. Colonel Sykes observed it in the wide and open country of the Mahrattas, where it lives in large flocks, and where it is considered one of the greatest delicacies as an article of food. It was indeed so abundant in the Deccan, that Colonel Sykes records, in the 'Proceedings of the Zoological Society,' that one gentleman shot nearly a thousand. The male has the body above pale bay, lightly undulated with rufous-brown; neck, a few spots on the wings, and belly, white; the head, which is crested, the outer wing-coverts, the quills, and the large mark on the breast, black; irides deep-brown; bill and feet yellowish. Length, inclusive of tail, 56½ inches; tail, 13½ inches. The female resembles the male in plumage, but is only 41½ inches including the tail, which is 10½ inches. The eggs, of which Colonel Sykes found only one in a hole in the earth on the open plain and that considerably advanced in the process of incubation, were in shape a perfect oval, and in colour a brown-olive, with obscure blotches of darker brown olive. Length 3 $\frac{4}{10}$ inches, diameter 27 inches.—*Engl. Cyc. page* 701.

(5933) OVEÆ (Gray). a sub-tribe of the tribe *Bovina* and family *Bovidæ*. It includes the common Sheep and allied species. The following is Dr. J. E. Gray's definition of this family:—Forehead flat or concave. The horns are more or less spiral, wider than deep at the base, and slightly annulated in front. The females

are often horuless. The skull has a more or less deep rounded suborbital pit, without any fissure; the masseteric ridge ascending high before the orbit: the auditory bulla small; the basi-occipital flat, more or less expanded anteriorly by the extension of the anterior pair of tubercles, the posterior ones small; the cutting-teeth are nearly equal-sized and shelving; and there are no supplemental lobes to the grinders. The hoofs are triangular, and being shallow behind, they have distinct interdigital fossæ. Males emitting no stench. The Genera included in this family are—

(5934) OVIS, Crumen distinct. Tail elongated. Skin covered with wool or adpressed hair.

Caprovis. Crumen distinct. Tail very short. Skin covered with thick hair, covering the wool.

Pseudois. Crumen none. Tail rather elongated. Forehead convex. Skin covered with thick hair.

Ammotragus. Crumen none. Tail rather elongated. Forehead concave. Skin covered with short hair, and elongated tuft of hair.

(5935) OVIS ARIES, the Common Sheep, is subject to great variety, and many of its forms have been raised to the rank of species. Dr. Gray, in the 'British Museum Catalogue,' enumerates no less than 33 varieties of this species.

The following is a list of the varieties from the 'British Museum Catalogue':—

The Spanish Sheep. It is the *Ovis Hispanicus* of Linn.; called also the Merino Sheep and the British Middle-Wooled Sheep.

The Common Sheep (*Ovis rusticus*, Linn.; *O. Gallica* Desm.; *O. brachyurus* Pallas; *O. leptura*, Schreb.): the Horuless Sheep (*O. Anglicana*, Linn.). Of this variety there are numerous forms, such as the Muggs Sheep and Shetland Sheep, the Southdown Sheep, the Old Lincoln Sheep, the Romney Marsh Sheep, the Cobwold Sheep, the New Leicester Sheep, the Cheviot Sheep, the Old Teeswater Sheep, the Improved Teeswater Sheep, the Dunky Sheep, the Zetland and Orkney Sheep, the Welsh Mountain Sheep, the Soft-Wooled Sheep of Wales, the Wicklow Mountain Sheep, the Kerry Sheep, the Exmoor Sheep, the Black-Faced Sheep, the Black-Faced Heath-Sheep, and the Rass or Roosh (*Ovis Polii*, Blyth.)

3. The Barwall Sheep *Ovis* (*Aries Barwal* Hodgson); *Ovis Barwal*, Hodgson; *O. Ammonoides* var. 1, Gray. It inhabits Nepaul.

4. The Huniah Sheep (*Ovis Hunia*, Hodgs.); The Hoonia, or Black-Faced Sheep of Tibet Also a native of Nepaul.

5. The Cago (*Ovis Cagia*, Hodgs.) the Kago, or Tame Sheep of Cabul region; the Cago Sheep of Gray. A native of Nepaul.

6. The Seling. A native of Nepaul.

7. The Curumbar Sheep of Mysore.

8. The Sheep called Garar in India.

9. The Dukhun Sheep.

10. The Shaymbliar Sheep of Mysore.

11. The Broad-Tailed Sheep (*O laticaudatus*, Erxl., Geoff., 'Mem. Egypt,'; Lesson, 'Comp. Buffon,' x. 812; *O laticauda platyceros. Arabica*, Linn.; *O. Turcica*, Charlet; *O. cauda abesa* Ludolf), It is a native of Barbary. There are several forms of this variety, of which the following are most prominent:—The Fat-Rumped Sheep (*O. Steatopyga*, Pallas; the Tartarian Sheep of Bewick); the Persian Sheep *O. A. ecaudatus*, Geoff.); the Fat-Tailed Sheep (*O. A macrocercus*, Schreb.); the Aora Fivel, or Abyssinian Sheep; the Bucharian Sheep *O. Bucharica*, Pallas); the Tibetan Sheep *O. Thibetanus*, Fischer); the Cape Sheep *O. Capensis*, Erxleb.); the Sheep of Belkah.

12. *Many-Horned Sheep* (*O. polyceratus*, Linn.). It is also called the Four-Horned Ram, and the Dumba Sheep. It is a native of Nepaul.

13. The *puchia*, or Hindustan Dumba (*O. puchia*, Hodgson).

(5936) *Coprovis Vignei*, this genus embraces the Sha, or Koch. It is the Mountain Sheep of the North of India, and is found in Tibet.

C. Argalis, the Argali. It is the *Ægoceras Argali* of Pallas, and often confounded with the former. It is a native of Siberia. Dr. Gray says of this species—"The Nyens or Bambheras, or Wild Sheep, seldom or never cross the Hemachal, the Indian side of which range in the special habitat of the Nahoors, while to the north and west beyond Thibet, our animal is replaced by other species, so that Thibet may be considered as the special habitat of one species (*Ovis Ammonides*), and the plateaux north of Thibet as far as the Altai of another (*Ovis Ammon*), cited as types of the true ovine form; and it may be added, that the six sorts of tame sheep of Thibet and the Sub-Himalayas all without exception exhibit the essential characters of that form. "There are several species that may be confounded under this head: the Siberian Argali is found in the most northern part of that country, and it is probably different from the Himalayan animal; but I have not been able to discover any difference between the specimen received from Mr. Hodgson and those which were sent from Siberia by the Russian naturalist."—*Eng. Cyc.*

(5937) *Pseudois Nahoor*, the Nahoor, Nervate or Sua, is a native of Nepaul.—*Eng. Cyc.*

(5938) OVIS AMMON OF PALLAS, stands from four to five feet high, and measures seven feet from nose to tail. It is quite a Tibetan animal, is seen as high as 18000 feet and is seldom seen below 14000 feet except when driven lower by snow.—*Hooker, Vol. 1, p. 244.*

(5939) OVIS POLII, O. ammonoides, Capra hymalaica, C. jemblaica, were sent to the Paris Exhibition of 1855.—*Paris E. J. R.*

(5940) OXALIC ACID.

Sauerk-lees-aure, Ger.

A vegetable acid, found in considerable quan-

tity in sorrel and rhubarb. Accidents have frequently occurred from its being administered instead of Epsom salts, which it resembles in appearance. It is used in calico printing, and by straw-hat makers. It is an object of considerable importance in Switzerland, where it is prepared from the juice of wood-sorrel. Oxalic Acid is obtainable from the Salt in the leaves of Gram, Cicer Arietinum.—*Faulkner. Taylor.*

(5941) OXALIS (from ὀξύς, sharp, acid; the leaves have an acid taste), a genus of Plants belonging to the natural order *Oxalideæ* or *Oxalidaceæ*. It has 4 sepals connected below, and 5 petals which are likewise frequently connected below. The stamens are 10 in number, and monadelphous; the 5 outer ones shorter than the rest. The styles 5, and the capsules oblong and 5-cornered.—*Eng. Cyc.*

(5942) OXALIS ACETOSELLA, Common Wood-Sorrel, is a small perennial plant with a subterranean rootstock consisting of many scaly joints; the leaves are ternate, leaflets obcordate and having the peduncles longer than the leaves, with two scaly bracts at about the middle; the corolla is about 4 times as long as the calyx, and of a white colour beatifully veined with purple. Mr. Curtis remarks that the leaves are often purplish beneath, and that the fruit darts forth its seeds at the smallest touch when ripe. This species of wood-sorrel has a pleasant acid taste, dependent on the presence of oxalic acid, and is frequently used in salads; its flavour approaches near to that of lemons or tartaric acid, with which its medicinal effects also correspond, as it is esteemed a refrigerant antiscorbutic and diuretic. The expressed juice of this species, evaporated and set in a cool place, affords a crystalline salt, which may be used whenever vegetable acids are wanted. It is sold in the shops under the name of Essential Salts of Lemons, and is employed to take iron-moulds and ink-spots out of linen.

(5943) OXALIS CORNICULATA, Sorrel Yellow-Wood sorrel. Lin. (Three leaved sorrel.)

Pooliary keery, Tam.	Poollie chinta koora. Tel.—*Ainslie's Mat. Med. p.* 256.
Umbutie ke baujee, Duk.	
Shooklika, Sans.	
Umbuti, Duck.	Chukaika, Ambashta, Amilka, Sans.
Pallachinta, Tel.	
Amrool, Hind.	Chooka-tiputtee, Beng.

Oxalis Corniculate, Horned Wood-Sorrel, has a decumbent stem, branched and rooting; the leaves are ternate with obcordate leaflets; oblong stipules united to the base of the petioles; the peduncles are two-flowered, and shorter than the leaves. It is a native of Europe, particularly in Spain, Italy, and Greece, as well as of Japan, Mexico, North, America, and England. The flowers are yellow. The flowers of the North American plant are larger than the European. This species is common all over India, possesses exactly the same properties, and yields the same products as the European sorrel. The small leaves, tender shoots, and flowers, are given in electuaries by the Hindoos as a cooling medicine in fevers, the extent of two tea-spoonsful daily —*O'Shaughnessy, p.* 257. The stem of this plant is imported from Delhi: very sour: used to cure flatulent indegestion.—*Gen. Med. T. p.* 153. A common weed on lawns and in gardens—used by the natives in making chatney; and in curries, a good substitute for lime juice or tamarind imparting a peculiar acid taste.—*Jaffrey.*

(5944) OXALIS ROSEA. Tuberous rooted plants, from the Cape of Good Hope, easily cultivated at the commencement of the rains; the small tubers should be allowed to remain in the pots in which they have grown and be carefully removed into fresh earth after the rains have set in, and if well attended to, will readily spring up, and produce abundance of rose coloured flowers.—*Riddell.*

(5945) OXLEYA XANTHOXYLA, is a native of Australia. It attains a height of 100 feet. The wood is yellow, and employed for building boats. It is called yellow-wood. [Swietenia; Cedrela.]—*Eng. Cyc. page* 802.

(5946) OXYLOBIUM CORDIFOLIUM. These are ornamental plants, easy of culture, in any common soil; the colours are yellow, orange and scarlet.—*Riddell.*

(6947) OXYSTELMA ESCULENTUM. *Syn.* Periploca esculenta. Asclepias rosea.—*Roxb. Fl. Ind.* ii. *p.* 40. A twining perennial, deciduous plant, flowers in the rains, large white, with a slight tinge of rose colour, and streaked with purple veins; texture thin and delicate.—*Riddell.* Common in India on the banks of rivulets, used by the natives in decoction as a gargle in apthous ulcerations of the mouth, and in sore throat: cattle eat the roots. (*Royle.*)—*O'Shaughnessy, p.* 457.

(5948) OXYURA CRYSANTHEMOIDES. Native of Britain, and North America, cultivated in any garden soil.—*Riddell.*

(5949) OXYURA. Mountain sorrel.

(5950) OYSTER.

Huitre, Fr.	Seepee, Hind.
Austern, Ger.	Ostreæ, Lat.
Ostriche, It.	Ostras, Sp.
Kaloo, Guz.	

A well-known and generally diffused shell fish.—*Faulkner.*

(5951) OYSTER SHELL, See Mother of Pearl Shell.

P.

(5952) PABUT: PALOOD. In the Punjab and Cashmere, there are different kinds of white earths, which are used by the Hindoos under under the name of Pabood in the religious ceremonies. The genuine, what I got at Lahore was carbonate of magnesia combined with a very small quantity of oxyde of iron. I received an inferior kind in Cashmere, which was a product of the hills, namely, from Amernat, this earth was carbonate of lime and magnesia with very little oxyde of iron.—*Honigberger. p.* 321.

(5953) PACHYDERMATA (literally Thick-Hides; Dickhauter of the Germans; Pachyderm of the French), the seventh order of *Mammalia* according to the system of Cuvier.—*Eng. Cyc.*

(5954) PACHYRHIZUS, has a long compressed pod, with kidney-shaped seeds and no dissepiments, and is remarkable for its principal species, *P. angulatus* (formerly *Dolichos bulbosus*), producing a root of the size and substance of a turnip. It is reported to have been carried to the Pilippines from South America, and thence to have been introduced into the west of Asia. The side leaflets are nearly triangular, that in the middle lozenge-shaped, slightly toothed, and shaggy on both sides. The flowers are very beautiful, of a violet-blue colour, and arranged in axillary nearly erect racemes, from one to two feet long. Its root is a common article of food in the Malay Archipelago, but no other part of the plant is eaten.—*Eng. Cyc.*

(5955) PADDY.

Bhatt, Guz. & Hind.

A term applied to rice in the husk.—*Faulkner.*

(5956) PADDY BIRD FEATHERS are extremely light, soft, and delicate; resembling the down of the Eider duck. Their colour is white, sometimes slightly variegated with black. Muffs, tippets, and other similar articles, made of these feathers, are often brought from India, as presents.—*Comp. Desr.*

(5957) PADMAK. The wood of a tree from the Himalayas, considered to be refrigerant.—*Gen. Med. Top. p.* 149.

(5958) PÆDERIA, a genus of Plants belonging to the natural order *Cinchonaceæ*. It has a small 5-toothed permanent calyx, a funnel-shaped corolla, hairy inside, 5-lobed, and with a plaited æstivation. There are 5 stamens, sometimes abortive; the anthers oblong, nearly sessile in the middle of the tube. The style is not protruded, and the stigma bifid. The berry is small, roundish, and globose, tricelled, with a seed in each cell. The flowers are small, white, and usually unisexual.—*Eng. Cyc.*

(5959) PÆDERIA FÆTIDA.

Gundha-Badhalee. Beng. | Gundale, Hind.

Pæderia has a woody twining stem, round and smooth. The leaves are oblong or lanceolate, cordate at the base, and glabrous. The panicles axillary, terminal, opposite, short, and few-flowered. The flowers are usually of a deep pink, the bracts ovate, the calyx 5-toothed, the corolla with a long tube somewhat gibbous and woolly inside; the limb narrow and divided into 5-cordate crenulate segments. The berry is dry, compressed, having 5 lines on each side, 1-celled, and 2-seeded. The seeds are smooth, compressed, enlarged with a somewhat membranous ring all round. The leaves have a very fœtid and aliaceous odour when bruised, yet they are used to impregnate baths, and are administered in a decoction medicinally in cases of retention of urine and some febrile complaints. According to Roxburgh the root is used by the Hindoos as an emetic. It is a native of the East Indies, and of Japan and the Moluccas.—*Eng. Cyc.*

(5960) PÆDERIA TERNATA has an erect smooth trichotomous steam, with triangular branchlets; leaves 3 in a whorl; oblong-lanceolate axillary trichotomous corymbs shorter than the leaves; the limb of the calyx campanulate and obscurely 5-toothed. It is a native of the East Indies on the mountains which border on Silhet. The flowers are rather large, funnel-shaped white, on long filiform pedicels, each pedicel having a pair of linear ciliated bracts above the middle. The flowers are said to be fragrant when fresh, but emit a very offensive smell on being steeped in water after they have been dried.—Lindley, *Flora Medica.*—*Eng. Cyc.*

(5961) PÆONIA is a genus of Plants belonging to the natural order *Ranunculaceæ*. The species are very generally cultivated in gardens for the sake of their large gaudy flowers. They are characterised in their order by a permanent leafy calyx of 5 unequal sepals, 5 petals, stamens whose anthers split open by two fissures along their face, a fleshy elevated disc, and from 2 to 5 many-seeded carpels, terminated by a fleshy recurved stigma. Their fruit consists of leathery follicles, splitting on one side, and exposing to view a number of round, black, shining seeds adhering to a crimson placenta.—*Eng. Cyc.*

(5962) PÆONIA ARBOREA. These beautiful flowering plants, the herbaceous species of which are so generally cultivated in England, and thrive best in the conservatories, are not known in Western India. *Riddell.*

(5963) PÆONIA MOUTAN is a shrub, of which several varieties, with beautiful whitish flowers stained with pink, are now in British gardens. Of these the most showy is that called *P. papaveracea*, which has a broad crimson stain at the base of each petal. If grown on the north side of a wall, or in a situation where it is but little exposed to the sun in the early part of the day, this species will bear the open air of England without protection; but it sprouts so early in the spring, it exposed to the sun, that it is very liable to be cut off by the late frosts of England. It is a native of China. Of the other species, *P. Brownii* and *P. Californica* are remarkable for being the only species inhabiting America; they are natives of California and of the country to the northward, and have little beauty: the first exists in English gardens, but is extremely rare. The rest of the genus consists entirely of European and Asiatic plants, which, according to De Candolle, form fifteen species; but there can be no doubt that the greater part of these supposed species are mere varieties, chiefly of *P. officinalis*, *P. albiflora*, *P. tenuifolia*, and *P. peregrina*. All these plants are liable to produce double flowers, which, by the conversion of their numerous stamens into petals, are generally extremely beautiful: they have however no smell, or not an agreeable one. Being quite hardy, growing readily in any kind of soil, and easily multiplied, either by seeds or by division of the roots, they are generally favourites in gardens. All the species have an acrid principle concentrated in their roots and seeds, which are accordingly emetic and cathartic in moderate doses. They were formerly in great repute as a medicine; and Dioscorides, whose Παιονία was probably both *P. officinalis* and *P. peregrina*, gives no fewer than sixteen names, by which it was known.—*Eng. Cyc.* See MOUTAN.

(5694) PAGRUS, a genus of Fishes belonging to the family *Sparidæ*, with the following characters—Four or six strong concave teeth in front, supported by smaller conical teeth behind them, with two rows of rounded molar teeth on each side of both jaws. [PAGELLUS]—*Eng. Cyc.*

(5965) PAGURIDÆ, OR PAGURIANS, a tribe of the apterurous section of the Anomurous family of *Crustacea*, composed of a considerable number of species, the greater part of which are remarkable for the more or less complete softness of the abdomen, the want of symmetry in the appendages of this part of the body, the shortness of the two posterior pairs of feet, and many other characters. Modern writers recognise several genera of this family. The *Pagurus* of Aristotle is not a Hermit-Crab; but he describes three kinds of hermit-crabs under the name Καρκίνιον. They are termed Καρκίνας by Oppian, Ælian, and Galen.—A great resemblance exists among all the *Paguri*, *Pagurus* (Fabricius), properly so called, not only in the details of their organisation, but in their habits. The cephalo-thoracic portion of their body is shorter than the abdominal portion.—*Eng. Cyc.*

(5966) *Pagurus Deformis.* Ocular peduncles very stout and short, rather longer than the basilary portion of the external antennæ, but much shorter than the anterior border of the carapace; cornea large, and occupying half the length of the terminal joint of the ocular peduncles. Anterior feet short and stout, especially on one side, smooth externally but spiny above; a dentilated crest on the upper border of the large moveable finger. Succeeding feet smooth, and with but little hair, furnished externally with a projecting crest, which extends over the two first joints, and which, in the third foot, is very much developed and finely dentilated. Nothing similar on the opposite side. Abdomen furnished with four large transverse plates, each with an ovriferous false foot, the first three of these are large, and terminated by three elongated and ciliated laminæ in the female. In the male all these appendages are small, and terminated by a single lamina. Length 5 inches. It is a native of the Mauritius and the Seychelles.—*Eng. Cyc.*

(5967) *Cenobita* (Latreille).—This genus, in the opinion of M. Milne-Edwards, establishes the passage between the *Paguri*, properly so called, and *Birgus*.

(5968) *Cenobita rugosa.* Stomachal region nearly flat; labial border of the branchial regions very projecting, and slightly curved. Ocular peduncles nearly twice as long as they are high; their basilary scale moderate and pointed. Feet granulous and slightly muricated; the great claw moderate, and furnished above with a row of small, oblique, and parallel crests. Tarsi short and triangular. Upper and external edges of the two last joints of the third left foot elevated into an obtuse crest. Length about 3 inches. It is found in the Indian Ocean. There are three other species.—*Eng. Cyc.*

(5969) PAGUMA TRIVIRGATA.

SYN. Paguma trivirgata, Gray.
Viverra „ Reinward, Mus. Leyd.
Paradoxurus trivirgatus, Gray.

In Burmah, this animal is very common, and occasionally enters houses in the towns in pursuit of rats. When young it is easily domesticated, and valuable as a rat-catcher. It does not appear to have been seen in Arracan.—*Mason.*

(5970) PALANG POSH OR PALAMPORE. The former term is composed of two Persian words, literally "Bedcover." These are manufactured in the district of Cuddalore at Ponnary

also at Sydapett in the outskirts of Madras, but especially in the town of Masulipatam, the last always of a superior kind and in various sizes, 5½ to 6 cubits in breadth and 7 to 8 long and are sold from 6 Rupees to Rs. 15 according to size. The Cuddalore, Pannary and Sydapet fabrics are of ordinary quality and are sold at from Rupees 2 to 7 each.

(5971) PALAS GUM. Pulas goond or Dhak ke goond. Produce of Butea frondosa, in ruby red, transparent grains or irregular tears.

(5972) PALEMONIDÆ, a family or tribe of Macrurous Decapodous *Crustacea*. They belong to Milne-Edward's family of *Salicoques*, or Shrimps, and his tribe Palemonians The characters of this tribe are as follows:—Body laterally compressed, but the abdomen never sharp. Thorax large, carapace armed in front with a great sabre-like rostrum, nearly always dentated above. Antennæ placed as in the preceding tribe, but longer, and the first pair often with three terminal filaments. All the feet are slender, and the first two pairs are generally didactylous, whilst the last three pairs are never didactylous. The abdomen is of great size. (Milne-Edwards.) The genera are, *Guathophyllum*; *Hippolyte*; *Rhynchocinetes*, *Pandalus*; *Lysmata*; and *Palemon*.

(5973) *Rhynchocinetes*. (Edwards).

R. Typus. Front armed with three spines, of which the median, placed above the base of the rostrum, is followed by another median spine; rostrum very large, longer than the lamina of the external antennæ, armed above with two spines situated near the base, and with seven or eight dentilations situated at its extremity; its inferior border furnished with a score of very large teeth. Length about 2½ inches. It is a native of the Indian Ocean. (Milne-Edwards.)

(5974) *Palemon*. (Fabr.) THE PRAWN. Body compressed but little, and generally rounded above. M. Milne-Edwards remarks that the nervous system of the Palemons presents a much greater concentration than that of the Crawfishes (Ecrevisses); for all the thoracic ganglions are approximated, so that they nearly touch each other. The branchiæ, he observes, are eight in number on each side of the body. The species of this useful and delicious genus are numerous. M. Milne-Edwards records seventeen, besides the Indian *Palemon bivimanus* and *P. Coromandelinus* of Fabricius. Those of British coasts are well known to the epicure; and some of the species which are found in warm climates attain to a considerable size: such are the *P. Carcinus* of the Indian seas and the Ganges, which attains to nearly a foot in length, and the *P. Jamaicensis* of the Antilles, which is from 10 to 12 inches long. The prawns generally inhabit sandy bottoms near the coasts, but some are found at the mouths of rivers, and far up. They mostly boil red.

(5975) *Alpheadæ*. The shrimps comprised by M. Milne-Edwards under this tribe, are stouter in their forms than those of the preceding division, but they are not depressed as the Crangons are. [CRANGONIDÆ] The genera are *Atya*, *Ligmenocera*, *Alpheus*, *Pontonia*, *Autonomea*, *Caridina*, *Nika*, and *Athanas*.

(5976) *Alpheus* (Fabr.).—Carapace advanced above the eyes, forming above each of those organs a small vaulted buckler. They are found in the seas of warm climates. Some species are found in the Mediterranean, but the greater part in the seas of the Antilles or in the Indian Ocean.

5977) *Pontonia* (Latr.).—Carapace short and convex: the front with a short but robust and inflected rostrum; the eyes are cylindrical, projecting, and very moveable. M. Milne-Edwards divides the *Pontonia* into the following sections:—

P. macrophthalma, from Asiatic seas, where it was found by M. Dussumier.

(5978) *Stenopus* (Latreille). *Penœdæ of* Milne-Edwards: Body not compressed laterally, and teguments comparatively soft. Carapace terminated anteriorly by a small rostrum.

Stenopus hispidus; *Palemon hispidus*, Oliv., from the Indian Ocean.

(5979) *Acetes* (Milne-Edwards).—Analogous to *Sergestes* in its conformation, but placed at a distance from all the animals of the same order by the absence of the last two pairs of feet.—*A. Indicus*.—*Eng. Cyc.*

(5980) PALI.

Pali. TAM.	Palari, PORT.
Irambu. MAL.	

The Ceylon wood known in England by the name of Iron wood. It grows to about thirty feet in height, and twenty inches in diameter. It is very useful for stocks of anchors, piles for jetty heads, beams in store houses and places where strength is required; for such purposes it will be found useful and durable: it may be obtained in great quantities at a very moderate rate.—*Edye. Ceylon.*

(5981) PALINURUS, the name given by Fabricius to a genus of *Crustacea* which forms the tribe of Langoustiens in the system of M. Milne-Edwards, being the fourth of his family of Cuirassed Macrurians, and characterised by the existence of antennæ of the ordinary form and the absence of didactylous pincers. It is also regarded as the type of a family of the *Palinuridæ*. The *Palinuri*, or Sea-Crawfish, as they are popularly called, have the body nearly cylindrical. Their carapace is nearly straight from before backwards, very convex transversely, and presents about its anterior third part a deep transverse furrow, which is directed forward on each side and separates the stomachal from the cardial and branchial regions, the only ones which can be well distinguished.—*Eng. Cyc.*

(5982) PALINURUS FASCIATUS, Antennular ring armed above with two conical rather large teeth situated near its anterior border. Carapace armed with a small number of spines, and slightly granular, or only dotted on its posterior half; lateral tooth of the anterior border of the carapace small; no spines on the median line of the stomachal region; median tooth of the anterior border of the epistome very large. Length about a foot. It is a native of the Indian Ocean.—*Eng. Cyc.*

(5983) PALINURUS VULGARIS, the common Sea Craw-Fish, or Spiny Lobster; Langouste of the French. Length about 18 inches. Weight sometimes from 12 to 15 lbs. It inhabits the seas of Europe, and is common on the rocky coasts of Britain especially in the South, and on the like coasts of France, especially in the south and west.—*Eng. Cyc.*

(5984) PALMACEÆ, *Palms*, a natural order of Endogenous Plants, usually trees, with simple stems, inhabiting the warmer parts of the world and especially tropical countries. They constitute a most important order, on account of the many uses to which the species or their products are applied. They are nearly allied to the Liliaceous and Juncaceous or Rushy Plants of northern countries. Linnæus, who had scarcely any means of judging of the real structure of their fructification, and was therefore uncertain where to station them in his sexual system, placed them in an Appendix by themselves and called them the Princes of Vegetation. It has now however been ascertained that they chiefly belong to *Hexandria*, *Monœcia*, and *Diœcia*. In general they adhere to the soil by clusters of strong simple roots which not uncommonly form a hillock elevated above the surface of the ground. Their trunks are solid, harder on the outside than the centre, and are sometimes, as in the Cane Palms, coated by a layer of siliceous matter; they are usually quite simple, growing exclusively by a single terminal bud, called in the *Areca* its cabbage, and eaten as a delicacy when boiled; but in the *Hyphæne*, or Doom-Palm, they are regularly forked. In the majority of the order the stem is nearly cylindrical, but in some it is thickest at the base, and in others swollen in the middle; occasionally it is defended by strong hard spines, but is more frequently unarmed, and marked by rings which indicate the places whence the leaves fall off. The leaves, called fronds by Linnæus, are alternate, with a very hard epidermis and a distinct petiole, from the base of which a coarse network, called reticulum, sometimes separates next the trunk; they are usually either pinnated or fan-shaped, but are occasionally nearly split in two; their veins are parallel, the spaces between them plaited, and the whole size sometimes very great, as in the Fan-Palm, in which specimens have been seen as much as 18 or 20 feet in breadth. [CORYPHA.]

The flowers appear in panicled spikes from the inside of hard dry spathes, which are often boat-shaped, and although small, they are sometimes so extremely numerous that each panicle will weigh many pounds. They are generally hermaphrodite, but often monœcious, diœcious, or polygamous. The calyx and corolla consist each of three pieces, which are either distinct or more or less united. The stamens vary in number, from 3 to a large multiple of that number, and bear 2-celled linear anthers, which open along their inner face. The ovary consists of 3 carpels, which are sometimes distinct, sometimes consolidated, and occasionally in part abortive, so that the ovary is only 1-celled. The ovaries are almost always solitary, and erect in each cell, but sometimes two are present, which in that case stand side by side; they are orthotropous in some genera and anatropous in others. The styles are very short, the stigmas simple. The fruit varies extremely in its consistence and appearance. Sometimes it is 3-celled, often 1-celled; in such species as the Cocoa-Nut it is a kind of drupe covered by a coarse fibrous rind; in others it is a soft sweet eatable pericarp, as in the date; in others its surface is broken up into lozenge-shaped spaces, as in the *Sagus*, whose fruit looks as if covered with scale-armour. The seed is single, either solid or hollow, and consists principally of albumen of a fleshy, oily, horny, or cartilaginous texture, within which is lodged a very small cylindrical embryo at some part of the surface distant from the hilum. Palms appear to prefer a soil in some measure salt, although many species are inhabitants altogether of inland districts and even of high mountains. Their geographical limits appear to be within 36° N. lat. in America, 44° N. lat. in Europe, 34° N. lat. in Asia, and 38° S. lat. in the southern hemisphere; and according to Von Martius, their powers of migration are extremely small; none of them have been able to cross the ocean without the aid of man. Their favourite stations are said to be the banks of rivers and water-courses, and the sea-shore, some species scattered singly and others collected together into large forests. There is scarcely a species of this order in which some useful property is not found. The Cocoa-Nut [COCOS], the Date [PHŒNIX], and others are valued for their fruit; the Fan-Palm and many more for their foliage, whose hardness and durability render it an excellent material for thatching; the sweet juice of the Palmyra [BORASSUS] when fermented yields wine; the centre of the Sago-Palm abounds in nutritive starch; the trunk of the *Iriartea* or *Ceroxylon* exudes a valuable vegetable wax [CEROXYLON]; oil is expressed in abundance from the Oil-Palm; an astringent matter resembling dragon's blood is produced by *Calamus Draco*; many of the species contain within their leaves so hard a kind of fibrous mat-

ter, that it is employed instead of needles, or so tough that it is manufactured into cordage; and finally, their trunks are in some cases valued for their strength and used as timber, or for their elasticity, or their flexibility, as in the Cane-Palm.[CALAMUS.]—*Eng. Cyc.* Thus, the Palms, so conspicuous in tropical countries for their lofty pillar-like stems, surmounted by apparently inaccessible fruit or gigantic foliage, are no less remarkable for the many useful purposes they are calculated to fulfil. The fruit of some is edible, of others abounding in oil, the sap of a few forms a pleasant beverage, and may by evaporation yield sugar or be fermented into a spirit. The stems of some species are gorged with farinaceous matter, which may be separated as a starch-like powder or granulated into sago. The broad leaves, from their great size and hard surface, are useful for thatching the cottages of the poor, or for making umbrellas for the rich. The narrow-leaved kinds are plaited into mats and baskets, or smoothed so as to be fit for writing on; while the leaves of several, when in a young and tender state, are eaten, both raw and in a cooked state, and are hence called Cabbage Palms. Some abound in strong unyielding fibre, while others form wood which is applicable to all the purposes of timber. Hence, several are valuable articles of culture in the countries where they are indigenous, or where the soil and climate are suitable for their growth—as, for instance, the Date Palm in Arabia and Africa, the Oil Palm in the West of Africa, the Cocoa-nut in India and its Islands, together with the Betle-nut, Palmyra, and Talipat Palms; while the Sago, the Ejoo, and the Betle-nut Palms flourish in the moist warm climates of the Malayan Peninsula and of the Indian Archipelago. The Palms abound chiefly in the tropical parts of South America, as well as of the Old World; but a few species extend to rather high latitudes, as an Areca to lat. 38° S. in New Zealand, and a Sabal (Chamærops, *Auct.*) to lat. 40° N. in North America; while the Dwarf Palm, a native of the North of Africa, is now at home in the South of Europe. There even the Date Palm is grown in a few sheltered situations; though it is in the hot and dry soil of Arabia and Africa that it attains the greatest perfection, and furnishes a principal part of the diet of its inhabitants, as well as an article of commerce. *Phœnix sylvestris*, a variety or species of the same genus, is common in most parts of India. A Chamærops is found in Nepal, and one on the Khasya Hills, at elevations of from 5000 to 8000 feet; while *C. Ritchiana* is found in the Khybur Pass, and probably all along the mountainous range from Affghanistan to Sindh. But it is in far southern latitudes and in a different climate that the Cocoa and the Betle-nut Palms are objects of extensive culture; as well as the Sago Palms, of which the Ejoo or Gomuto of the Malays is one

(the *Arenga saccharifera* of botanists), abounding in sap, which can be used as palm wine or converted into sugar; yielding at all times strong and durable fibre. The older trees when cut down yield sago, as do *Sagus Rumphii* and *S. lævis*, especially abundant in and near Sumatra. The latter is remarkable among Palms for throwing up young plants around it in the same manner as the Plantain. Both kinds of Sago tree are strongly recommended for cultivation—the Arenga on low coasts near the sea, but the species of Sagus even on the edges of the marshes which abound in such situations. It is no doubt to some one of these Sago trees that Sir John Maundeville alludes, when he says: "In that land grow trees that bear meal, of which men make bread, white and of good savour; and it seemeth as it were of wheat, but it is not quite of such savour. And there are other trees that bear good and sweet honey; and others that bear poison.—And if you like to hear how the meal comes out of the trees, men hew the trees with an hatchet, all about the foot, till the bark be separated in many parts; and then comes out a thick liquor, which they receive in vessels, and dry it in the sun, and then carry it to a mill to grind, and it becomes fair and white meal; and the honey and the wine, and the poison, are drawn out of other trees in the same manner, and put in vessels to keep." ('The Book of Sir J. Maundeville," chap. xviii.) The leaves of many Palms are employed for thatching, for making chattahs or umbrellas, punkahs, and hats. The stems of *Licuala acutifida* afford the well-known walking sticks known by the name of "Penang Lawyers.' (Griffith) Thus, those of *Licuala peltata*, the *Chattah-pat* of Assam, are in universal demand in that valley. Scarcely a single ploughman, cow-keeper or cooly, but has his Jhapee or Chattah made of Chattah-pat (Jenkins). But the leaves of this Palm are coarser than those of another, the *Toka-pat* of the Assamese, which has been named in honour of the zealous Commissioner of Assam, *Livistona Jenkinsiana*, by the late Mr. Griffith. Col. Jenkins says that this species of Palm is an indispensable accompaniment of every native gentleman's house, but in some parts it is rare, and the trees are then of great value. The leaves are in universal use throughout Assam, for covering the tops of doolees (palkees), and the roofs of khel boats; also, for making the peculiar hats, or rather umbrella-hats (jhapees) of the Assamese. For all these purposes the leaves are admirably adapted, from their lightness, toughness and durability." To the above list of useful Indian Palms, we might easily add some, such as *Zalacca macrostachya*, used for making baskets and for tying Nipa leaves (p. 36), as well as mention the native names of others employed for many of the same purposes as the foregoing. The Chinese are said to make cables of Palm

leaves. The *Areca vestiariâ* is so called from clothing being made from its fibres, and *Rhapis cochinchinensis* is employed for thatching, &c. *Lodoicea Seychellarum* (the Palm yielding the formerly much famed "Cocos de Mer" or "Double Cocoa-nut") are formed into baskets and flowers —for a specimen of which, in the Mauritius collection, a Prize Medal was awarded at the Exhibition of 1851. The Palms prove the great value of these plants to the regions where they are indigenous —yielding flour and sugar milk and honey-like fluids, demulcent drinks and fiery spirit, fibre for cordage and for clothing, leaves for thatching and for platting, as well as wood for a variety of purposes. There is little doubt that some may yield the fibre which so abounds in their leaves, sufficient easily to be useful to the paper-maker.—*Royle, Fib. p.* Further information on the various palms of Eastern and Southern Asia, the Coco-nut palm, Palmirah, Corypha, Caryota urens, Arenga Saccharifera, will be found under these several heads. This natural order of plants is one of the largest, the most beautiful, as well as the most useful of the whole vegetable kingdom. They are almost exclusively plants of tropical countries. They belong, systematically speaking, to the Endogens or monocotyledons, the same great division which comprises the grasses, Sedges, Lilies, Orchids and Screw-pines and most of them attain the size and assume the aspect of trees. Palms having arrived at the proper age, flower every year until they die, or only once during the whole course of their existence, and have sometimes from 200,000, to 600,000 flowers on a single tree. The fruits are almost of every colour, and a single spathe of the Seje Palm of the Orinoco bears as many as 8 000 of them. The common cocoanut is one of the largest of the fruits and the double cocoanut of the Seychilles measures about four feet in circumference and probably surpasses all others in dimensions. There are not less than 1 00 known species of this useful plant. Palms are associated with the most sublime truths of Christianity, and in our every day life we speak of our "Palmy day" and "carrying of the palm," as happy and excellent times and seasons of rejoicing. Various products are largely made use of by the inhabitants of the countries in which they grow, and they are exported to peoples thousands of miles away, who employ them for many purposes, useful and economic. The sweeper of the crossings of London, holds in his hand a broom, the fibrous portion of which was cut by the wild Indians of Brazil from the stems of a palm: the gentleman who prides himself on his Penang Lawyer, is but carrying a young plant of the Licuala acutifida. The knob of the ladies parasol, is formed from a Coquilla-nut, turned into that shape. The chip hats, so extensively worn on fine summer days, are made of the leaves of a Cuban palm (*Thrinax argentea*). Heaps of dates are to be seen in all the shops of Europe which were gathered by the Bedouin Arabs, or on the borders of the great desert of Sahara; and cocoanuts grown on the shores of the Indian Ocean, in the myriads of islands which form its Archipelago, or on the shores of the Carribean sea, are sold in every city of the colder regions of the world, where they are ever beheld with unabated curiosity. The cordage and rigging of the ships, and the thick mattings used on stair cases in England, spun and woven, are from the husk of the cocoanut, and many articles of furniture are made from the woods of Palms. Toys and ornaments are made from the kernels of the vegetable Ivory palm. The stearic candles so well known are composed of the fatty substance extracted from the oil palm and the cocoanut. The sago which ministers so powerfully to the recovery of the sick, and which is seen in such varied guise on our tables, is the pith of palms that flourish in many tropical regions, the famous Betel nut dentifrice formed of the charcoal of that nut, colored with dragons blood, is the produce of two palms, and the toilet soaps of Europe are made from palm oils. Every where we meet with numerous products of Palms, either in a raw state, or turned by the ingenuity of man to some useful purpose; and millions of people who never saw a palm are benefitted by the products of these useful trees But if this be felt in remote regions of the cold north, in the tropical regions of Asia, Africa, America and Australia, where these elegant members of the vegetable kingdom flourish in all their native splendour, the inhabitants derive from them many of the necessaries, comforts, and luxuries of life, and come more or less in contact with them in almost every action of daily life. In household economy, parts of them are formed into spoons, and cups, and ladles and lamps, and hats and clothes, and combs, and hammocks, and bowstrings, and fishing lines, and fish-hooks. The light rafters of their houses are obtained from the straight cylindrical trunks of the Jara Palm (Leopoldinia pulchra), the date or palmyra tree. The roof is thatched with the leaves of palms. In one region, the door of the house is made of the split stems of the Pashiuba Palm, (Iriartea exorhiza), and in another the thickly matted leaves of the cocoanut and palmyra serve as a door for the gardens and parterres. The harpoon for catching the cow fish, is formed of the blackwood of the Pashiuba barriguda (Iriartea ventricosa.) The people eat the fruits the produce of many of this tribe of trees, and in the palm-wine and Arracks from the various plants, they enjoy palatable refreshing and stimulating drinks.—*Seemann.*

The *Chamærops Khasiana* The fan-palm, ("Pakha," Khas.), grows on the cliffs near Mamloo on the Khasia hills: it may be seen on looking over the edge of the plateau, its long

curved trunk rising out of the naked rocks, but its site is generally inaccessible : while near it grows the *Saxifragis ciliaris* of English Gardens, a common plant in the north-west Himalaya, but extremely scarce in Sikkim and the Khasia mountains. This species of Chamærops is very closely allied to, if not identical with *P. Martiana* of Nepal, which ascends to 8000 feet in the western Himalaya, where it is annually covered with snow : it is not found in Sikkim, but an allied species occurs in Affghanistan, called P. Ritcheana. The dwarf palm of Southern Europe is a fourth species.—*Hooker, Him. Journ, Vol.* II. *p.* 280. There are upwards of twenty kinds of Palm in the Khasia district, including *Chamærops*, three species of *Areca*, two of *Wallichia, Arenga, Caryota*, three of *Phœnix, Plectocomia, Licuala*, and many species of Calamus. Besides these there are several kinds of *Pandanus*, and the *Cycas pectinata*—*Hooker, Him. Jour. Vol.* II. *p.* 267. Palms of the Khassia hills amount to fourteen, of which the *Chamærops* and *Arenga* are the only genera not found in Sikkim.—*p.* 281.

(5985) PALM. The term applied in Southern India to the bars of iron, manufactured from Cutties.

(5986) PALM BOOKS. The books and separate leaves employed for writing on, in Asia, are made from the leaves of the Taliput Tree *Corypha Umbraculifera*, also from the Tara, Taleet, or Tallier of the Bengalese *C. Taliera*, Roxb. All the Burman books are made of the leaf of a species of corypha, but the orders that are issued from the Burmese courts are written on strips of palmyra palm-leaf.—*Mason.* Those used in Southern India for the accounts of shop-keepers, the orders of Collectors, and village accounts are made of the leaf of the palmyra.

(5987) PALMA CHRISTI. Castor Oil Plant.

Jarak Malay, & Jav.	Tangan-tangan, Philippine.
Kaliki Sunda & Mad :	

(5988) PALM OIL.

Huile de palme, Huile de Senegal. Fr.	Olio di palma, It.
Palmol, Ger.	Aceite de palma. Sp.

A fatty substance, obtained from the fruit of several species of palms, but chiefly from that of the *Elais Guineensis*, growing on the Western Coast of Africa. It has the consistence of butter, a yellowish colour, and scarcely any particular taste ; and becomes rancid on being kept for any length of time. It is chiefly used in England for the manufacture of toilet soap, pomade-perfumery ; also in medicine and surgery. The African Palm Oil of Commerce, so much imported into England for the Manufacture of Prices' Patent Stearic Candles, is the produce of this Elais Guineensis ; Linn., a native of Africa. Another species, E. melanococca, Gaertn : is a native of America : both species might be profitably introduced into India.—*Seeman.*

(5989) PALM WINE. Toddy.

Tuwak, Malay & Jav.	Nera, Malay.
Taree Sendee & Narellie, Hind.	Kulloo, Tam. & Telegoo.

The fermented juice of several species of palms.

(5990) PALM-WOODS. Two or three varieties only, of the four or five hundred which are said to exist, are imported into Great Britain from the East and West Indies. They are known in England by the names, palm, palmetto, palmyra, and nutmeg, leopard, and porcupine wood, &c. from their fancied resemblances, as when they are cut horizontally, they exhibit dots like the spice, and when obliquely, the markings assimilate to the quills of the porcupine. The trunks of the palms are not considered by physiological botanists to be true wood, they all grow from within, and are always soft and spongy in the centre, but are gradually harder towards the outside : they do not possess the medullary rays of the proper woods, but only the vertical fibres, which are held together by a much softer substance like pith or cement, so that the horizontal section is always dotted, by which they may be readily distinguished from all true woods. The colours and hardness of the two parts differ very materially, and through the kindness of Sir James Sutherland, and Colonel Sykes, are given the distinctive names of the following three :—

The *Areca Catechu*, or betle-nut palm, is remarkably perpendicular, it grows to the height of about 30 feet, and rarely exceeds 4 or 5 in diameter, it bears a small tuft of leaves, and the fruit is in clusters like grapes. The betle-nut is chewed along with quick lime and the leaf of the Piper Betle, in the manner of tobacco. The general colour of the wood is a light yellow brown, the fibres are large, hard, and only a few shades darker than the cementitious portions.

The *Cocos nucifera*, or cocoa-nut palm, flourishes the best in sandy spots near the sea beach, and sometimes grows to 90 feet in height and 3 feet in diameter, but is generally less ; it is rarely quite straight or perpendicular, and has broad pendent leaves from 12 to 14 feet long, in the midst of which is a sort of cabbage, which, as well as the fruit, the cocoa-nut, is eaten : the husk of the nut supplies the material for coir rope and matting. No part of this interesting tree is without its grateful service to the native of the Tropic, the leaves are used for making baskets, mats, and the covering of his dwelling ; he also obtains from this tree, oil, sugar, palm-wine and arrack, and although the upper part of the trunk is soft and stringy, the lower supplies

an useful wood, the fibres of which are of chesnut brown, and several shades darker than the intermediate substance; the wood is employed for joists, troughs for water, and many purposes of general carpentery. The Asiatic Society has specimens marked, male, 1st; and; 3rd; 4th sorts, and the same number of female varieties: no material distinction is observable between them.

The *Nirpeire palm*, Caryota urens, is much darker than either of the preceding kinds; the fibres are nearly black and quite straight, and the cement is of a dark brown, but in other varieties with these black fibres, the softer part is very light-coloured and so friable that it may be picked out with the fingers; Colonel G. A. Lloyd has mentioned that at the Isthmus of Darien, they use the fibres of some of the palms as nails for Joinery work.

Palmyra wood, or that of Borassus flabelliformis, says Mr. Laird, is largely imported into Madras and Pondicherry, from the Jaffna district at the northern part of Ceylon, for the construction of flat roofs, the joists of which consist of two slabs, the third or fourth part of the tree, bolted together by their flat sides so as to constitute elliptical rafters. They are covered first with flat tiles, and then with a white concrete called Chunam, consisting of shell lime, yolks of eggs, and Jaggree (Sugar), beaten together with water in which the husks of cocoa-nuts have been steeped.

The *prickly pole* (Cocos Guianensis) of Jamaica. &c., a palm growing 40 feet high, and of small diameter, is said to be very elastic, and fit for bows and rammers.—*Capt. Symonds.*

The *palm woods* are sparingly employed in England for cabinet and marquetry work and sometimes for billiard cues which are considered to stand remarkably well; they are also turned into snuff boxes, &c. The smaller kinds are imported under the names of Partridge canes (called also Chinese or fishing canes,) Penang canes from the island of that name, together with some other small palms which are used for walking sticks, the roots serving to form the knobs or handles. The knobs of these sticks exhibit irregular dots something like the scales of snakes, these arise from the small roots proceeding from the principal stem; which latter shows dotted fibres at each end of the stick, and streaks along the side of the same. The twisted palm sticks, are the central stems or midribs of the date palm; they are twisted when green, and stretched with heavy weights until they are thoroughly dry: they are imported from the Neapolitan coast but are considered to be produced in Egypt. The shells of the cocoa-nut and coquilla-nut, and the kernels of the areca or betle-nut, and those of the corosos or Ivory-nut, have likewise their uses in English workshops.—*Tredgold.*

(5991) PALMINE may be prepared from the commonest castor oil in the country, and can possibly be obtained from other oils also, by treating them with nitric or nitrous acids. A process is given in Braude's Manual of Chemistry Vol. II p. 1257, and supposed to be the substance which has been lately patented for the use of railway carriages in this country, and whether as regards its origin, the facility of making it, the abundance of the castor oil plant in India, its consistence and cheapness, it well deserves attention. The Nitric or Nitrous acid, *Shore ka tezab* is usually obtained by distilling nitre, *Shora*; HIND, with Sulphuric acid, *Gundhuc ka tezab*; of which two materials various proportions are employed When Nitrous or Nitric acid is made to act upon castor oil, it is converted into a solid wax like substance, and a similar, though much more rapid, result takes place when olive oil the *Zeitoon ka tel* of the bazars, is similarly treated with Nitrate of Mercury; but it deserves notice that castor oil is the only one of the drying oils which is susceptible of this species of solidification. On adding nitrous acid to castor oil a yellow liquid is at first formed, and the time required for its solidification varies with the quantity of acid employed; when about a twentieth part of acid is used, it solidifies in seven or eight hours, and this or somewhat less, is the best proportion. If too much acid be used, a third part, for instance, or a half, the temperature rises to 130° or 140°; effervescence ensues and the oil becomes opaque, and instead of indurating remains viscid. Palmine thus obtained is yellow, but when purified by solution in boiling alcohol, it is white, of a waxy fracture and requires a temperature of about 150, for its fusion. When this is kept for some months it occasionally acquires a resinous appearance and presents an almost vitreous fracture. It has appeared to me that a large and profitable trade might be had in Palmine made from the cheap oils of Southern Asia, the difficulty of transporting which is well known. The same effect is produced on this oil and on Olive oil by adding the Nitrate of Mercury.—*Author.*

(5992) PALMYRA. BORASSUS FLABELLIFORMIS.

Tar kajhar, HIND | Tatty Chettoo, TEL.
Panna marum, TAM.

This tree is very abundant, especially in sandy tracts near the sea. It is used chiefly for rafters, joists and reapers, when of good age, the timber is very valuable for this purpose, the trunk is split into 4 for rafters, into 8 for reapers, these are dressed with an adze. Those of Jaffna Palmyrahs are famous, and were largely imported in former times. From the structure of the fibres, it splits easily in the direction of its length, but supports a greater cross strain than any other wood: iron nails, however, rust rapidly in it. The fruit and the fusiform roots of the young trees (in the Northern Circars) are used

as an article of food by the poorer classes. The leaves are used for thatching and coarse fibre. Jaggery and Toddy are extracted from the Tree, the former is extensively used in the manufacture of Sugar in Vizianagrum and Rajahmundry. Very neat baskets of Palmyrah leaf are exhibited from Tinnevelly.—*M. E. J. R.* Some clean but brittle fibres were exhibited at the Madras Exhibition of 1855, by the Tinnevelly, Madura and Travancore local committees and well twisted rope accompanies most of the samples, but the material is said to be stiff, brittle, and liable to rot when wet. This substance did not appear to have undergone any preparation, and it contained so much woody fibre that it is questionable whether it would ever be suited for manufacturing purposes. Its chief uses are for securing thatch and tying bamboos, in building native huts. The dried leaves of this plant are used for writing upon with an iron style, also in thatching, making fans, and light baskets for irrigation. The Palmira tree of Europeans (*Borassus flabelliformis*), and the *Tar* of the natives of India, is to be seen in almost all parts of India, and occasionally as far as 30° N. lat. It is stated by Dr. Roxburgh to be next to *Caryota urens*, the largest Palm on the Madras coast, and that it seems to thrive equally well in all soils and situations. The seeds, when young are eaten by the natives, being jelly-like and palatable. The tree, during the first part of the season, yields a pretty large quantity of toddy (palm wine). This is either drank fresh drawn from the tree, or boiled down into a coarse kind of rob called jaggery, or it is fermented for distillation. The wood, near the circumference of old trees, is very hard, black, heavy, and durable. By the natives the leaves are universally used for writing upon with an iron style. They are also employed for thatching houses, for making small baskets, mats, &c., and some also formed into large fans, called visshries, Tam: The fibres of the leaves (*Palmyra nar*) are employed on the Madras side for making twine and small rope. They are about two feet in length, strong, wiry, and not unlike those of the Esparto of Spain. Near the base of the leaves there is also found a fine down, which is used for straining liquids through, and also for stopping bleeding from wounds.—*Royle, Fib. Plants, p.* 93. The palms undoubtedly constitute the noblest tribe of plants in the whole vegetable kingdom; and there is a large number of species indigenous, and cultivated in the Tenasserim Provinces. Excepting the areca and cocoanut, the palmyrah palm, is more generally diffused than any other.—*Mason.*

(5993) PALOO. A hard, fine, close grained, heavy Ceylon wood: heart-wood deep red brown, recent layers reddish yellow; its compact, even structure, indicates that it is admirably adapted for turning work.—*Exhibition of* 1851.

(5994) PALUDINIDÆ a family of Prosobranchiate Gasteropodous *Mollusca*. The species are all inhabitants of the fresh water. They embrace Lamarck's family of Peristomians. The genera included in it are *Paludina, Valvata, Ampullaria, Amphibola*, and *Bithinia*. Through *Ampullaria* the family is allied with *Neritidæ*.

Paludina (Lam). – This form is widely spread. Species have been found in Europe, Asia, Africa, and America. The European species are the inhabitants of temperate climates. The number of recent species of *Paludinæ* given by Woodward is 60 and of fossil species 50.

Ampullaria (Lamarck).—*Eng. Cyc.*

(5995) PAN. PIPER BETEL. Betel Pepper. This is cultivated in spots by itself; it requires much water and care, and is too well known to need any further description here. The leaves are eaten raw.—*Riddell.*

(5996) PANAX, (intended to be formed from πᾶν, all, and ἄκος, a remedy), a genus of Plants belonging to the natural order *Araliaceæ*. The flowers are polygamous, the calyx obsolete and 5-toothed. It has 4 petals, 5 stamens inserted with the petals under the edge of the disc, and alternate with them. The fruit is succulent, compressed, orbicular, from 2- to 3-celled; the cells leathery and 1-seeded. The species are herbs and shrubs and trees, having the leaves and inflorescence variable.—*Eng Cyc.*

(5997) PANAX FRAGRANS.

Gooti-soona, HIND.

A shrub, with fragrant flowers of a green color, a native of Nepal.—*Riddell.*

(5998) PANAX FRUTICOSUM is used in China and Cochin-China as a febrifuge, and as an astringent tonic. It has a shrubby unarmed stem, pinnately decompound leaves; petiolate oval oblong leaflets, coarsely and dentately serrated, the ultimate ones deeply trifid, the panicle corymbose, with the branches umbelliferous at the apex. It is a native of the islands of Ternate, Java, and Amboyna. (Lindley, *Flora Medica*; Burnett, *Outlines of Botany*.—*Eng. Cyc.* Commonly grown in Indian gardens, easily propagated from cuttings.—*Riddell.*

(5999) PANAX OBTUSUM. A shrub, like the former, but not so commonly cultivated in gardens, the roots of all are said to possess medicinal qualities, and are much esteemed by the Chinese for their beneficial influence on the nerves.—*Riddell.*

(6000) PANAX PSEUDO-GINSENG. Dr. Wallich has discovered in Nipal a species of Panax closely allied to P. quinquefolius and of which he has published an account in the 4th vol. of the Transactions of the Medical and Physical Society of Calcutta, and in his *Plantæ Asiat Rarior*. vol. ii. p. 30, t. 137. Dr. Wallich names his species *Panax Pseudo-ginseng.*

(6001) PANAX QUINQUEFOLIUS GINSENG. *Syn.* AURELIANA CANADENSIS.

The roots are about the thickness of the finger, like those of parsley, of a whitish yellow colour externally, white within, two to three inches long, wrinkled, or with rings, often divided into two branches, rarely into three or four, and these presenting a slight likeness to the human form, whence the Chinese name is derived; the parenchyme is formed of a horny and compact tissue, displaying some resinous points. Above the neck is a knotty twisted tissue formed by the remains of the old stalks. The odour is sweet, and weakly aromatic, the taste saccharine, somewhat like that of liquorice, subsequently bitter, and rather aromatic. The root of an Umbelliferous plant, the *Sium Ninsi*, is often mixed in the druggist's shops, or mistaken otherwise for the ginseng; the essential difference consists in the ginseng having the neck covered with fibrous threads, the remnants of the cortical part of the stalk. The root abounds in gum and starch, and has a little resin and essential oil. The plant is about a foot high, with glabrous, straight, simple stalks, terminating in three leaves, each composed of six uneven leaflets, a little pedicelled, oval, lanceolate, acute, and toothed at the edge. The flowers are borne on a central peduncle, and disposed in an umbel. The berries are kidney-shaped, red, compressed, crowned with the calyx and styles, and containing two semicircular seeds The ginseng root is one of the substances which, without any obvious cause, has attained the highest celebrity and esteem among mankind for its alleged medicinal virtues. The Dutch were the first nation who made it known in Europe, where they brought it from Japan in 1640 The Japanese themselves were indebted for it to China. The plant grows in the great forests of Tartary between the 39th and 47th degrees of north latitude; it is also found in abundance in Virginia and Canada, a circumstance which has rendered the roots so common that they are now cheap in China, where they once sold for their weight in gold. It would be superfluous to follow M. Fe[illegible] and other authorities in the details they afford regarding the cultivation and gathering of the ginseng. The Chinese in their hyperbolical phraseology name the root, "the pure spirit of the earth," the "recipe of immortality," the "queen of plants," &c., and in short regard it as a panacea for all the diseases to which they are liable.—*O'Shaughnessy, p.* 373-74.

Five-leaved panax or *Ginseng*, has a fusiform root more or less branched, of a whitish colour, and terminating in fibres. The stem is smooth, round, and green, often with a tinge of red, divided at the top into three petioles with a flower-stalk in their centre. The petioles are round, smooth, and swelling at their base. The leaves ternate, quinate, or septenate. The berries are kidney shaped, of a bright red colour, and contain 2 semicircular seeds. The flowers are of a yellowish colour. It is a native of Chinese Tartary and North America. In China, it has been considered an invaluable drug from time immemorial. In 1709 the Emperor of China commissioned 10,000 Tartars to go in quest of as much of this root as they could find; each one was to give two pounds of the best of it to the emperor, and to sell the rest for its own weight in fine silver. The roots enter into the composition of every Chinese medicine. It is reckoned a stimulant and restorative, and both rich and poor consider it a remedy for every disease. By Europeans and Americans however it is comparatively disregarded, and looked upon as a mere succulent, similar in its qualities to liquorice; hence the question arises, is the Chinese plant the same as the North American? For we cannot regard all that the Chinese say and practise as merely imaginary. The common name of the plant, Gen-seng, Jin-chen, or Nindsin, signifies 'wonder of the world,' or the 'dose for immortality;' and the Chinese firmly believe that its powers are almost miraculous.—*Eng. Cyc.* [GINSENG.]

(6002) PANDA, one of the names of the genus *Ailurus* (F. Cuv.), an animal belonging to the class *Mammalia* and the order *Carnivora*.

A. fulgens (F. Cuvier) is the only species of the genus. It was first described by General Hardwicke, who states that its haunts are about rivers and mountain-torrents. It lives much in trees, and feeds on birds and the smaller quadrupeds, and is frequently discovered by its loud cry or call resembling the word Wha, often repeating the same. Hence is derived one of the local names by which it is known. It is also called the Caitwa. It is found in the Himalaya chain of hills between Nepaul and the Snowy Mountains (Hardwicke, 'Linn. Trans.' vol. xv.). It is in Mr. Hodgson's Catalogue of the Animals observed in Nepaul ('Zool. Proc., 1834). Cuvier declares the *Ailurus* to be one of the most beautiful of quadrupeds. He places *Ailurus* among the Bears, between *Procyon* (Raccoon) and the Benturongs (*Ictides*) J. F. Fischer arranges it between *Gulo* (Glutton) and *Arctictis* (F. Cuv., *Paradoxurus* and *Ictides* of F. Cuv. and Valenciennes) —*Eng. Cyc.*

(6003) PANDAN, MALAY: SCREWPINE.

(6004) PANDANACEÆ, SCREW-PINES, a natural order of Endogenous Plants. The species are arborescent or bushy plants, with long rigid sword-shaped leaves, resembling those of the pine apple, usually arranged in a manner so obviously spiral that they are commonly called Screw-Pines. In a natural arrangement they are classed with Endogens, among which they are, more especially in the genus *Pandanus*, remarkable for their stems forking repeatedly. Their flowers have the sexes separate, and quite covering the spadix on which they grow. The male

flowers consist of single stamens with 2-celled anthers; the females of naked 1-celled ovaries, with solitary ascending or numerous parietal ovules. The fruit consists of a mass of ovaries collected into a tuberculated head, and either dry and fibrous or fleshy and succulent. These plants chiefly abound in the Mascaren Islands and in the Indian Archipelago, of which they form a conspicuous feature. The species of *Pandanus*, Vaquois, or Screw-Pine, are readily known by their spiral leaves, dichotomous habit, and the long roots emitted by the sides of their trunk for the purpose of holding it down in the loose sand among which they grow, in order to assist in which each root is furnished with a partial exfoliation of the end, which, in the form of a cup, adheres to the root, for the purpose, as is supposed, of holding water during the period that the root is passing through the dry air. The genus *Freycinetia*, on the contrary, is composed of plants with long scrambling or rooting stems, not branching like *Pandanus*, indeed seldom becoming what can be called a tree; and, when in flower, adorned with gaily coloured spathes from which the young inflorescence protrudes. Some of the species yield seeds which are edible. The order contains 7 genera and 74 species.—*Eng. Cyc.* The Screw Pines, are remarkable for their gigantic Bromelia-like leaves, arranged in a spiral manner. Though abounding most in Mauritius and Bourbon, species are also found in the southern parts of India, as well as in the Straits and Burmah." The leaves are composed of tough longitudinal fibres, white and glossy, which enable them to be employed for covering huts, making matting, as well as for cordage, in the South Sea Islands; and in Mauritius for making sacks for coffee, sugar, and grain." ('Himal. Bot.' p. 408.) The species which is best known in India is the *Keora* or *Ketgee*, the Kaldera bush of the Madras Peninsula, called *Pandanus odoratissimus* by botanists, on account of the exquisite perfume of its flowers. Dr. Roxburgh ('Fl. Indica,' iii, p. 741) has, under this plant, mentioned the uses to which the species most common in the Mauritius is applied; which, as well as some of the other species, is known there by the name Vacoa or Baquois. It appears to be the *Pandanus sativus* of Du Petit Thouars, but which Mr. Henley mentions as *P. Vacoa*. He having observed the valuable uses to which the plant was applied in the Mauritius, recommended its introduction into India; in some of the dry southern parts of which, it would, no doubt, though slow of growth, be a valuable acquisition, from the facility with which good sacking may be manufactured from its leaves. Mr. Henley describes this most useful Vacoa of the Mauritius to grow to the height of thirty feet, when permitted to do so; but in general, the cropping of the leaves, which commence in the third year, keeps the plant down to the height of from six to ten feet. The plant is remarkable for the aerial leafless roots which it sends down as supports for its stem, and which are of so fibrous a nature as to be employed for making paint brushes for common purposes. The leaves are cut every second year, beginning when the plant is three years old, and each plant yields enough for two large bags. The preparation must begin with the leaves immediately they are removed from the trees, and consists, first, in splitting the leaves into fillets, which are from three fourths to one inch broad at the base, but they taper to a point, and are from three to four feet in length. One of them will support the weight of a bag of sugar, or about 104 lb., without breaking. Mr. Henley states that the leaves of the other species with which he is acquainted are comparatively weak. ('Jour. Agric. Soc. of India,' 1843, p. 92.)—*Royle, Fib. pl. p.* 35.

(6905) PANDANUS, a genus of Plants, the type of the natural order *Pandanaceæ*. This name is derived from the Malay Pandang, and that of a genus of Plants, from which the natural family of *Pandanaceæ*, or Screw-Pine tribe, has derived its name, being so named from their leaves, which resemble those of the pine-apple, and are inserted spirally along the stem. The species are found in the islands of the tropical ocean, in those of Mauritius and Bourbon, as well as in the southern parts of India. One species, *P. odoratissimus*, being highly fragrant, is much esteemed in all Asiatic countries, either where it will grow or where its essence is known. It is constantly referred to by the Sanscrit poets, as may be seen in Wilson's 'Hindu Theatre,' by the name Ketaka, and as the Keora and Ketgee of the Hindoos. The Arabs call it Kazee, and Avicenna describes it under the name of Armak. Oil impregnated with the odour of its flowers and the distilled water are highly esteemed both for their odour and their medicinal use as stimulants. Dr. Roxburgh states that it is the tender white leaves of the flowers, chiefly those of the male, which yield the very delightful fragrance for which this plant is so celebrated. This species is common in the peninsula of India, where it is called Caldera Bush; in Mauritius it, as well as other species, is known as the Vaquois Plant; in Otaheite, a species is called the Wharra Tree, being in all highly esteemed for its odour, as well as for the useful purposes to which it may be applied. The lower pulpy part of the drupes is sometimes eaten, as is also the terminal bud, like that of the cabbage-palm, and likewise the tender white base of the leaves, either raw or boiled, during times of scarcity. It forms an excellent hedge, but occupies too much space. The roots are composed of tough fibres, which are used by basket-makers to tie their work, and are soft enough to be employed as corks. The leaves are composed of tough longitudinal

fibres, white and glossy, a quality which adapts them for covering huts, making matting, as well as for cordage in the South Sea Islands, and in Mauritius for making sacks for their coffee, sugar, and grain.—*Eng. Cyc.*

(6006) PANDANUS. HIGHLAND SCREW-PINE. Smaller and finer mats in common use are fabricated from the leaves of this species of screw-pine, that grows, in Tenasserim, on the highlands above tide-waters.—*Mason.*

(6007) PANDANUS FURCATUS. LOWLAND SCREW PINE. The large coarse mats in universal use in Tenasserim, are made from the leaf of a species of screw-pine, that grows abundantly on the lowlands near tide-waters.—*Mason.*

(6008) PANDANUS ODORATISSIMUS, CALDERA BUSH, Lin.

Talay ella, TAM.	Keteka, SANS.
Kewoore Ka Paut, DUK.	Keora, HIND.
Moghenakoo, TEL.	Kea kaida, BENG.
Kaida, HORT. MAL.	Kildaro, RHEED.

Its Flowers.

Talum poo, TAM.	Mogili poo, TEL.
Keoore Ka pool, DUK.	Katuca, SANS.

Magulick is the Telinga name of the male plant and Goz doogoo that of the female. Kaldera is the name they are known by amongst Europeans on the coast of Coromandel. It is a native of all the warmer parts of Asia: all soils and situations seem to suit it equally well; it flowers chiefly during the rainy season. This plant is much employed to make hedges, for which it answers well, but requires too much room. It grows readily from branches which renders it rare to find the full grown ripe fruit. The lower yellow pulpy part of the drupes is sometimes eaten by the natives during times of scarcity and famine; the tender white base of the leaves is also eaten raw or boiled, during the same melancholy periods. The fusiform roots already mentioned are composed of tough fibres which basket makers split and use to tie their work with, they are also so soft and spongy as to serve the natives for corks. The leaves are composed of longitudinal, tough, useful fibres like those of the Pine Apple. This plant is of extensive use in most parts of the island of Mauritius for its leaves, which are employed for the purpose of [illegible]kage bags for the transportation of Coffee, Sugar and grain from one place to another and for exportation. The preparation of the leaves for working into matting is simple and short: as soon as gathered, the spines or their edges and dorsal nerve are stripped off, and the leaf divided into slips of the breadth proper for the use they are required for: this operation is performed with the blade of a common straight knife, they are then laid in the sun for a few hours to dry when required for working into mats, the slips are passed under the blade of a knife applied with a moderate pressure to remove all asperities on their surface which gives them a polish and makes them plain, and more convenient to the hands—*Rox.* The Natives are fond of the scent of the flower which they place among their cloths. I was assured in the District of Ganjam, that the flowers are frequently tenanted by a small and very venomous Snake.—*Rohde M.S.S.* This plant grows abundantly in Travancore along the backwaters and canals, the fibres are extensively used, being good and strong.—*M.E. of* 1857. With the Leaves of the caldera bush, the Natives of lower India (like the inhabitants of the Friendly islands) make a fine kind of mat to sleep on, which they stain yellow and red with Cassia leaves and Vattiuga cuttay. They are also used to make the common kind of umbrellas, called by the Tamools Talay elley kedri. Dr. Roxburgh, in his "Coromandel plants," tells us that the yellow, pulpy part of the drupe of this plant is sometimes eaten by the Indians, in times of scarcity. He adds, that the fusiform roots are composed of tough fibres, which basket makers use to tie their work with. They are, at the same time so soft and spungy as to be employed as corks.—*Ain's Mat. Med. page* 145. It is in mats of these leaves, that the fine furnitures of Madras are packed.—*Nobis.* The male flowers of the fragrant pandanus or screwpine, are exceedingly fragrant, and great favourites with the Burmese. The palm-like shrub that bears them, dropping roots from its branches, like the banyan, is a very curious plant, and not inelegant.—*Mason.* This very fragrant flower which is of a pale yellow colour is offered up at the shrines of Mariama (Mariatale) and Vishnoo, but is supposed not to be acceptable to Sheva.—*Ains. Mat. Med. page* 159.

(6009) PANDANUS SAIL-LEAF. On many of the Burmese boats, sails are seen made of large narrow leaves, sewed together. They are the leaves of a species of screw-pine that has a trunk like a palm, which is very abundant and usually grows near the sea. The fruit is used by the Karens to hackle their thread.—*Mason.*

(6010) PANEOLA PLUM. Flacourtia Sapida.

(6011) PANDION. [FALCONIDÆ.]

(6012) PANDORA. [PYLORIDÆ.]

(6013) PANGIACEÆ. *Pangiads*, a natural order of Diclinous Exogenous Plants. This order embraces three genera, the species of which are trees with alternate stalked entire leaves, polypetalous axillary monœcious flowers, with scales in the throat of those bearing pistils. The stamens are five, the seeds large and oily. Dr. Lindley says, "What the distinction is between these plants and Papayads, except that the last are monopetalous, and have no faucial scales in the ♀ flowers, it is hard to say." The species are found in the hotter parts of India. They are all poisonous. The natives of India employ extensively in medicine the seeds of *Gynocardia*

odorata, which are known by the name of Chaulmoogra and Petarkura. The genus *Hydnocarpus*, formerly referred to *Flacourtiaceæ*, belongs to this order. [FLACOURTIACEÆ] (Lindley, *Vegetable Kingdom.*)

(6014) PANGOLINS, a name in common use to designate the Scaly Ant-Eaters, said to be derived from the word Pangoeling which signifies in the Javanese language, according to Seba, an animal which rolls itself into the form of a ball. The Bengalese name is Badjarkita, or 'reptile of stone.' These animals form the genus *Manis* of Linnæus. The Pangolins are toothless, and furnished with a very extensible tongue; but their tegumentary covering is very different, for their body, limbs, and tail are clad in a panoply consisting of great trenchant scales overlapping each other like tiles, so as to form a sort of scale armour when the animal is on its feet. When it is vigorously attacked, and often on the first approach of danger, it rolls itself up in the shape of a ball; and then the trenchant scales are said to be erected, and offer their sharp edges to the enemy.

(6015) *Manis* has the following characters: — Lower jaw very small; tongue very extensible. Body and tail entirely covered above with large triangular trenchant scales disposed quincuncially, and overlapping each other like tiles. Toes five, armed with robust claws. Body endowed with the faculty of rolling itself up more or less into the form of a ball, Dental Formula, 0. The Pangolins,are slow in motion, and live on worms and insects, especially termites and nuts, which they seize by means of their extensible and glutinous tongue.

(6016) *Manis pentadactyla* (*M. brachyura* of Erxleben and probably the Phattage of Ælian, xvi. 6), Indian, Broad-Tailed, or Short-Tailed Manis. It has the head small, pointed, and conic; muzzle elongated and narrow. Body rather stout. Tail short and very broad at its base. Dorsal scales disposed in longitudinal rows to the number of eleven; under part of the body, head, and feet naked; some long, fair-coloured hairs spring from under the scales. Middle claw of the fore feet far exceeding the others in its proportions. It is a native of the East Indies, coast of Tranquebar, &c. It feeds much on termites, or white ants, for the destruction of whose conicale nests the great middle claw is admirably adapted. Thunberg states that it is found much in Ceylon, especially near Negumbo. The Dutch call it the Negumbo Devil, and the Cingalese, Caballe. Its flesh was given to the sick to eat by way of remedy. Thunberg further informs us that the inhabitants have a method of making a hole in its skin with a knife, and thus of guiding and governing the animal at their pleasure, the point of the knife, which is kept in the hole, goading and irritating him. The cruelty of this proceeding does not however seem to have struck the traveller. The Land-Carp is also an Asiatic name for this species. It is the Kuwlee Manjar, or Tiled Cat, of the Mahrattas, according to Colonel Sykes, who notices it as very common in Dukhun (Deccan), and living on white ants. Mr. Hodgson, in his catalogue of the quadrupeds of Nepaul, mentions a new species of *Manis* allied to *M. Javanica* (Desm.), as being of frequent occurrence in the hills of the lower region, and in the mountains of the central tract. ('Zool. Proc.,' 1830, 1831, and 1834.)—*Eng. Cyc.*

(6017) PANICHIE, the Tamil and Portuguese names of a tree which grows in Ceylon and Travancore, from thirty to sixty feet high, and ten to twenty-four inches in diameter. In Ceylon it grows tall and straight, in Travancore it is not more than twenty feet high, and is curved. It produces a fruit which resembles externally the small russet apple: when pressed it yields a very glutinous juice, which is used as a substitute for glue; and may be considered in that country as very superior to glue for the use of joiners. In Ceylon this tree is converted into masts, yards, &c. for country vessels; and the native carpenters consider it the best sort of all the jungle woods for that purpose. — *Edye, Ceylon.*

(6018) PANICUM, a genus of Grasses the name of which is applied to one of the species (Millet) by the Romans, and which, Pliny states, is so-called from its flowers being in a panicle: though others derive the name from 'panis,' bread, from its uses as such. The genus contains a very large number of species, which abound in the hot parts of the world, though a few extend to higher latitudes and ascend the cool mountains of hot countries. They are chiefly valuable as pasture grasses, and for their seeds, which forms a large portion of the food of the poorer classes of many nations, and thus engage a considerable share of the attention of the agriculturists of those countries. The genus *Panicum* is distinguished by having a 2-flowered spikelet, with the lower flower masculine or neuter, and the upper hermaphrodite. Glumes 2, unequal, concave, blunt. Masc. paleæ 2, stamens 3, sometimes neuter, the upper palea and the stamens abortive. Fertile flowers, paleæ 2, unequal, concave, the lower one embracing the upper; scales 2; stamens 3; styles 2, ovary sessile. Besides those, mentioned below, which are the most commonly cultivated species, the grains of other species of *Panicum* growing in a wild state are collected, and form articles of diet with the poorer classes of the natives of India, as of *P. floridum* (Burtee), *P. Helopus* (Koorae), *P. hispidulum* (Dhand). The uses of this genus are not confined to its grain, for the herbaceous part of several species forms the most valuable pasture grasses of the hot countries both in the Old and New World. Some of the species of

Panicum of the Brazils are of gigantic stature, and yet tender and delicate in their herbage. The Coapim de Angola of Brazil grows 6 or 7 feet high, and other equally gigantic species constitute the field crops on the banks of the Amazonas; while *P. maximum*, or Guinea Grass, forms the most valuble pasture for cattle in Jamaica. This is said to have been introduced into that island from the coast of Africa, the seeds having been transmitted as food for some birds which were sent to Chief Justice Ellis. The straw of several of the species is esteemed as fodder for cattle in India, but no pasture grass in any country is probably more highly thought of than the Doob of India, which by the Brahmins is held sacred to Ganesha (Janus?) under the name of Doorsah. This is fortunately common throughout India, and forms probably three-fourths of the food of their horses and cows. It is seldom cultivated; but Europeans, in the northern parts, frequently form lawns by planting small pieces of this grass, which forms excellent hay. The usual mode of obtaining it is to send out the grass cutters into the uncultivated parts of the country, who scrape off the ground the creeping stems and leaves of this species, which is easily distinguished by its smooth and creeping habit; its spikes being fascicled and digitate, filiform, from 1 to 2 inches long, with the flowers disposed in two rows on the under side. It is the *P. Cynodon dactylon* of botanists, and occurs also in England.—*Eng. Cyc.*

(6019) PANICUM FRUMENTACEUM, the Shama or Samwuk of the natives of India, is a wholesome and nourishing grain, and forms there an article of diet, chiefly of the lower classes. There are several varieties of it, which yield from 50 to 60 fold; it delights in a light, tolerably dry, rich soil; the same ground yields two crops between the first of the rains in June, July, and the end of January, in the Circars, but only one crop in the northern provinces.

(6020) PANICUM ITALICUM. Setaria italica, *Kunth.*

Kungoo, Beng.	Tenney, Tam.
Kala-kanguee, Hind.	

India: cultivated in Europe. Seeds small, roundish, straw-coloured, pericarp brittle, with a round and partially pellucid grain, alimentary, but gives a heavy, disagreeable bread.—*O'Shaughnessy, page* 637.

(6021) PANICUM MILIACEUM, Millet. Common Millet. Lin. Κεγρος, Hesiod, Diosc. Hippoc.

Chamy, Can.	Samaloo, Tel.
Savee, cheena-waree, Hind.	Millet. Eng.
Varugoo, Tam.	Panicum Miliaceum
Shamakh, Duk.	Shamaka, Sans.
	Ainslie, page 217.

Millet, is the best known species, being cultivated in the south of Europe as well as in tropical countries. Two varieties are well known, one brown, the other yellow-coloured, imported from the Mediterranean chiefly for feeding poultry, but forming in the south of Europe as well as in India a portion of the food of the inhabitants. In the latter country it is cultivated in the cold weather with wheat and barley, and the only one of the small grains that is so at the season of the year.—*Ainslie. Eng. Cyc.*

(6022) PANICUM MILIARE, is another species generally cultivated on an elevated rich soil in the peninsula of India: the seed is one of the sorts of dry or small grain which forms an article of diet of the Hindoos, who inhabit the higher lands, and cattle are fond of the straw.—*Eng. Cyc.* Cultivated in Europe, seeds oval, slightly compressed, brilliant, about a line in length; bark or envelope blackish, brown or fair; parenchyme, white, or sweet taste. Alimentary, but the pericarp is very difficultly separated from the grain; chiefly used in a kind of gruel or bouillie.—*O'Shaughnessy, page* 637.

(6023) PANICUM. Panic grass. Several very common grasses belong to the genus panicum. One species in Tenasserim grows about three feet high, and after a field has been subdued, it will often spring up so thick that every thing else is destroyed. Cattle eat it both dry and green.—*Mason.*

(6024) PANICUM SEMIVERTICILLATUM. Rottler.

Koodraywalie chamay Tam. | Lupta Hind.

This is an inferior grain to several of those hitherto mentioned and is eaten by the poor people in the districts in which it is cultivated; such as Coimbatore, and other dry grain countries.—*Ainslie, p.* 219.

(6025) PANMUHORI. Seeds of Fæniculum Panmorium.—*Ben. Phar.*

(6026 PANNAM KALUNG. The people of Southern India and Ceylon have for many hundred years been in the habit of eating the bulb or root, which is the first shoot from the palmyra nut which forms the germ of the future tree, and is known locally as pannam kaling. It is about the size of a common carrot though nearly white. It forms a great article of food among the natives for several months in the year; but Europeans dislike it from its being very bitter. Recent experiments have proved that a farina superior to arrowroot can be obtained from it, prepared in the same way, and 100 roots, costing 2½d, yield one and half to two pounds of the flour.—*Simmonds' Comml. Products, p.* 376. In Madras, 100 cost 1½d.

(6027) PANRI. Leaves of a small plant imported from Bombay, considered refrigerant and to promote digestion: are sweet-scented, and used by attars; one seer costs one and a half rupees. —*Genl. Med. Top. p.* 149.

(6028) PAN SOOPAREE, from *Pan*, betel leaf, and soopeearee, areca nut; see BETEL.

(6029) PANSY, HEARTSEASE. May be raised from seed, sown at the commencement of the rains, will hardly repay the trouble.—*Jaffrey.*

(6030) PAPAVER, a genus of Plants the type of the natural order *Papaveraceæ*. The history of this, like that of many other cultivated plants, is little known, as well as the time when it began to be cultivated for the sake of its inspissated juice, though it was well known to the Greeks, and cultivated at very early periods on account of its seeds. (Theoph., lib. ix. cap. xiii., ed. Bodæus and Staple, p. 1097.) Some authors are of opinion that it is the Μήκων of Dioscorides, and that the kind with black seeds was called' Αγρία, and that with white seeds Ημερος; and that it is the juice of this plant which Hippocrates recommends under the name of ὀπός μήκωνος or 'juice of the poppy.' Pliny (xx. c. 18) uses 'opium' to express the inspissated juice of the poppy. Sprengel, in his 'Hist. Rei Herb.,' i. p. 176, quotes Diosc., lib iv. c. 65, as referring to *Papaver somniferum*, and to *P. Rhœas*; but in his edition of that author (ii. p. 600) he mentions only the latter plant; hence we may infer that he conceives the former to have been unknown, as he nowhere else mentions it. We do not in this instance get the same degree of assistance as in many others from Arab authors. Opium is described by them under the name of Afeeyon, while Apaynum is quoted by Dr. Ainslie as its Sanscrit name. The poppy plant is described by the Arabs under the name of Khushkhush, while the Sanscrit is Chosa; and the Persian and Hindoo, Post. The species of *Papaver* are chiefly found in European countries; but a few species expand to the Caucasus and Armenia, and one species grows in the Himalayas, though Egypt is the country where we find the earliest notice of the opium poppy. This species is now common in most parts of Europe, but having been so long cultivated, it may appear indigenous in many countries where it has only escaped from cultivation. It is, as is well known, extensively cultivated in India, but it can nowhere be seen in a wild state, as the climate is too hot to support it, except for a few months in the year. The genus *Papaver* has two convex deciduous sepals; petals 4; stamens numerous; style wanting; stigmas 4 to 20, radiating and sessile upon a disc which crowns the germen; capsule obovate, 1-celled, opening under the crown of the stigmas with short valves; placentæ intervalvular, incomplete; flower-stalks inflexed at the apex before the flowers have expanded; the flowers of all are large and showy, but last a short time. Herbaceous plants abounding in milky juice. The species are numerous. The English species are distinguished as having a rough and a smooth capsule; of the former, *P. hybridum* has an obovate globose capsule, and *P. Argemone* an elongated club-shaped capsule; of those smooth capsules, *P. Rhœas* and *P. dubium*, the former has a globose and the latter an oblong capsule.—*Eng. Cyc.*

(6031) PAPAVER CROCŒUM. This species, which is almost always variegated, is sown only as a border flower, for its large and handsome appearance The scent is anything but agreeable. The seed should be sown where the plants are to remain, and six inches the least space allowed between each plant. They do not bear transplanting. The common cultivated species, from the capsule of which opium is procured, is of various colours, and when sown in beds, has a very pleasing effect. The seed (kus kus) is usually used by natives in confectionery having the taste of sweet almonds. Is propagated by seed only.—*Riddell.*

(6032) PAPAVER RHŒAS, (corn poppy). This unimportant species is found in gardens in upper India. The petals are of a beautiful red colour, and are used to colour a syrup, the Syrups rhoœados of the English pharmacopœia; no active or narcotic principle has been found in this species.—*O'Shy., p.* 171.

(6033) PAPAVER SOMNIFERUM, OPIUM POPPY. Linn, The Garden or white Poppy. var. *a* with black, var *b* with white seed.

Post, HIND
Khuskush, ARAB. and DUK.
Koonar, PERS.
Chosa, SANS.
Μμκων GREEK.

It appears to have been one of the early cultivated plants, as Homer is thonght to allude to it as growing in gardens. Hippocrates mentions two kinds, the *black* and *white poppy*, so the Arabs and Persians distinguish the *khushhash abiuz* or white, from the *khushkhash aswad*, or black poppy. The white Poppy is now cultivated in the plains of India, and the black, or rather deep-red, variety in the Himalayan mountains. Mr. Hamilton says, "The opium is chiefly obtained from the single white poppy; I have also seen the red and purple colours though only one is usually seen in a field. I hardly remember to have noticed any mixture of colour in one piece of ground. The kind here cultivated generally grows to a height of three feet."—*Hamilton, Travels in Asia Minor p.* 115. It was early cultivated, as it still is, in Egypt, also in India, Persia. Asia Minor, as well as in some parts of Europe, The Garden Poppy is probably a native of Persia. It has, however, been so long grown in gardens in various parts, that it is sometimes found apparently wild, especially in the southern parts of Europe. The roots are from 2—4 feet high, the stems are round and straight, glaucous, smooth, with a few hairs towards the white and tapering

extremity, and on the peduncles. The leaves are large sessile, amplexicaul, smooth, of a glaucous green, margins wavy, cut and toothed. The flowers are large and terminal, drooping before flowering, with smooth concave sepals; 4 large petals, roundish in form, white or of a purplish colour with a darker coloured spot near the claws. The capsule is oval, or nearly globose, large, smooth, with parietal placentæ equal in number to the stigmas, which are covered with numerous white or brownish coloured, kidney-shaped seeds. Flowers in June and July, and the capsules ripen about two months later.—*E. B.* 2145. Some consider that there are two distinct species instead of varieties of this plant. *P. Officinale.* (Gmelin, var, *album* is larger and less glaucous, with white petals and seeds, capsules ovate-globose and remaining closed under the crown of stigmas while *P. somniferum* (Gm.) var. *nigrum* has the flowers violet or [illegible], seeds black, capsules globose, opening by foramina under the stigmas. The White Poppy is a native probably of Asia Minor, or of some part of the Persian region of botanists, but having been so long cultivated, is found wild in many parts of Europe. The species is distinguished by its obovate or globular capsules, smooth as well as the calyx, the stem smooth and glaucous, leaves embracing the stem incised and repand, with sub-obtuse teeth. There are two distinct varieties, which by some botanists are considerad to be distinct species: the dark, the red-flowered, and black-seeded is called by Gmelin *P. somniferum*; and the white flowered with white seeds, *P. officinale.* The latter is characterised as having an ovate globose capsule; foramina under the stigma either none or obliterated; peduncles solitary. The former (*P. somniferum*) has globose capsules, opening by foramina under the stigma; seed black; peduncles many. The flowers are usually red of different tints, though sometimes white. Dr. Royle states that he has seen only the white-flowered variety in the plains of India, and the red-flowered in the Himalayas, and both cultivated for the sake of the opium. The poppy is cultivated in many parts of Europe on account of its seeds, which yield a bland oil much esteemed in France; and in England chiefly on account of the capsules, which are used medicinally. It is extensively cultivated in Turkey and Asia Minor, Egypt, Persia, and India, on account of its inspissated juice, so well known as opium, though this is occasionally prepared also in Europe. The cultivation of the poppy is very simple, though the weeding requires care, and the plants must not be crowded too much together. They are carefully watered and manured, the watering being more copious as the period of flowering approaches, and until the capsules are half grown.—*Eng. Cyc.*

This most important plant is a native of the south of Europe and Asia Minor, and is now naturalized by cultivation in India. The *Capseeles* are employed in medicine for the preparation of a sedative decoction and syrup, much used for children. They are devoid of odour; of slightly bitter taste. If collected before the concrete juice is removed the capsules contain a minute portion of all the active principles of opium; for medicinal purposes those should be rejected which are marked with longitudinal and paralled cuts resulting from the extraction of opium. An infusion of poppy heads in cold water should strike a red colour with permuriate of iron—*O'Shaughnessy, page* 171.

Poppy Oil.—The seeds of the poppy yield by expression 56 per 100 of a bland and very valuable oil, of a pale golden colour, fluid to within 10 degrees of the freezing point of water; Sp. Gr. 939; it dries easily, is inodorous, of agreeable flavour, is partially soluble (8 in 1000) in alcohol, dissolves the oxides of lead. The mass from which the seed is expressed is found to be extremely nutritions to cattle; for all pharmaceutical purposes, this oil is equal to that of the olive, employed in European pharmacy, and accordingly recommended in Dr. O'Shaughnessy's formulæ for Hospital use.—*O'Shaughnessy, Eng. Cyc. page* 172.

Opium is an invaluable remedy, and important article of commerce, and requires to be treated of in considerable detail and reference is made to the article Opium.

(6034) PAPAVERACEÆ, *Poppyworts*, a natural order of Hypogynous Exogenous Plants. The species are readily known by their deciduous calyx, usually tetramerous flowers, indefinite hypogynous stamens, and parietal placentæ; added to which, they have leaves without stipules, and their stems discharge a turbid white, yellow, or orange-coloured juice when wounded. Their seeds moreover contain a bland oil, lodged in a copious albumen, within which is stationed a minute embryo. They consist for the most part of herbs, which are usually of only annual duration; but a few are shrubby, the most remarkable case of that kind being a genus called *Dendromecon* a native of California, which is a true shrub, with the aspect of a *Cistus.* The greater part of the species inhabit the temperate parts of the Old World; but a few also occur in Australia, at the Cape, and in South America. Their active qualities are usually deleterious, but are for the most part of little moment, except in the case of the *Papaver somniferum*, or Opium Poppy. It is however probable that in most cases the milky juice is narcotic, and the oil of the seeds harmless. An apparent exception to the latter statement occurs in *Argemone Mexicana*, the seeds of which are said to be narcotic, especially

when smoked; but it is probable that in this case it is in the coats of the seed that the poisonous principle resides, rather than in the oil itself. Some *Papaveraceæ* have no petals, as *Bocconia*, thus corresponding with *Thalictrum* and other apetalous *Ranunculaceæ*, with which order they are closely connected through *Platystemon*, a Californian annual with disjointed carpels. They are also related to *Nymphæaceæ* and *Sarraceniaceæ*. The order embraces 18 genera and 130 species.—*Eng. Cyc.*

(6035) PAPAW, CARICA PAPAYA. This is the American pawpaw, not the pawpaw of the Mississippi valley, *Porcelia triloba*; but the pawpaw of South America and the West Indies. Europeans call it papaya, from the Portuguese *papayo*; and by the Portuguese it was probably introduced into India, The fruit resembles a melon in appearance, and often tastes no better than a good English turnip.—*Mason*. The fruit and leaves of the papaw, or Muh-Kwa tree melon, are eaten, after being cooked; the Chinese are aware of the supposed intenerating property of the exhalation from the leaves of this tree, and make use of them sometimes to soften the flesh of ancient hens and cocks by hanging the newly killed birds in the tree, or by feeding them upon the fruit beforehand.—*Williams' Middle Kingdom, p.* 284.

(6036) PAPAYACEÆ. *Papayads*, a small natural order of Exogenous Plants. The species are apparently allied to *Cucurbitaceæ* and *Passifloraceæ*, with the former of which it corresponds in its gourd-like fruit, with parietal placentæ, and in its disunited sexes; while it approaches the latter also in placentation, in its superior succulent fruit, and in the structure of its seeds. The order is remarkable in its fructification for having monopetalous male flowers and polypetalous females, and in its vegetation for its simple unbranched stems, growing only by the gradual development of a terminal bud. The species of most importance in this order is the Papaw-Tree, *Carica Papaya*. The order as at present constituted contains 8 genera and 25 species.—*Eng. Cyc.*

(6037) PAPEETA: NUT OF Strychnos Sancti Ignatii *Ben p.* 219.

(6038) PAPER.

Karta, ARAB.	Kaghas, PERS.
Papiers, DUT.	Kaedum, TAM.
Papier, FR.	Kakitum, TEL.
Papier, GER.	Papel, PORT.
Kaghuz, Kaghul. GUZ HIND.	Bumaga, RUS.
Carta, IT.	Papel, SP.
Charta, LAT.	

In histories of the manufacture of paper, the Chinese are generally acknowledged to have been the first to have made paper from pulp. The Egyptian paper, or Papyrus, was made by gumming slices of vegetable tissue together under pressure, and what is called the Rice paper of China consists only of thin slices of cellular tissue of a plant. The Arabs are supposed to have learnt the art in the eighth century from the Chinese, but much more probably from the Hindoos, as they translated many of their works and adopted much of their science. The Arabs are further said to have introduced the art of paper-making into Spain in the ninth or tenth century. Paper was first made at Nuremburg in the year 1390, but in England not till the year 1450. There is no doubt however, that the manufacture of paper from pulp has been known in China from very early times: it is said for at least 2000 years. They employ a vast variety of fibrous substances for this manufacture, and apply paper to a variety of uses little thought of in other countries. They make up an infinite variety of kinds, from the coarse, heavy, half-inch thick touch-paper, for retaining a slow, enduring fire, to the beautiful so-called India paper suited for the finest proof engravings. In the tea chests there is a lavish use of many thicknesses of paper. If a hut or boat is leaky over-head, the bed is protected by a large sheet of oiled paper. If a shopkeeper wants to tie up a parcel, he seizes a strip of tough paper, and by rolling it on his thigh at once converts it into a strong packthread, and even a torn sail is at times patched with tough paper. In China it is the cheapest of materials in daily use, and the manufactures are very numerous. They make it of Rice straw, of young Bamboos, of different fibres, and of the bark of the Paper Mulberry; showing that the inventors of the art make use chiefly of unwoven fibres, though they also employ refuse cloth and silk, &c. So India, though hardly ever mentioned in histories of the art, is a country where considerable quantities of paper are made, though not generally of a good quality, as the thick ink in use does not so much require this. There are small manufactories of it in most parts of the country, and to a considerable extent at such places as Ahmedabad, Lucknow, Aurungabad, &c. As will have been seen in these pages, a great variety of fibres, such as Jute, Sunn, Ambaree, Moorva, and old sacks and fishing nets are also employed, though in general the natives of India, prefer the Sunn fibre. The Himalayan process with the inner bark of the Paper plant very much resembles that of the Chinese with the Paper Mulberry. It is probable therefore that the art was introduced from that country into the Himalayas, and not from India, into which it had probably been carried at a very early period, and from thence learnt by the Arabs; who would hardly else have used Cotton, an Indian product. The Hindoos themselves, according to Professor Wilson, still used, about the beginning of the Christian era, or as late as the age of their Dramas, the inner bark of the *Bhurja* or Birch (*Betula Bhojputtur*) for writing on. In the Southern regions of India the leaves of the Pal-

mira and of the Talipat are well known to have been long used, as they still are, for writing on with a style. But the manufacture of paper from pulp has long been established in India, and before the Arabs began to make translations from the Sanscrit, at the same time that they did so from Greek writers. Dr. Buchanan, in his survey of the lower provinces of the Bengal Presidency, has given an account of the manufacture of paper from Pat or Jute (*Corchorus olitorius*) at Dinagepore, and in Behar, &c., from Sunn (*Crotalaria juncea*). It is also so made in other parts of the country, as well as from Hibiscus fibre. And there can be no difficulty in doing so with the other numerous fibrous materials which India produces in such vast variety. It is objected by manufacturers of paper that pulp from unwoven fibres does not draw through the present machinery so well as that made from rags. A modification of machinery would remedy this. But it is probable that if the half-stuff were made from the clean bark without first separating the fibres, these might probably be so entangled as to answer some of the effects of the weaving. As rags have to be collected, cut, cleaned, and bleached, Dr. Royle thinks that the primitive method of using the bark of suitable plants and trees will afford both a cheap and an effectual substitute. Besides which, the supply of rags must come short of the increasing demands of the world for paper. Bengal and the east coast of the Bay of Bengal, as well as the Malabar or west coast of India, are the places where the growth of suitable materials, from the warmth and moisture of the climate, is most abundant, and the conveyance by sea is at the same time most easy. In Arracan the price of Bast, even made into rope, is but one rupee per maund, and Mr. Henley observes that "it is to India we must look for extensive and cheap supplies, for it is there alone we find the necessary conditions of very low-priced and intelligent labour, with an abundance of elementary suitable materials; and that as articles of small price are particularly sensitive of charges, such as of freight, &c., it is only by large operations that an average of low charges can be accomplished." Suitable materials being abundant, he proposes that it should be reduced to the state of half-stuff by the aid of the Dhenkee, already mentioned as an instrument to be found in almost every house in Bengal, being used for husking rice, the preparation of tobacco, of drugs, stuffs, and brick dust. "The method proposes to avail itself of one of their own simple arts; it brings the question as nearly as possible to the state of a domestic industry, ever the most economical in such countries; it reduces to the lowest point the charge of collecting from extensive districts the various elementary matters which might present themselves." Dr. L. Playfair observes, that the price of 2*d.* to 2½*d.* per lb. for a partially prepared pulp, is by most makers considered to be too high, and that materials should be looked for at 1*d.* to 1½*d.* per lb. roughly prepared pulp; but if bleached or in as far an advanced state with regard to colour and texture as cotton or linen rag, then 2½*d.* to 4*d* per lb. might be obtained. To serve as points of comparison we may here insert a notice of the ordinary and the lately increased prices of rags from the 'Journal of the Society of Arts.'

A.	26*s.*	.....	32*s.* to 34*s.* per cwt.
B.	16*s.*	.....	20*s.* ,,
C.	11*s.* 6*d.*	.....	15*s.* ,,
D.	7*s.*	.....	10*s.* ,,

Bleaching salts, alkali, alum, hide pieces for size, are other articles required; and all have increased in price. Of the quantity of paper making material required, some idea may be formed from the fact that 177,633,009 lb. weight of paper were produced in 1853 in Great Britain. Paper is, in Europe, made chiefly from linen or cotton rags, but also from the refuse and sweepings of cotton-and flax-mills, as also of the coverings of our cotton bales and of worn-out ropes. Paper is also made from the stems and leaves of many grasses, as from rice straw, and from the bamboo by the Chinese, and of late from common straw in this country, and even from wood shavings. The fibrous part of many Lily and Aloe-leaved plants have been converted into excellent paper in India, where the fibres of Tiliaceous, Malvaceous, and Leguminous plants are employed for the same purpose: as in the Himalayas, one of the Lace-bark tribe is similarly employed, and in China one of the Mulberry tribe, and the Nettle in Holland. Plants belonging to the same families as the above abound in India and other warm countries, and are capable of yielding a very abundant and never-failing supply of sufficiently cheap and very excellent material for paper-making of all kinds. Some may be used without any further process of bleaching, but all are capable of having any colour they may possess destroyed by chemical means not excepting even the jute canvas or gunny bagging because specimens of jute of a beautiful silk, white, both plain and manufactured into fabrics for furniture, &c, &c., were shown by the late Colonel Calvert at the East India House. As the Chinese make paper of rice straw, and of the young shoots of the bamboo, while the Hindoos make ropes of different grasses (such as *Saccharum Munja* and *S. Sara*) strong enough for their Persian wheels as well as for towing lines, it is evident that these, and probably many others, contain a sufficiency of fibrous material for paper-making. The cultivated Cereals cannot well be turned to much account, for their straw forms the chief food for cattle; but as Southern Asia abounds with grass jungles, which are in the autumn of every year

burnt down in order that the young blades may spring up and afford pasturage for cattle, it is evident that there are many situations where a sufficiency might be cut down before it has become perfectly dried up, and converted into half-stuff for paper-makers and the refuse of the Sugar-cane might be similarly employed. Of the Sedges in India, some are employed for making ropes, as the Bhabhur or *Eriophorum Cannabinum*, for making rope bridges for crossing some of the hill torrents, and the *Cyperus tegetum*, is used in India for mat-making. As these plants as well as Rushes grow together in large quantities, it would be quite possible in many places to turn them to profitable account. Many parts of the world abound in the Lily and Aloe-leaved plants which have been alluded to above, and of which the leaves contain much easily separable fibrous materials. These belonging to the genera Agave, Aloe, Yucca, Sanseviera, Bromelia, and others, all of which abound in white-coloured fibres, applicable to various useful purposes, and of which the tow might be used for paper-making, and considerable supplies obtained. Paper used to be made from the Sanseviera in Trichinopoly, some has been made at Madras, of the unbleached Agave alone, as also mixed with old gunny bags. And recently also, from the leaf of the Pandanus. The Arrow root and Ginger tribes, containing such plants as those yielding the fecula called Arrow-root, Tous les Mois, Tikkur, &c, and Ginger, Turmeric, Cardamoms, &c., all have annual stems and leaves, which are the refuse of the present culture, and might yield an abundant supply of half-stuff. Among cultivated plants there is probably no one so well calculated to yield a large supply of material fit for making paper of almost every quality as the Plantain (*Musa paradisiaca*) so extensively cultivated in all tropical countries on account of its fruit, and of which the fibre-yielding stems are applied to no useful purpose. The plant, as every one acquainted with tropical countries knows, is common near the poorest huts and in the largest gardens, and is considered to yield by far the largest quantity of nutritious matter. Its fruit in many places supplying the place of bread, and in composition and nutritious value approaching most nearly to the potato, may, if produced in too large a quantity, be preserved in the same way as figs, or the meal may be separated, as it resembles rice most nearly in composition. Each rootstock throws up from six to eight stems, each of which must be yearly cut down, and will yield from three to four pounds of the fibre fit for textile fabrics, for rope-making, or for the manufacture of paper. As the fruit already pays the expenses of the culture, this fibre could be afforded at a cheap rate, as from the nature of the plant, consisting almost only of water and fibre, the latter might easily be separated. One planter calculates that it could be afforded for £9 13*s*.4*d*. per ton. Some very useful and tough kinds of paper have been made in India from the fibres of the Plantain, and some of finer quality from the same material both in France and in England. All the plants which have been already mentioned are devoid of true bark, and are called Endogenous in structure. Simple pressure between rollers, and washing, would appear to be sufficient for the separation of the fibres of most of them. But the following families of plants are all possessed of true bark which requires to be stripped off, usually after the stems have been steeped in water, before their respective fibres can be separated from the rest of the vegetable matter. The Flax plant abounds in fibre, but this is too valuable to be converted into paper. India, however, grows immense quantities of the plant, on account of its seed (linseed) which is both consumed in the country and exported in enormous quantities. But nowhere is the fibre turned to any account. This is no doubt owing to the climate not favouring the formation of soft and flexible fibre; but the short fibre which is formed, and might be easily separated, would be valuable for paper-making, and might add to the agriculturists' profits without much additional outlay. So some Malvaceous plants are cultivated on account of their fruits being used as articles of diet, as Okhro (*Hibiscus esculentus*), in the West Indies and in the United States. The *Ram Turai* of India is closely allied to it, and is cultivated for the same purpose. Both plants abound in fine flexible fibre, which is not, but might be easily separated, and afford a considerable supply, especially if the cultivation was extended in the neighbourhood of towns. Paper is made from a species of *Hibiscus* in Japan, and *H. Sabdariffa* is cultivated in India on account of its jelly-yielding calices. Numerous other species of Hibiscus, of Sida, and of other genera of this family, abound in warm climates; several are cultivated in different countries, as *Hibiscus cannabinus* in India, and *Sida tiliæfolia* in China, might be more so. They grow quickly, and to a large size, and abound in fibrous material of a fine, soft, flexible quality: on which account they might be cultivated with profit, and the tow be useful to the paper-maker. The stems of Cotton plants would also yield a supply. The Tiliaceæ are likewise remarkable for the abundance and fine quality of fibre which many of them contain. *Tilia europea* produces the enormous quantities of bast exported from Russia. *Corchorus olitorius* and *C. capsularis*, the leaves of both of which are used as a vegetable, yield the Jute of commerce, as well as the gunny cloth and bags so largely used and exported even to America. Several species of Grewia yield an edible fruit, on which account they are cultivated. Others abound in the jungles of South-

ern Asia, and most would yield a valuable fibre, as some of them already do, for commercial purposes. The Indian Basts are cheap, and abound in fibre. Some of the Leguminosæ also abound in valuable fibre. *Crotalaria juncea* yields the common *Sunn* of India. *Sesbania aculeata* or *cannabina* yields the *Dhanchi* of Bengal; while *Bauhinia racemosa* is used for making rope bridges in the Himalayas. The fibre of *Parkinsonia aculeata* was sent to the London Exhibition of 1851, expressly as being fitted for paper making: though colourless, it wants strength. Some paper is made from gunny bags in India. Several plants produce large quanties of a silky cotton like substance, not applied to any use, such as the Silk Cotton tree, the Mudar of India, several species of Saccharum, &c., which might be collected where labour is cheap, and would no doubt be well fitted for conversion into pulp for paper. The Dogbanes and Asclepiads, also deserve attention. The Nepal Paper plant *Daphne cannabina* has been mentioned above. Among the Nettle, the Mulberry, and Bread-fruit tribes of plants, there are many which seem well calculated to yield material for paper-making. The Chinese, we know, employ the inner bark of *Morus*, now *Broussonetia papyrifera*. This, no doubt, produces some of the Chinese papers, which is remarkable for toughness. The refuse cuttings of the bush cultivation of the Mulberry in Bengal might be turned to profitable account. The barks of many stinging (*Urtica*), and of stingless (*Boehmeria*) Nettles, abound in fibres remarkable for strength; the tow of these might be converted into paper-stuff, if not required for mixing with wool, as might also the bark cloths. The weeds of tropical countries, which grow in such luxuriance, and among which are species of Sida, of Grewia, of Corchorus, of Triumfetta and of many other genera, might all yield an abundance of fibrous material, if the refuse of the above cultivated plants were found not to be sufficient. Some simple machinery for separating the fibre would greatly facilitate operations, while the expenses of freight might be diminished by compression, or as suggested, by packing the material as dunnage. The cheapness of labour, as of everything else in many of these countries, would enable material for paper-making to be conveyed to England in great abundance and at a sufficiently cheap rate, if ordinary pains were taken by the consumers in Europe, to encourage the planter or colonists of a distant region. Dr. *Forbes Royle*. East India House, May 3, 1854. Paper is a thin flexible leaf usually white, artificially prepared from some vegetable substance, chiefly for writing or printing upon with ink. A species of paper was manufactureed at a remote period in Egypt, from the *papyrus* or *paper-reed*, a plant growing freely on the banks of the Nile. A manufacture of paper from the bark of trees and other substances existed also in China, from a very early date; but among the nations of antiquity, before the introduction of paper, such substitutes were used as lead, brass, bricks, and stone, on which national edicts and records were written or engraved; or tablets of wood, wax, and ivory, skins of fishes, intestines of serpents, backs of tortoises, and the inner bark of trees for ordinary purposes. Indeed there are but few sorts of plants that have not been used for making paper and books, and hence have arisen the terms *biblos*, *codex*, *liber*, *folium*, *tabula*, *tillura*, *philura*, *scheda*, &c., which express the several parts of the plant which were written on. The use of these was discontinued in Europe after the invention of papyrus and parchment, but they are still used in other parts of the world. The two early kinds of manufacture above alluded to, must first be noticed, before we describe the later invention of making paper from cotton and linen rags, which in the greater part of the world has superseded all other methods of producing a material for writing on. The Egyptian papyrus was made by laying thin plates of bark, taken from the middle of the paper-rush, side by side, but close together, on a hard smooth table: other pieces of the same size and thinness were then laid across the first at right angles; the whole was moistened with the water of the Nile, which was supposed to have some agglutinating property, (though this probably resided in the plant itself,) and pressure was then applied for a certain number of hours. Thus a sheet of paper was formed which required no other finishing than rubbing and polishing with a smooth stone, or with a solid glass hemisphere, and drying in the sun. This very simple process was rather a preparation of a natural paper, than a manufacture—properly so called. The process adopted by the Chinese comes more legitimately under that head. The small branches of a tree resembling our mulberry-tree, are cut by them in lengths of about 3 feet, and boiled in an alkaline ley for the sake of loosening the inner rind or bark, which is then peeled off, and dried for use. When a sufficient quantity of bark has been thus laid up, it is again softened in water for 3 or 4 days, and the outer parts are scraped off as useless; the rest is boiled in clear ley, which is kept strongly agitated all the time, until the bark has become tender, and separates into distinct fibres. It is then placed in a pan or sieve, and washed in a running stream, being at the same time worked with the hands, until it becomes a delicate and soft pulp. For the finer sorts of paper the pulp receives a second washing in a linen bag; it is then spread out on a smooth table, and beaten with a wooden mallet, until it is extremely fine. Thus prepared, it is put into a tub with a slimy infusion of rice, and a root called oreni; then it is stirred until the ingredi-

ents are properly blended: it is next removed to a large vessel to admit of moulds being dipped into it. These moulds are made of bulrushes cut into narrow strips, and mounted in a frame; as the paper is moulded, the sheets are placed on a table covered with a double mat. The sheets are laid one on the other, with a small piece of reed between; and this, standing out a little way, serves afterwards to lift them up leaf by leaf. Every heap is covered with a board and weights to press out the water; on the following day, the sheets are lifted singly by means of the projecting reeds, and are placed on a plank to be dried in the sun. This paper is so delicate, that only one side can be written on, but the Chinese sometimes double the sheets, and glue them together so neatly, that they appear to be a single leaf. This manufacture of the Chinese extended also to the making of sheets of paper from old rags, silk, hemp, and cotton, as early as the second century of the Christian era, and is supposed to have been the source whence the Arabs obtained their knowledge of paper-making. The latter people first introduced the valuable art of making paper from cotton into Europe, in the earlier half of the twelfth century, and established a paper manufactory in Spain. In 1150, the paper of Xativa, an ancient city of Valencia, had become famous, and was exported to the East and West. Notwithstanding its fame, this paper was of a coarse and inferior quality, so long as its manufacture was confined solely to the Arabs, in consequence of their employing only mortars, and hand or horse mills for reducing the cotton to a pulp; but when some Christian labourers obtained the management of the mills of Valencia and Toledo, the different processes of the manufacture were greatly improved. Cotton paper became general at the close of the twelth and beginning of the thirteenth centuries, but in the fourteenth century, it was almost entirely superseded by paper made of hemp and linen rags. The paper made of cotton was found not to possess sufficient strength or solidity for many purposes; a very strong paper was therefore made of the above substances, not weakened by bleaching, according to the present mode, which, by removing the natural gum, impairs the strength of the vegetable fibre. Some of these old papers, having been well sized with gelatine, are said to possess their original qualities even to this day. The manufacture of paper from linen rags became general in France, Italy, and Spain in the fourteenth century; the first German paper-mill was established at Nuremberg in 1390. English manuscripts on linen paper, date as early as 1340; but it is believed that the manufacture did not exist here until the end of the fifteenth century, when the *Bartolomæus* of Wynkyndde Worde appeared (1496), in which it is stated that paper of a superior kind was made for that work by John Tate, jun., at his mills in Stevenage, Hertfordshire. Probably the manufactory established by Tate was unsuccessful, for we hear no more of it, and in 1588 a German named Spielman, jeweller to Queen Elizabeth, established a paper-mill at Dartford. [This mill is celebrated by a poet of that age in a work entitled, "A Description and Discourse of Paper, and the benefits it brings; with the setting forth of a paper-mill, built near Dartford, by a High-German, called Mr. Spilman, jeweller to the Queen. Lond. 1588. 4to."] Still for a lengthened period England's supply of the finer kinds of paper was chiefly obtained from abroad. In 1770 the manufacture of fine paper was established at Maidstone, in Kent, by a celebrated maker, J. Whatman, who had worked as journeyman in some of the principal paper-mills on the Continent. Not long before this, *wove* moulds had been invented by Baskerville to obviate the usual roughness of *laid* paper, and these, attracting attention in France, led to the improvements which characterised the vellum paper of that period. Holland, too, contributed its share to the advancement of this manufacture, by inventing cylinders with steel blades for tearing the rags, and thus facilitating their conversion into pulp, which by the old method of stampers only, was a very slow and defective process. In 1799 the first attempt to produce paper in an endless web was made in France by a workman in the employ of M. Didot. The invention was brought to England by M. Didot in 1801, and made the subject of patents, which in 1804 were assigned to the Messrs. Fourdrinier. Mr. Bryan Donkin the engineer, carried out the desired plans, and produced, after intense application, a self-acting machine or working model, on an improved plan, of which he afterwards constructed many others for home use and for exportation, which were perfectly successful in the manufacture of continuous paper. In the year 1851 Messrs. Donkin & Co. were constructing their 191st machine. In 1809 Mr. Dickinson, the celebrated paper-maker, invented another method of making endless paper, the highly ingenious details of which will be noticed hereafter. The Fourdrinier machines have been greatly improved by the inventions of Mr. T. B. Crompton, Mr. Brown, of Esk Mills, near Edinburgh, Mr. Ibotson, of Poyle, and other skilful manufacturers, English and foreign; so that at the present time, England, which was long dependent for its supplies on foreign countries, is not only able to produce an abundant supply for home use, but to export paper to a considerable amount. At one time there were serious apprehensions that the supply of linen rags would fail, and various researches were entered upon by ingenious individuals to find substitutes. A book written in German by M. Schaffers so long ago as 1772, [Sammtliche Papierversuche von Jacob Christian

Schaffers, Prediger zu Regenburg. *Regensburg*, 1772.] contains 60 specimens of paper made of different materials. This ingenious person made paper from the bark of the willow, beech, aspen, hawthorn, lime, and mulberry; from the down of the asclepias, the catkins of black poplar, and the tendrils of the vine; from the stalks of nettle, mugwort, dyer's weed, thistle, bryony, burdock, clematis, willow-herb, and lily; from cabbage-stalks, fir-cones, moss, potatoes, wood-shavings, and saw-dust. Paper has been likewise made from straw, rice, hop-bine, liquorice-root, the stalks of the mallow, and the husks of Indian-corn. The fear of a failure of linen rags, and the consequent necessity for these experiments, were obviated by the discovery of chlorine. This powerful bleaching agent will restore many varieties of coloured linen to its original whiteness, as well as discoloured papers and manuscripts, so that the same substances may be used over and over again as a material for paper.—*Tomlinson.*

(6039) PAPER, BURMESE, PAPER PLANT. The Burmese make a coarse paper from the bark of a large creeper, a species of Daphne, that is found in the forests. The paper is as thick as paste board, and the surface is blackened and written upon with a steatite pencil. Mr. Mason had never seen the plant in flower, but it is probably a species of Daphne.—*Mason.*

(6040) PAPER, CHINESE, OF BAMBOO, such as that on which the Hon'ble Mr. Morrison's book was printed, was manufactured from the common yellow bamboo paper of the Chinese by sizing it in water saturated with alum, to which glue is added; the sheets are dried and smoothed by rubbing them on a warm wall. The glazing which is upon writing paper is made by waxing the sheet, and afterwards rubbing it with a smooth stone; two, three, and four sheets are made into one thick sheet for ledgers, or other account books, by the same process, after wetting the inner surfaces with glue water, and drying the sheet in the sun. There is also a thin paper, called Nanking paper, which is manufactured from cotton wool, that is tougher and more flexible than the bamboo paper. Colored paper is exported in considerable quantities; the exportation of all kinds is principally to India and the archipelago. The consumption of Chinese writing paper is great in that part of the world, on account of its not being injured by the climate; foreign paper sized with glue being liable to spoil.—*Morrison.* Mr. Fortune tells us that in the canals near the city there were large quantities of bamboos partially covered with mud so as to be pressed under water. These were intended to be made into paper after they had been soaked for some time. The whole of the process of making paper from the bamboo did not come under his notice while travelling in the country, but it is carried out somewhat in the following manner:—After being soaked for some time in the way noticed, the bamboos are split up and saturated with lime and water, until they become quite soft. They are then beaten up into a pulp in mortars, or where water-power is at hand, as in the hilly districts, the beating or stamping process is done by means of stampers, which rise and fall as the cogs which are placed on the axis of the water-wheel revolve. When the mass has been reduced to a fine pulpy substance it is then taken to a furnace and well boiled until it has become perfectly fine, and of the paper consistency. It is then formed into sheets of paper. Bamboo-paper is made of various degrees of fineness, according to the purposes for which it is intended. It is not only used for writing upon and for packing with, but a large quantity of a coarse description is made for the sole purpose of mixing with the morter used by bricklayers. It was in the fields about Cading he found two fine species of carabus, under stones, which were highly prized by entomologists at home. On the first discovery of these insects he showed them to a group of children who were with him, and offered to buy all they brought, at the rate of thirty cash for each perfect specimen.—*A Res. among the Chi. p.* 333.

(6041) PAPER, COUNTRY.

Naat Cardasie, TAM.	Nulla kakidum, TEL.
Kagus, DUK.	

The coarse kind of paper prepared by the natives in Madras, was in Ainslie's time commonly made of old gunny bags or old fishing nets. In the process lime water and rice cunjee were employed and frequently a little Indigo to give it a blue tinge. Supposing from the whiteness and great tenacity of the Marool (or Munchie) nar that a valuable kind of paper might be prepared with it, he recommended a trial of it to the paper makers at Trichinopoly, in July 1813. They hesitated, never having heard that paper can be made from this substance, but were induced to make the experiment, and succeeded in making a much better and whiter paper than what is commonly made with old gunny bags. He could not learn that Paper is ever made in India as it is in the Ava dominions, either from the bark of the paper Mulberry (Morus papyrifera,) or from the macerated filaments of the Bamboo.—*Ains. Mat. Med. p.*190.

(6042) PAPER HANGINGS. Paper stained or printed with tasteful designs, and used for pasting on the walls of a room &c. There are many varieties, which are manufactured in England, France, Germany,

(6043) PAPER, HIMMALAYAN. The art of making paper is considered to be a Chinese invention, but it has long been known in India, where paper is made both of cotton and of the substitutes for hemp and flax. In the Himalayas it is made of the inner bark of *Daphne Cannabina*, and in sheets of immense size. A large

collection was exhibited from different parts of India, but, though well adapted for writing on, in India, it is not suited for Europe, in consequence of the difference in the ink used.—*Royle, Arts &c. of India, p.* 486.

(6044) PAPER, MULBERRY, BROUSSONETIA PAPYRIFERA, is a native of the i-les of the Southern ocean, as well as of China and of Japan. It has long been famous for its fibrous bark, which is made into a kind of cloth, as in Otaheiti and in the Sandwich islands, as well as into paper, in Japan. In making this paper the bark is boiled into pulp in a ley of wood ashes, and then well washed by agitation of it in water, until it becomes like tufts of tow. If too much boiled, the paper will be weak but white; and if insufficiently washed it is coarse but strong. It is then heaped on a table and beaten into a pulp, by batons of hard wood. Mucilage obtained from boiled rice, or from a plant called oreni, is added to the pulp, which is stirred with a clean reed until reduced to a homogenous liquor, and when of a due consistence it is ready for conversion into sheets of paper.

(6045) PAPER-NAUTILUS. [OCTOPODA].

(6046) PAPER PLANT OF NEPAUL is Daphne Bholua or Cannabina, one of the same family as the Lace Bark Tree, Daphne Legetta, now called Lagetta lintearia, of the West Indies. It is supposed to be identical with the D. Odora of Thunberg. It is extremely abundant in the Himalayas, and the paper is made by boiling the inner bark, in a ley of wood ashes, and reducing them to pulp by beating. Daphne or Gnidia eriocephala is very common on the Western Ghauts, and on the hilly parts of the Southern Mahratta country and Dekhan. On a trial of the paper by an engraver, he reported it as affording finer impressions than any English made paper, and nearly as good as the fine Chinese paper which is employed for what are called India paper proofs. Dr. Campbell describes the paper as strong and durable as leather.

(6047) PAPER, RICE. As this, says Fortune, was my first visit to this fine island and as I knew we had only a short time to stay, I lost no time in going on shore. Before leaving the vessel, I had been examining with a spy-glass some large white flowers which grew on the banks and on the hill-sides, and I now went in that direction in order to ascertain what they were; when I reached the spot where they were growing, they proved to be very fine specimens of Lilium japonicum—the largest and most vigorous I had ever seen. As I was admiring these beautiful lilies which were growing as wild as the primroses in woods in England, another plant of far more interest caught my eye. This was nothing less than the rice-paper plant—the species which produced the far-famed rice-paper of China named by Sir W. Hooker Aralia papyrifera. It was growing apparently wild, but the site may have been an old plantation, which was now over-grown with weeds and brush-wood. The largest specimens which came under my notice were about five or six feet in height, and from six to eight inches in circumference at the base, but nearly of an equal thickness all up their stem. The stems, which usually bear all the way up, were crowned at the top with a number of noble looking palmate leaves on long footstalks, which gave to the plant a very ornamental appearance. The under side of each leaf, its footstalk, and the top part of the stem, which was clasped by these stalks, was densely covered with down of a rich brown colour, which readily came off upon any substance with which it came in contact. I did not meet with any plant in flower during my rambles, but it is probable the plant flowers at a later period of the year. It flowers and seeds during the winter and spring months at Hong-kong and Calcutta. Numerous small plants are coming through the ground in various directions, which a Chinese soldier carefully dug up for me, and which I took with me to Shanghae and deposited in Mr. Bealis' garden. These, with a few samples of the largest stems I could find, have been sent to England and India; the latter will prove an interesting addition to our museums of vegetable productions. The proportion of pith in these stems is very great, particularly near the top of vigorous growing ones, and it is from this pure white substance that the beautiful article erroneously called "rice-paper" is prepared. The Chinese call this plant the Tung-tsaou. What it was, or to what part of the vegetable kingdom it belonged was long a mystery to botanists, who were often times sadly misled by imaginary Chinese drawings, as some of those which have been published will clearly show, now that our knowledge has increased. Indeed the only drawing I have seen in Europe, which has any claim to be considered authentic, is that brought from China by the late Mr. Reeves many years ago, and which I have seen in the library of the Horticultural Society of London. The Tung-tsaou is largely cultivated in many parts of the island of Formosa, and with rice and camphor forms one of the chief articles of export. Mr. Bowring, who read a paper upon the rice-paper plant, before the China branch of the Royal Asiatic Society, informs us that the Canton and Fokeen provinces are the chief consumers, and that the town of Foo-chow alone is supposed to take annually not less than 30,000 dollars' worth of this curious and beautiful production. The cheapness of this paper in the Chinese market, as Mr. Bowring justly remarks, is evidence of the abundance of the plant in its place of growth, and more especially of the cheapness of labour. "That 100 sheets of this material (each about three inches square), certainly one of the most beautiful and delicate substances with which we

are acquainted, should be procurable for the small sum of 1½d. or 1¾d., is truly astonishing: and when once the attention of foreigners is directed to it, it will doubtless be in considerable request among workers in artificial flowers in Europe and America, being admirably adapted to their wants." The larger sheets, such as those used by the Canton flower-painters, are sold for about 1½d. each. If the Tung tsaou proves hardy, in England, its fine foliage will render it a favourite amongst ornamental plants in English gardens. Judging, however, from its appearance when growing on its native island, and from the temperature of Formosa, I fear we cannot expect it to be more than a greenhouse plant with us. Before I left China, it has been completely naturalised on the island of Hong-kong. A noble plant was growing in the garden head quarters house: several very fine ones were observed in Messrs. Jardine's garden at East point, to which Mr. Bowring had introduced it, and younger plants were seen springing up in all directions. It is really a most striking looking plant and highly ornamental. At all times the fine, broad palmate leaves which crown the stem have a noble appearance, and in the winter months its large panicles of flowers make it more interesting — *A Res. among the Chi. p.* 231. The paintings on Chinese pith paper, or *rice paper*, as it is commonly but incorrectly called, are much sought after for their splendid colorings. This substance, whose velvety surface contrasts so admirably with brilliant colors, is a delicate vegetable film, consisting of long hexagonal cells whose length is parallel to the surface of the film, and which are filled with air when the film is in its usual state; the peculiar softness which so well adapts it for receiving colors is owing to this structure. Mr. Williams says it is obtained from a plant allied to the Artocarpus or bread-fruit, growing in the western provinces, but no very accurate information is possessed of its habits or appearance; some say it is a water plant. The pith is carefully taken out and cut in sheets by running a knife around it, and smoothing them with an iron. When the tissue breaks, the fracture is connected by a lamina of mica. An india-ink outline is first transferred by damping and pressing it upon the paper, when the ink strikes off sufficiently to enable the workman to fill up the sketch; one outline will serve for limning several copies, and in large establishments the separate colors are laid on by different workmen.

ture of these paintings at Canton een two and three thousand hands. ie sometimes used by the Chinese more remarkable for its singularity , is the reticulated nerve-work of the fleshy green part of the leaf removed by maceration, and the ed with isinglass. The appearance of a painting on this transparent substance is pretty, but the colors do not retain their brilliancy.—*Williams' Middle Kingdom, Vol.* II. *p.* 145. *Eng. Cyc.*

(6048) PAPER OF THIBET. Most of the paper used in Thibet is made from the bark of various species of *Daphneæ*, and especially of *Edgeworthia Gardneri*, and is imported from Nepal and Bhotan; but the Tibetans, as MM. Huc and Gabet correctly state, manufacture a paper from the root of a small shrub: this I have seen, and it is of a much thicker texture and more durable than Daphne paper. Dr. Thomson informs me that a species of Astragalus is used in western Tibet for this purpose, the whole shrub, which is dwarf, being reduced to pulp.—*Hooker, Him. Jour. Vol.* II. *p.* 162.

(6049) PAPIER MACHE. A name properly applied to articles composed of paper-pulp, boiled in a solution of gum or size to give it tenacity, and then pressed into moulds; though the term is also applied to trays, snuff-boxes, and other things made by glueing several piles of paper together, and then varnishing. Birmingham is the chief seat of this manufacture.—*Faulkner.*

(6050) PAPILIO, a genus of Lepidopterous Insects, established by Linnæus, and divided by subsequent entomologists into many groups and genera. It includes that very natural and beautiful assemblage of insects popularly known as Butterflies. The first section of *Lepidoptera*, named *Rhopalocera* (club-horned) in the arrangement of Boisduval, and *Diurna* in that of Latreille, corresponds with the Linnæan genus *Papilio*. The insects composing it have mostly thin and elongated antennæ terminated by a club. They are all day-fliers. Their larvæ, which are variously shaped, have six pectoral, eight abdominal, and two anal feet. The pupæ are usually angulated and, with a few exceptions, naked. The perfect insect varies in size from less than an inch across the wings when expanded, to nearly a foot in breadth. Equally variable are their colouring and outlines. They are short-lived. Their powers of flight are very great, and the mode of flight varies in the several species. The males are usually more gaily coloured than the females.—*Eng. Cyc.*

(6051) PAPILIO MACHAON. Choongtam in Sikhim boasts a profusion of beautiful insects, amongst which the British swallow-tail butterfly (*Papilio Machaon*) disports itself in company with magnificent black, gold, and scarlet-winged butterflies, of the Trojan group, so typical of the Indian tropics.—*Hooker Him. Jour. Vol.* II. *page* 26.

(6502) PAPYRUS, a genus of Plants belonging to the natural order *Cyperaceæ*. This generic term has been derived from the name of a

water plant, whose soft cellular flower-stem afforded the most ancient material from which paper was prepared, and our English word paper is derived from it. It has a stem from 3 to 6 feet high, with 3 acute angles, one of which, according to Bruce, is always opposed to the current of the stream in which it grows, as if to break its force. Its leaves are long and grassy, with a sharp keel. The flowers, which are green, are produced in very large compound umbels, with extremely numerous drooping triangular slender radii, terminated by very long filiform involucral leaves, within which are placed the spikes of flowers, each consisting of from 6 to 13 florets. It has been regarded as a species of *Cyperus*, and called *C. Papyrus*. It is also considered a distinct genus, and is named *Papyrus antiquorum*. It is a very common plant in Abyssinia, Egypt, and Syria, and is also met with in Calabria and Sicily; in gardens it is not uncommon. It inhabits both stagnant waters and running streams, and, independently of its ancient employment in the fabrication of paper, has been applied to other uses. The flowering stems and leaves are twisted into ropes; the roots are sweet, and have been employed as food. In Abyssinia boats are constructed from it, according to Bruce. In Syria the plant is called Babeer.—*Eng. Cyc.* A curious correspondence has taken place between M. Egger, a member of the Institute of France, and M. Firmin Didot, the printer and publisher, on Ancient substitutes for Paper. M. Rhizo Rhangabe, now Minister of Foreign Affairs in Greece, published, some time since, a copy of the remaining portions of an inscription detailing the expences incurred by the Athenians in the construction of the Erectheion, in the year before Christ 407. M. Egger drew the attention of M. Didot, by letter, to two of the items published by M. Rhangabe, in which, the cost of two tablets for writing the accounts on is given at one drachma (nearly 9d.) each, and the price of two leaves of paper for copies at one drachma and two oboli (or nearly 1s.) each. M. Egger states, that these accounts were drawn up on wooden tablets coated with white wax, like those used for the annals of the Roman Pontiffs, and called albums, from their colour. The paper is conceived to have been formed of leaves of the papyrus, and not of the skins of animals, used in Asia for the purpose (as stated by Herodotus), nor of parchment, Charta Pergamena, so called from Pergamus in Mysia. M. Egger assumes that wax tablets were used in place of paper on account of their costing less money, though at the present time they would, of course, be by far the dearer material of the two. A family consisting of four adults, could, it is stated, live in Athens on a sum equivalent to £ 20 a year,—and, starting from this data, M. Egger infers that the cost of the wax tablets must, according to the present value of money, have been about 3d. and that of a leaf of papyrus nearly 4s.:—and he writes to M. Didot to inquire whether the papyrus which fetched so exorbitant a price relatively had any qualities to compensate for its dearness. In reply, M. Didot says that the price paid at the period alluded to for a leaf of papyrus corresponds exactly with that of a sheet of vellum at the present day. He agrees with M. Egger, that the paper referred to was the papyrus leaf then an important article of commerce with the Egyptians. The Greeks called it biblos, and the paper made from it chartas, whence the Latin charta, the prepared skins used by the Persians were called dipteri or derris. When the Ptolemies, out of mere literary jealousy, stopped the export of papyrus, in order to deprive Eumenes and Attalus (the king of Pergamus) of the materials for forming books, the latter, whose collection of books already vied with the Library of Alexandria, caused great attention to be paid to the manufacture of skins,—these were called Pergaminon and bembrani, whence membrana. The high price of papyrus had, of course, a great effect upon the cost of books. Plato is said to have paid 100 minæ (equal to about £360.) for the three treatises written by Philolans, the Pythagorean philosopher,—and Aristotle paid three talents (equal to nearly £650.) for a few volumes which had belonged to Spensippus, a disciple of Plato. As the papyrus was of a spongy texture, and the ink ran into it and made the writing difficult to read, the ancients had a plan of sticking two leaves together cross wise as regards the fibres. This however, only produced a partial cure, and experiments were made in applying a coating of size to fill up the pores. A man named Philtotecis at length invented a paste of starch and vinegar, which was looked upon as so important a discovery that the Athenians erected a statue in his honour. It is stated as a remarkable fact that, although the papyrus plant was used so extensively by the Egyptians, who constructed boats and covered houses with the stems, made sails from the bark, fuel of the roots, and clothing and ropes from the fibres, not a single specimen of the plant is now to be found in that country. M. de Sauley states, however, that it may be found in great abundance on the banks of a rivulet in Judæa, between Jaffa and Kaisarieh. When the Arabs began to make paper from the cotton, called charta Damascena, from the original place of manufacture, papyrus began to decline in value,—still the competition between the two articles was maintained with vigour until the application of waste flax and the making of paper was discovered in the twelfth century. The last named, however, themselves doomed to be superseded by the application of rags to the manufacture of paper. London *Athenæum*, May 1857.

(6053) PAPYRUS PANGOREI, Syn CYPERUS TEGETUM.

Madoorkati, HIND.

The Papyrus Pangorei is a sedge, extremely common about Calcutta and is very extensively employed in Bengal for making the elegant shining useful mats for which the Capital of India is famous, and which are frequently imported into Europe. Strips of this sedge are suited for platting.—*Eng. Cyc.*

(6054) PARAS NATH, a mountain in Behar of great sanctity: it is the eastern, as Mount Aboo is the Western Metropolis of Jain worship. —*Hooker. Him. Jour. Vol.* 1, *p.* 18.

(6055) PARATROPIA. PARATROPIA DIGITATA. PARATROPIA VENULOSA. The Karens make an infusion of the leaves of a species of paratropia, a plant of the ivy family, which they use for many internal diseases.—*Mason.*

(6056) PARCHMENT. Consists of the skins of sheep and goats, prepared in such a manner, as to render them suitable for being written upon. It is chiefly employed for charters and other writings where great durability is desirable. —*Faulkner.* Parchment, the skin of an animal prepared for writing on. The name is from the Latin *Pergamena*, from *Pergamus*, the reputed place of its invention. Eumenes II. king of that place (who reigned B. C. 197—159), has the honour of the invention, he being stimulated thereto by the prohibition of the export of papyrus from Egypt. Some authorities consider Eumenes to have been only an improver of the art of preparing skins for writing on, which Herodotus says were commonly used for that purpose in his time; and it is even asserted that the word *pergamena* was not used until several centuries after the death of Eumenes. According to Mabillon, the first writer who uses the term is Tatto, a monk of the fourth century; before his time, the word *membrana* was employed, as in the Greek Testament, 2 Tim. iv. 13.—*Tomlinson.*

(6057) PARCUTILLE, the Tamil name of a Ceylon tree, which grows to about twenty-four inches in diameter, and fifteen feet in height. It is used by the natives in boats, houses, and other works: it is not of great value.—*Edge, Ceylon.*

(6058) PARDANTHUS CHINENSIS. TIGER LILY. A showy yellow and orange flower, whose petals are spotted like a leopard's skin, and belonging to the iris tribe, is very commonly cultivated by the Burmese as well as by Europeans. —*Mason.*

(6059) PAREIRA BRAVA, VELVET LEAF.

Grieswurzel. GER.

A medicinal root, procured from the *Cissampelos Pareira*, a native of the West Indies and South America.—*Faulkner.* Dr. O'Shaughnessy writing on the *Pareira brava*, or wild vine, says Dr. Roxburgh, Fl. Indica, vol. iii. p. 848, describes six species of cissampelos, viz.

(6060) *C. Glabra*, (*vern.* Peer grug,) a native of Sylhet, root acrid and used in medicine by the natives.

(6061) *C. hexandra*, (*vern.* Neemooka,) a native of Bengal.

(6062) *C. convolvulacea*, a native of Coromandel and Malabar.

(6063) *C. Caapeba*, from the Moluccas.

(6064) *C. hernandifolia*, a native of Chittagong.

(6065) *C. tetrandra*, brought from Amboyna. The C. glabra, hexandra, hernandifolia, and convolvulaca, natives of the Peninsula, are all referred by Wight and Arnot to the same species, which differs from C. Pareira chiefly in the form of the sepals, and the length of the staminal columns. We have used the Neemooka of Bengal with decided advantage under the same circumstances as the *Pareira brava* would be employed in. With this and the Menispermum cordifolium we are but little dependent on other countries for the valuable remedy so justly lauded by Brodie and others. —*O'Shaughnessy, page* 200.

(6066) PARIDÆ. A natural family of Perching Birds (Insessores.)—*Eng. Cyc.*

(6067) *Parus xanthogenys*, has the head with a full crest of black feathers; occiput, supercilliary stripe, and cheeks, yellow; ear-coverts black; back olive; wings and tail black, the former spotted, and the latter tipped with white; a broad black line passing down the throat, and extending along the middle of the abdomen; sides of the chest and flanks pale-yellow; bill and feet black; size rather less than that of the Greater Tit, *P. Major*. (Gould). This bird is a native of the Himalaya Mountains. —*Eng. Cyc.*

(6068) PARINARIUM EXCELSUM. POMACEA. A large tree brought to Bombay from Goa: the fruit, which ripens in December and January, resembles a coarse plum, and is held in much estimation.—*Riddell.*

(6069) PARIS, a genus of Plants belonging to the natural order *Asparageæ*. It has a patent horizontal perianth, 8-parted to the base, the four inner parts, or corolla, narrower than the others. There are 8 stamens, the anthers fixed to the middle of a subulate filament. The styles are 4 in number, the berry 4-celled, the cells with from 4 to 8 seeds.—*Eng. Cyc.*

(6070) PARIS QUADRIFOLIA, Herb-Paris, the only British species, has usually four leaves in a whorl, a stem about a foot high springing from the extremity of a long rhizoma, usually with four, occasionally from three to six leaves at its summit. The flowers are solitary and terminal, the sepals lanceolate, the petals subulate. It

has no root-leaves, and is found in damp woods in England. It is considered to be a narcotico-acrid poison.—*Eng. Cyc.*

(6071) PARITIUM MACROPHYLLUM. AND P. TILIACEUM, the bet-mwœ-shaw of the Burmese, furnishes that nation with a material for ropes. Another species, the P. tiliaceum is the Burm, Gyeé-nya-shaw.—*Mason.* Captain Benson exhibited fibres of Paritium macrophyllum, Nos. 8720 and Urena lobata (both malvaceous plants) from Moulmein. These samples possess much merit and the former especially so, being long, soft, pliant and strong, color brown.—*M. E. Juries Reports.*

(6072) PARITIUM TILIACEUM. HIBISCUS. TILIACEUS. Tortuous hibiscus. The banks of our tide-water streams are often damasked with the changeable red and yellow flowers of this large luxuriant bush, whose crooked wandering branches, crossed and locked with each other, spread along the ground heaping the earth with its evergreen foliage.—*Mason.*

(6073) PARKIA, a genus of Plants belonging to the natural order *Leguminosæ* and the tribe *Mimoseæ*. It was named by Mr. Brown in honour of the great African traveller Mungo Park. The genus contains only a few unarmed trees, which are found on the west coast of Africa, the peninsula of India, Silhet, and in the Islands to the eastward of the Bay of Bengal. *Parkia* is distinguished among the Mimosa-like *Leguminosæ* by the tubular 5-cleft calyx and the corolla with 5-distinct petals having a more or less imbricate æstivation; stamens 10, hypogynous, monadelphous. Legume many-seeded, 2-valved, with a farinaceous pulp around and between the seeds. Inflorescence an axillary peduncled and club-shaped spike.—*Eng Cyc.*

(6074) PARKIA AFRICANA is the Nitta, or Doura-Tree of Soudan. The farinaceous matter surrounding the seeds is eaten, and also made into a pleasant drink when steeped in water. The seeds are roasted as coffee is with us, then bruised and allowed to ferment in water. When they begin to become putrid, they are well washed and pounded, and the powder is made into cakes resembling chocolate, which form an excellent sauce for all kinds of meat. (Brown, in Denham.) A species of this genus, the *Mimosa pedunculata* of Roxburgh, is said by him to be similarly valued by the Malays, that is, they eat, the mealy matter which surrounds the seeds, as well as the seeds themselves, which are said to taste like garlic.—*Eng Cyc.*

(6075) PARKIA BIGLANDULOSA. MIMOSEÆ.

Chendoo Phool, HIND.

A very elegant tree; the flower-buds resemble balls of red velvet, legumes filled with a farinaceous edible pulp.—*Riddell.* A very elegant tree of large size, introduced from Africa, the legumes are filled with a farinaceous pulp, the wood is hard and promising, surrounded by an astringent bark. A watery extract has been prepared, but the value of which for tanning purposes has yet to be tested. A supply of timber is not yet procurable. Hort. garden 24.—*M. E. J. R.* The sweet and farinaceous pulp within the pods is highly esteemed and made into sweetmeats. The natives also make a pleasant drink by diffusing the farina through water. This tree has now been introduced, for many years, into some of the Gardens about Madras; the farina is a new article of food in this Presidency and deserves attention.—*M. E J. R.*

(6076) PARKIA SUBGLOBOSA, sweet, farina is prepared from the pods, and used in making sweetmeats—*Eng. Cyc.*

(6077) PARKINSONIA, a genus of Plants belonging to the natural order *Leguminosæ*.—*Eng. Cyc.*

(6078) PARKINSONIA ACULEATA, the Barbadoes Flower-Fence, is a well known West Indian shrub, very generally employed in such climates as an ornamental plant, and especially for the construction of hedges, for which its strong spines render it well adapted. It has long pinnated leaves, with a winged petiole, and grows as much as 12 or 15 feet high. The flowers are large, yellow, very numerous, and a little variegated with red spots, and are succeeded by long narrow knotted pods. When in flower it is said to be one of the most splendid objects in the vegetable kingdom.—*Eng. Cyc.* This small graceful tree, with pretty yellow flowers in loose pendulous racemes, grows readily from seed, and is well adapted for hedge rows, the stem from which the leaves spring is capable of being converted into a white fibre, and might be used for paper making.—*Riddell.* Though this is an American plant, it may, like the Agave, be enumerated among Indian products, because it may now be met with as one of the most common trees in villages and cantonments, flourishing with less care than any other. Some of its fibre, of a beautiful white colour, was sent to the Exhibition of 1851, as a material for paper-making, and which could probably be afforded at a cheap rate, from the cuttings of the shrubs of this plant. It, however, has been considered in this country as wanting in strength. It might, nevertheless, be found useful in mixing with other fibrous substances, and beaten up into half-stuff.—*Royle, Fib. Pl. p.* 298.

(6079) PARSLEY. Apium Petroselinum. A well known seasoning herb, used in soups, garnishing, &c., grows well during the cold months, requires a free rich soil, and planted on a bed raised 6 inches above the surface level, raised from seed.—*Jaffrey.* Is cultivated from seed: may be sown in beds or rows, where it is to remain. The plants, when about two or three in-

ches high, should be thinned, and a space of at least a foot left between each. It will, if watered and taken care of, continue all the year round. A good plan is occasionally to cut down the leaves to within four inches of the root, as it makes the parsley throw out young and fresh leaves. It bears transplanting well. Always give the preference to Europe seed. The common parsley of the country is very insipid. The roots of parsley are much used in French cookery.—*Jaffrey.*

(6080) PARSNIP. This vegetable is very difficult to rear, as it does not often happen that the seeds come up; they should be sown broadcast in beds of a rich soil, and the plants, when of a sufficient size, carefully thinned, leaving a space of one foot between each plant and removing all weeds. They may be transplanted, but it must be done with the same care as recommended for beet-root. The proper time for sowing the seed is the latter end of July, and they will come in during March and April. It goes to seed freely, but the roots grown from it were by no means fine the second year.—*Jaffrey.*

(6081) PARTHENOPIDÆ, or *Parthenopians* of Milne-Edwards. This tribe, in the arrangement of M. Milne-Edwards, corresponds nearly to the genus *Parthenope* as established by Fabricius, but the species are separated by Milne-Edwards into the genera *Eumedonus*, *Eurynome*, *Lambrus*, *Parthenope*, and *Cryptopodia*, forming a natural group which, in the opinion of the last-named zoologist, establishes the passage between the Maians [MAIDÆ] and the Cyclometopes. The tribe is widely distributed, and species are found in the English Channel, the Mediterranean Sea, and the Indian Ocean.

Species:

Lenang [illegible]chinatus. It is found on the coasts of quarter, [illegible]ry.

Bengal, s[illegible]*anus*, is found at Pondicherry, Amboyna, &c.

L. serratus. It inhabits the Indian Ocean. —*Eng. Cyc.*

(6082) *Parthenope Horrida*, is a native of the Indian and Atlantic Oceans.

Cryptopodia fornicata. (Edwards.) Inhabits the Indian Ocean.—*Eng. Cyc.*

(6083) PASPALUM (from one of the Greek names for Millet), a genus of Grasses, which, like some species of *Panicum*, forms one of the small grains cultivated in tropical countries as food for the poorer classes of the community. The genus is characterised in habit by having a continuous spiked rachis, on one side of which the spikelets are attached. The glume is 2-valved, 1-flowered, closely pressed to the two plane convex paleæ. Seed adhering to the paleæ.—*Eng. Cyc.* One or more species of paspalum are products of Tenasserim fields.—*Mason.*

(6084) PASPALUM FRUMENTACEUM. Linn.

Warroogoo. TAM.	Kodow, HIND.
Kodorow, DUK.	Khodra, GUZ.
Arikehloo, TEL.	Kodravaha, SANS.
Harakah, CAN.	

This small, valuable grain tastes something like rice, and is prepared in the same way by the Indians. There is a variety of it, called in Tamul Serrookoo Warroogoo and in Teloogoo, Tikka Arikehloo, which, if not dressed in a particular manner, is said to produce vertigo, nausea and other unpleasant symptoms. Dr. D. White of Bombay, writes that this variety is called in Guzerattie, Menya, which he naturally supposes is taken from the Sanscrit word Mana, signifying causing Phrensy.—*Ainslie, p.* 220.

(6085) PASPALUM PILOSUM, Roxb.

Pani Warroogoo, TAM.

This is a grain cultivated in Coimbatore, where it is eaten by the poor.—*Ainslie, p.* 220.

(6086) PASPALUM. SCROBICULATUM, the Koda of the natives of India, is cultivated over almost all parts of India. It delights in a light, dry, loose soil, but will grow in a very barren one. The seed is an article of diet with the Hindoos, particularly with those who inhabit the mountainous parts of the peninsula, as well as in the most northern parts of the country, or where the soil is barren and unsuited to the cultivation of those grains which are more beneficial. Dr. Roxburgh states that the boiled grain is as palatable as rice. He distinguishes from this another species, which Linnæus called *Paspalum Kora*, but it appears to be only a variety growing in moist situations. Both species are much relished by cattle either in a green or dry state.—*Eng. Cyc.*

(6087) PASSIFLORA, a genus of twining Plants, the species of which are called Passion Flowers. This name is derived from a fancied resemblance between the parts of their flower and the emblems of Our Saviour's crucifixion. In the five anthers the Spanish monks saw his wounds, in the triple style the three nails by which he was fixed to the cross, and in the column on which the ovary is elevated the pillar to which he was bound; a number of fleshy threads which spread from a cup within the flower were finally likened to the crown of thorns. "There are cuts," says Sir James Smith, "to be found in some old books, apparently drawn from description, like the hog in armour [illegible] to represent the rhinoceros, [illegible] is made up of the very things [illegible] genus comprehends a large number of [illegible] chiefly found in a wild state [illegible] within or near the tropical parts [illegible] nent. They are all twining [illegible] bling over trees to a considerable length, and [illegible] many cases are most beautiful objects on account

of their large gaily- or richly-coloured flowers. This makes them favourites in gardens, where many are cultivated, particularly the *P. alata*, *P. quadrangularis*, *P. edulis*, *P. cærulea*, *P. racemosa*, *B. Londoni*, *P. onychina*, *P. palmata*, and *P. filamentosa*, all of which are strikingly handsome. It is however chiefly for their fruit that they are valued in the countries where they grow wild, in consequence of the pulp which envelopes the seeds being cool and refreshing, with something of a fragrant bouquet. Under the name of Granadilla, the *P. quadrangularis* is well known in Brazil, where its fruit is as large as a child's head; the Water-Lemon of the West Indies is the produce of *P. laurifolia*; *P. maliformis* bears what is called the Sweet Calabash; and the pleasant pulp of *P. edulis* furnishes the confectioner with the most delicate material for the flavouring of ices. Many however are of no value for their fruit, and some are actually fœtid.—*Eng. Cyc* The greater number do well on the plains, they require abundance of water. Not at all adapted for pot culture, easily propagated by cuttings during the rains under glass; some of the common varieties can be propagated in the open air during that season, require a well manured soil. Natives of the tropics, many of which have been hybridized.—*Jaffrey.*

(6088) PASSIFLORA. PASSIFLORACEÆ.—Passion Flower. Passiflora Alata.—These ornamental climbers, are common in most parts of India, the species are numerous, being of easy culture. Some of them are fruit bearing, as the P. edulis and P. laurifolia, the latter is known from its dark shining leaves. There are several wild varieties.—*Riddell.*

(6089) PASSIFLORA FŒTIDA. A species of passion flower with fœtid flowers, but very elegant moss-like involucres, though rarely noticed in gardens, may be often seen creeping over the hedges in Maulmain like an indigenous plant.—*Mason.*

(6090) PASSIFLORA LAURIFOLIA. LAUREL-LEAVED PASSION FLOWER. Numerous species of passion flower are seen wandering over the arbors and trellises of our sunny greens, but none exceed in beauty, and fragrance the laurel-leaved passion flower, called in the West Indies, water lemon vine, which appears to have been the first of the tribe introduced into Burmah.—*Mason.*

(6091) PASSIFLORA LESCHENAULTII.

(6092) PASSIFLORA QUADRANGULARIS. GRANADILLA. This luxuriant exotic from the Jamaica passion flowers, flourishes well on the Tenasserim Coast, and is very prolific. The smooth oblong fruit grows nearly as large as a cucumber, and contains a succulent pulp, which makes a cooling delicious dish, and when prepared in tarts, can scarcely be distinguished from green apple. The Rev. Mr. Bennett of Tavoy, has recently introduced it among the Karens, by whom it is highly esteemed, and much sought for. It will no doubt soon be generally diffused through the Provinces, as it possesses all the attractive qualities of fine fruit, handsome fragrant blossoms, and when trailed over an arbor, a rich passing shade.—*Mason.*

(6093) PASTINACA (from *Pastinum*, the Latin name for a two-pronged fork), a genus of Plants belonging to the natural order *Umbelliferæ* and the tribe *Peucedaneæ*.—*Eng. Cyc.* Wight gives pastinaca hookeriana, 1010; rigens, 1009; Sprengeliana, 1008;

(6094) PASTINACA SATIVA, the Parsnip, has an angular furrowed stem; pinnate leaves, downy beneath: ovate-oblong leaflets, crenate, serrate, often with a lateral lobe at the base. It is extensively cultivated in Guernsey and Jersey as fodder for cattle In the north of Ireland parsnips are used in the composition of a kind of beer brewed with hops. Wine and ardent spirits are likewise made from the roots.—*Eng, Cyc.*

(6095) PASTINACA SEKAKUL is another edible species of this genus, and is a native of Syria and Egypt. It has a gray root; a terete downy branched stem; pinnate downy leaves; pinnatifid cut leaflets, blunt and unequally toothed. —*Eng. Cyc.* Pastinaca Secacul is the Shakakel misree (Sium Sisarum, Ainslie) so much used by Eastern doctors, and not without reason, for this root is a very efficacious medicine. Dr. Royle thought it came from Cashmere to Hindostan, but I heard that it is imported from Egypt; and hence, probably it is called the Egyptian (misree)—*Honigberger, p.* 322.

(6096) PATA. Leaf of [illegible] whit. —*Rheede Malabar.* 10. p. 79. —*Rottlera tinctoria*.—*Ben. Ph.* 219.

(6097) PATA ROC[illegible] of Pondicher[illegible] long Indian of Sida Acuta.—*Ben.* [illegible] *L. longim*[illegible] met with

(6098) PATCHOULY OR PUCHAPAT, POGOSTEMON PATCHOULI, is an article well known in Bengal, and though its source was long doubtful, it is found in every bazar almost throughout India, and seems to grow abundantly as well as on the opposite shore of the Malay Peninsula, in province Wellesley, in India, and in a perfect wild state at Penang. M. de Hugel found it growing wild near Canton. Dr. Wallich says that it obviously belongs to the family of Labiatæ, and remarks that "whether *Marrubium Odorotissimum*, *Betonicoe folio*. J. Burm. Thesaur. Zeylon, p. 553, tab. 71, fig 1, (Marrubium Indicum, N. L. Burman. Flor. Ind. p. 127), be our plant or not, it is difficult to say"; but he thinks that there is at least a considerable affinity between them. Viney, in the "French Journal of Pharmacy," suggests that it is the Plectranthus graveolens of R. Brown. The name of the plant however,

is the *Pogostemon Patchouli*. The odour of the dried plant is strong and peculiar, and to some persons not agreeable, the dried tops imported into England are a foot or more in length. In Europe it is principally used for perfumery purposes, it being a favorite with the French, who import it largely from Bourbon. They were led to use it because, a few years ago, real Indian shawls bore an extravagant price, and, purchasers distinguished them by the odour of Patchouly with which they were perfumed, and on discovering this secret, the French manufacturers got in this way of importing the plant to perfume articles of their own make, and thus palm off home spun shawls for real Indian. The Arabs use and export it more than any other nation. Their annual pilgrim ship takes up an immense quantity of the leaf, they use it principally for stuffing matrasses and pillows, and assert, that it is very efficacious in preventing contagion and prolonging life. The characteristic smell of Chinese and Indian Ink, is owing to an admixture of this plant on its manufacture. Some people put the dry leaves in a muslin bag, and thus use it as we do lavender, for scenting drawers in which linen is kept; and this is the best way to use it, as this odour, like musk, is most agreeable when very dilute. In India it is used as an ingredient in Goorakoo tobacco for smoking and for scenting the hair of women. It requires no sort of preparation, being simply gathered and dried in the sun: too much drying, however, is hurtful, inasmuch as it renders the leaf liable to crumble to dust in packing and stowing on board. By distillation it yields a volatile oil, on which the odour and remarkable properties depend. This oil is in common use in India for imparting the peculiar fragrance to clothes: among the superior classes of natives in Penang it sells at the rate of a dollar and a quarter, to a dollar and a half, per pekul. In Bengal, some which was imported from Penang several years ago, sold at 11 rupees eight annas per maund. Later investments have sold at a much lower rate.

(6099) PATELLIDÆ, a family of Prosobranchiate Gasteropodus *Mollusca*. The shell is conical with the apex turned forwards; the muscular impression horse-shoe-shaped, open in front. The genera belonging to this family are *Patella*, *Acmæa*, *Gadinia*, and *Siphonaria*. *M.* De Blainville referred these Molluscs to his order *Cervicobranchiata*, and Cuvier to his order *Cyclobranchiata*. Ex. *P. compressa*. Inhabits the Indian Seas. Lam. The *Patellæ* are very widely spread, and few seas are without them. None however appear to have been observed in the Arctic Seas, either by Captain Parry (1819) or Captain Ross. The larger species are found principallly in warm climates.—*Eng. Cyc.*

(6100) PA-THA-YOU-SHA, a bast of Arracan strips seven feet in length; fine in texture, light coloured: formed of several easily diffusible layers: the outer layers, rather dense and compact, and the inner cancellar. A musa species? —*Royle.*

(6101) PATTUNGA CUTTAY, VATTUNGA CUTTAY.

Vattunga Cuttay, TAM.

This is a Tamul name of a wood which is used for dying cotton cloth, mats &c. of a bright red colour. The dye is fixed by means of the Chebulic Myrobalan and alum.—*Ains. Mat. Med. p.* 204.

(6102) PATOO OR ASTA, is a bast from Beerbhoom, is like the Putwa from Bhagulpore.—*Royle.*

(6103) PAUCHONTEE TREE. Isonandra Polyandra. In 1855, General Cullen forwarded a drawing and description of a large forest tree, abounding at the foot of the Ghauts N. E. of Trevandrum. The plant delineated, was evidently one of the Sapotaceæ and the Malayalim name is "pauchonthee," and the product, of which a good sample was forwarded, on examination bears a strong resemblance to gutta percha, both in external appearance and mechanical properties. At the same time Lieutenant Col. F. Cotton, Engineers, forwarded from the Neilgherries a small sample of a product similar to gutta percha in its smell, general appearance and fracture. No drawing of the tree was submitted, but a few leaves which surrounded the exudation, very closely resembled the real *Isonandra gutta*. The trees are said to be very large and numerous in the forest.—*M. E. J. R.* It seems to be a practice with the people who collect the Gutta Percha of the Malayan peninsula, to mix the juices of several other species of Isonandra with that of the true Isonandra Gutta. And though this mixture confessedly depreciates the value of the gum, as the products of the several species have, to some extent, similar properties, the adulteration allows the commercial article to be applied to many purposes in the arts, which the higher price and the scarcity of the true gum gutta would exclude it from. It was therefore with pleasure that we perused an interesting communication from Mr. Lascelles along with one from a former correspondent, Wynaadensis: for the latter confirms what had previously been surmised, the existence on the Koondahs of several species, five if not six, of this genus of useful plants. These correspondents are both inclined to believe that the true Isonandra Gutta grows in Wynaad, but we do not think that this opinion is entertained by those best capable of judging. Mr. Lascelles mentions that the scientific men there, have had some difficulty in defining the species of the tree recently discovered. Mr. Lascelles seemed too hastily to decide against General Cullen's discovery of the Pauchountee tree being the Isonandra Polyandra. For if Wynaadensis' present report be

correct, that there are "*five if not six*" species of Isonandra on the Koondahs, the one sent by General Cullen may really be what it was named, although Mr. Jaffrey confined his observations to stating that the tree examined by him was the Isonandra Polyandra of Wight's Icones, thus evidently leaving it to Dr. Wight to settle the correctness of his own nomenclature. On the matter of priority of discovery, it is evident that, as with many other objects, the existence on the Western coast of India, of a Gutta Percha seems to have become known to General Cullen and Mr. Lascelles about the same time, but the former, by figuring the plant in February 1855, and sending specimens of its flower, its fruit, its leaves, and its gum, gave that prominent publicity to it without which an article may as well remain undiscovered. We formerly made some observations on the wood of this tree. We learn that the wood of the *Pauchountee* tree is in gravity not less than 55 lbs. the cubic foot, and that a bar of one inch square, with 18 inches clear of the supports, at each end, broke with a long fibrous fracture, after a weight of 440 lbs. had been imposed: —though not till this weight had for some minutes been suspended from the bar. This tenacity, we believe, is as high if not higher than that of teak. The above experiment has been made by General Cullen, who has likewise ascertained that the Pauchountee tree when tapped, two taps at every three feet, from the base to sixty feet high, or 40 taps in all, yielded in twelve hours about eight pints or pounds of the sap. This abundant flow supports Mr. Lascelles' opinion that Malabar alone will supply Gutta Percha to the world for the next quarter century, and we trust therefore that the orders recently issued by Government to protect the trees from wasteful destruction have been at once acted upon by the several authorities of the districts there.—See Report of the Madras Museum of 1856; by the Author

(6104) PAVETTA BREVIFLORA 1635; Brunonis, 1065; Indica, 148; Rothiana, 1065.

(6105) PAVETTA INDICA. Lin.

Pavatty kai, TAM.	Pappana, SANS.
Paputta kaia. TEL.	

An ornamental shrub 4 or 5 feet high with white flowers, timber very small.—*M. E. J. R.* The berries are considered amongst the Kais or garden stuffs of the Tamools: they are not however very palatable.—*Ainslie, p.* 243.

(6106) PAVETTA TOMENTOSA. PAVETTA. An indigenous species of pavetta, with flowers resembling a white ixora is found at Tavoy.—*Mason.*

(6107) PAVIA, a small division of the natural order *Æsculaceæ*, differing from *Æsculus* itself in little except its converging petals and spineless fruit. It consists of small trees or bushes with yellow or red flowers, inhabiting North America, where they are called Buck's-Eye Chestnuts. They are often cultivated in shrubberies under the name of the Yellow or Scarlet Horse-Chestnut. Two species, *P. Indica* and *P. Punduana*, have also been found in the colder parts of India, but they have not been introduced into our gardens.

(6108) PAVONIA ODORATA. Wild.

Peramootie poo, TAM.	Bulla, SANS.
Mootopolaghum, TEL.	

It is this flower to which Mr. Moor alludes in his "Hindoo Pantheon," under the name of Bela, (p. 450) and which he erroneously supposes to be that of a species of Jasmine. It is a most delightful smelling flower, and is one of those with which the arrows of Kama, the god of love, are said to be tipped.—*Ains. Mat. Med. p.* 163.

(6109) PAVONIDÆ. a family of Rasorial Birds, to which the Peacock belongs. The genus *Pavo* of Linnæus stands next to *Didus* [DODO] in the 'Systema Naturæ,' and is immediately succeeded by *Meleagris*, which is followed by *Crax*, *Phasianus*, *Numida*, and *Tetrao*. Cuvier makes his Paons consist of the true Peacocks (*Pavo*, Linn.) and *Lophophorus*. This group is followed by the Dindons *Meleagris*, Linn.) the Peintades (*Numida*, Linn); and the Faisans (*Phasianus*, Linn., including the Cocks and Hens—*Gallus*, Briss; the true Pheasants (*Phasianus Colchicus*, &c. including *Argus*, Temm.); the Crested Pheasants (Houppiferes, Temm., *Phasianus ignitus*, &c.); the Tragopan, (*Tragopan Satyrus*, &c.); and *Cryptonyx*. The *Tetraonidæ* immediately follow. Mr. Swainson makes the *Pavonidæ*, the first family of the order *Rasores*, according to his arrangement, consist of the genus *Pavo*, with the sub-genera *Argus*, *Polyplectron*, and *Meleagris*; the genus *Phasianus*, with the sub-genera *Phasianus*, *Nycthemerus*, and *Ceriornis* (*Tragopan*); the genus *Gallus*; the genus *Lophophorus*; and the genus *Numida*. In this work, *Phasianus*, with its sub-genera, *Tragopan*, *Gallus*, and *Euplocamus*, are treated of under the title PHASIANIDÆ. Two species only of this magnificent genus are recorded, *P. cristatus* and *P. Japonensis.*—*Eng. Cyc.*

(6110) PAVO CRISTATUS.

Mohr, HIND.-MALL.	Nemelay, TEL.
Aumail, TAM.	

The Common Peacock. This is the Ταὼς & Ταὼς and of the Greeks; *Pavus* and *Pavo* of the Romans; Pavon and Pavone of the Italians; Pavon of the Spanish; Paon of the French; and Pfau of the Germans. The head is surmounted by an aigrette of 24 upright feathers. In the male the tail-coverts consist of feathers with loose barbs and of unequal size, the upper one shortest, each terminated by numerous eyes or circlets of a metallic iridescent brilliancy:

these the bird has the power of erecting into a circle or wheel, which presents, when the sun shines on it, an object of dazzling splendour which sets all description at defiance. The female has the aigrette, but has not the splendid ornament with which the male is gifted; her colours generally are sombre. This species is spread over the north of India and the islands of Malaisia in its natural state. It is the Mohr of the Mahrattas, according to Colonel Skyes, who describes the wild bird as abundant in the dense woods of the Ghauts; it is readily domesticated, and many Hindoo temples in the Dukhun (Deccan) have, he tells us, considerable flocks of them. On a comparison with the bird as domesticated in Europe, the latter, both male and female, was found by the Colonel to be identical with the wild bird of India. Colonel Williamson, in his account of peacock-shooting, states that he had seen about the passes in the Jungletery district surprising quantities of wild pea-fowls. "Whole woods were covered with their beautiful plumage, to which the rising sun imparted additional brilliancy. Small patches of plain among the long grass, most of them cultivated, and with mustard, then in bloom, which induced the birds to feed, increased the beauty of the scene. "I speak within bounds," continues Colonel Williamson, "when I assert that there could not be less than twelve or fifteen hundred pea-fowls, of various sizes, within sight of the spot where I stood for near an hour."—*Eng. Cyc.*

(6111) PAVO JAPONENSIS. Aldrov. (*P. Javanicus*, Horsfield.) Mr. Bennett, who had an opportunity of examining two living birds in the garden of the Zoological Society of London, in addition to stuffed specimens, gives the following accurate description of this species. Prevailing tints blue and green, varying in intensity and mutually changing into each other according as the light falls more or less directly upon them. In size and proportions the two species are nearly similar, but the crest of *P. Javanicus* is twice as long as that of *P. cristatus*, and the feathers of which it is composed are regularly barbed from the base upwards in the adult bird, and of equal breadth throughout. Head and crest interchangeably blue and green. A naked space on the cheeks, including the eyes and ears, is coloured of a light yellow behind, and bluish-green towards its fore part. The feathers of the neck and breast, which are broad, short, rounded, and imbricated like the scales of a fish, are at their base of the same brilliant hue as the head, and have a broad, lighter, somewhat metallic margin; those of the back have still more of the metallic lustre. The wing-coverts are of the general hue, with a deeper tinge of blue; the primary quill-feathers are light chestnut. The tail-feathers and their coverts (train) are of a splendid metallic brown, changing into green; their barbs are extremely long, loose, silky, and somewhat decomposed; and the latter are almost all terminated by ocellated spots similar to those which mark the tail (train) of the common species, and of nearly the same size. As in it, they are of beautiful deep purple in the centre, which is about the size of a shilling; this is surrounded by a band of green, becoming narrow behind, but widening in front, and filling up a kind of notch that occurs in the blue; then comes a broad brownish band; and, lastly, a narrow black ring, edged with chestnut, all beautifully metallic, or rather representing the hues of various precious stones when viewed in certain lights. Bill of a grayish horn-colour, rather longer and more slender than in the common species; iris deep hazel. Legs strong, naked, reticulated, dusky black; spurs large and of the same hue. ('Gardens and Menagerie of the Zoological Society.') The bird above described is the *Pavo muticus* of Linnæus, who, as the name implies, described it as being devoid of spurs, relying probably on Aldrovandus, whom he quotes, and who figures it without spurs, describing it under the name of *Pavo Japonensis*. It is the Japan Peacock of Latham, the *Pavo spicifernus* of Vieillot, the *Pavo Aldrovandi* of Wilson, and *Pavo Javanicus* of Dr. Horsfield, who saw it in Java. Of these names, that of Aldrovandus has the priority; then comes that of Linnæus, which may mislead; then that of Horsfield; then that of Vieillot. We do not see anything objectionable in the name given by Aldrovandus, and therefore we have retained it.

(6112) *Meleagris* (Linn).—The Meleagris of the ancients was not a turkey, but a guinea-fowl. (Linnæus however having given this as the generic name for the Turkeys, which were not known to the ancients, ornithologists have continued it.) Nor is this now of much consequence, certainly not of sufficient importance to change the name; for notwithstanding the confusion and doubt thrown over the subject by the learned discussions of the earlier modern ornithologists, it is generally known and satisfactorily proved that the Turkeys were only known to Europeans after the discovery of America, from which one species has been spread in a domesticated state over the greatest part of the civilised globe It has the following generic characters:—The bill rather short, strong, curved, convex, vaulted, its base furnished with a naked skin; a fleshy caruncle surmounting the bill of an erectile nature and conical form. Head and neck surrounded with a wrinkled mammillated skin, hanging loose like a dewlap as far as the upper part of the breast. Hind toe touching the ground. Two species are known: one, *M. Gallopavo*, the original stock from which the domesticated turkey is derived; the other, *M. ocellata*, a much more beautifully plumaged bird, did not exhibit in the only known specimen any trace of the

tuft of hair on the breast. That character therefore is omitted above; but it is not certain that the last-mentioned species is entirely without the tuft, for the plumage of the specimen was damaged.

(6113) *M. Gallopavo.* This is the *M. occidentalis* of Bitram; *M. fera* of Vieillot; Gallo d' India, Gallinaccio (male), Gallina d'India (female) of the Italians; Coq d'Inde and Dindon, Dinde (female), of the French; Indianische Hahn of the Germans; Wild Turkey and Domestic Turkey of the British and Anglo-Americans.

(6114) *Polyplectron* (Temm). This beautiful form was raised to the rank of a genus by M. Temminck, who established it upon the bird which was named *Pavo Tibetanus* by Brisson, the Chinese Peacock-Pheasant by Edwards, *Pavo bicalcaratus* by Linnæus, and L'Eperronier by Buffon. Cuvier placed it among the Peacocks, properly so called, but other species have been since discovered, which, throwing further light upon the modifications of form, well justify its genuine separation. It is the *Diplectron* of Vieillot. —*Eng. Cyc.*

(6115) *Polyplectrum Emphanum.* Male, Length about 19 inches. Forehead and crown ornamented with a crest of long, narrow, loose feathers, which together with the plumage of the neck and breast, are rich bluish-black with metallic reflections. Towards the end of each feather there is a blackish bar. This beautiful and ample tail is supposed not to be erectile, but to be capable of very wide expansion. This is the Eperonier a Toupet of M. Temminck; the Crested Polyplectron. Probably inhabits Sunda and the Molucca Isles.—*Eng. Cyc.*

(6116) *Polyplectron Tibetanum.* This is the *Pavo Tibetanus* of Brisson and Gmelin, the Chinquis of Buffon, the Thibet Peacock of Latham, the Peacock Pheasant of Edwards, and the Eperronier Chinquis, Polyplectron Chinquis of Temminck. It is supposed to be a native of the mountain chain which separates Hindustan from Tibet. In the *Polyplectron Chalcurum* the plumage is comparatively sombre. The ocellated spots on the wings and tail are absent, and the latter, instead of being rounded, has a more elongated pheasant-like form, approaching to that of *Argus.* The beautiful birds above briefly noticed, and inhabiting the Indian Islands or China, are described as being almost as hardy as the Peacock, and there is little doubt that they might be domesticated in England. The Tibetian Polyplectron is procured for the aviaries of the wealthy Chinese, and M. Temminck's drawing was taken from a bird that had lived for five or six years in an aviary at the Hague.

(6117) ARGUS (Temm.). The only species known is *Argus giganteus.* This bird is remarkable for the beauty of its plumage. The wings, the secondaries of which are three times as long as the primary quills, are painted and ocellated in a manner that defies description. This bird is the beautiful Chinese Pheasant described in 'Phil. Trans.,' vol. 55, p. 88; L'Argus ou Luen of Buffon; Argus Pheasant, *Phasianus Argus* of Latham; L'Argus, *Argus giganteus* of Temminck. The unwieldy size of the secondaries forms an impediment to the bird in its progress through the air, but they assist its pace when running, which it does swiftly with their aid. Its flight, when it does rise on the wing, is heavy and short. When the bird is at rest or unexcited, the beauty spots on the secondaries are hardly visible; but when showing himself off in the presence of his females, the wings of the *Argus* are expanded, and trailed upon the ground to display their beauties; and at this time the tail is comparatively spread, and is raised erect; when at rest it is carried in a line with the body, and with the two long feathers folded together. The rest of its habits are not known, but it is said not to thrive well in confinement. It is a native of Sumatra, and probably other Indian Islands, but principally of Malacca. No proof appears of its having been brought from China and Chinese Tartary, although ornithological writers name those countries as the places of its habitation. The feathers and drawing of the bird described in the 'Phil. Trans.' by G. Edwards were sent from Canton to Dr. Fothergill, and are stated to have come from one of the most northern provinces of China.

(6118) *Lophophorus*, Temm. (*Monaulus* Vieill.)

(6119) *L. Impeyanus* (*L. refulgens*, Temm.; Impeyan Pheasant, *Phasianus Impeyanus*, Lath.) We must refer our readers to the bird itself, or to the excellent figure in Mr Gould's 'Century of Birds from the Himalaya Mountains,' for anything like an adequate idea of the beauty of its tints; for the greater proportion of the plumage is dazzling with changing hues of green, steel-blue, violet, and golden-bronze. The bird looks as if it were principally clothed in a scale-armour of iridescent metal; but the plumage is soft and velvety to the touch. The crest on the head consists of naked-shafted feathers, with an oval or battledore tip of the same quality as the rest of the plumage, and of a metallic green; the centre of the back is pure white; the tail is rounded and bright chestnut. Size of a hen turkey. The principal food of this species consists of bulbous roots, for scooping out which its bill is well adapted. Nothing certain seems to be known of the rests of its habits. It is a native of the mountain ranges of Nepaul and the Himalayas.

(6120) *Numida* (Linn.). The birds known to the ancients under the name of *Meleagrides* and *Gallinæ Numidicæ* belonged to this genus. They are all natives of Africa, living principally on berries, small slugs, &c.

(6121) *N. Meleagris* (the Gallina di Numidia of the Italians; Poulle de la Guinee and Peintade Meleagride of the French; Pintado of the Spanish; Perl Huhn of the Germans; and Pearl Hen, Guinea Hen, and Common Guinea Fowl of the English) is too well known to need description. The bird has been spread very widely, and few poultry-yards are without it. In Jamaica, where they do much mischief to some of the crops, they have resumed their wild habits, and are shot like other game.—*Eng. Cyc.*

(6122) PAYA WOOD. Paya kurra.

(6123) PAYUNG in Malay and Javanese, and Songsong in Javanese only, an umbrella. This is the universal badge of rank from the prince to the humblest office-bearer among the civilised nations of the Malayan Archipelago, and stands instead of the crowns, coronets, stars and ribbons of the nations of Europe. The quality of the party is expressed by its size, colour, or material.—*Crawfurd Dict. p.* 330.

(6124) PEACH, AMYGDALUS PERSICA. Amongst the more important of the acquisitions which, says Fortune, I made in the vicinity of Shanghae, I must not forget to mention a fine and large variety of peach, which comes into the markets there about the middle of August and remains in perfection for about ten days. It is grown in the peach orchards, a few miles to the South of the City; and it is quite a usual thing to see peaches of this variety eleven inches in circumference and twelve ounces in weight. This is probably, what some writers call the Peking peach, about which some exaggerated stories have been told. Trees of the Shanghae variety are now in the garden of the Horticultural Society of London.—*Fortune's Wanderings, p.* 404

(6125) PEACH PALM. (Guilielma speciosa), the "Pupunha, produces an agreeable fruit of a red and yellow colour."—*Seeman.*

(6126) PEACH WOOD, NICARAGUA. An inferior kind of brazil-wood, used to dye a fugitive "fancy red."—*Waterston.*—*Faulkner.*

(6127) PEACOCK, in Malay and Javanese, Marak, and in the polite dialect of the latter, Manura, which is Sanscrit. The bird known by this name is the Pavo muticus of ornithologists, and a distinct species from the Indian one which is that of our poultry-yards. It appears to be confined to Java, Sumatra, and the Malay Peninsula, and has never been domesticated by the natives of the Archipelago.—*Crawfurd Dictionary, page* 330.

(6128) PEAH SAUL OR YEGASEE.

Yegassee, TEL.	Peeah saul, HIND.

Are well-known globular concretions found in several species of shell fish. They consist of alternate concentric layers of membrane and carbonate of lime. The best pearls are of a clear bright whiteness, free from spots or stains, with the surface naturally smooth and glossy. Those of a round form are preferred, but the larger pear-shaped ones are esteemed for earrings. *Seed* pearls are those of the smallest size. The most extensive pearl fisheries are those of the Gulf of Manaar in Ceylon, and Bahreen in the Persian Gulf. Pearls are imported into Bombay from the latter place, and are re-exported to England and China.—*Faulkner.* Pearls are fished up on nearly all parts of the Ceylon coast and are frequently large and beautiful. The Chinese taught the natives their value by offering them very high prices for the finest qualities. The pearl fisheries for which the Island was once famous have very much diminished in their yield. The natives account for the diminution by declaring that the pearl oyster has the power of locomotion and has shifted its former quarters to some new ground not yet discovered. The scarcity is probably owing to the fact that the pearls have been disturbed before they have reached their full development which is said to require a period of seven years. Since that period the proceeds have gradually fallen off until at present they amount to almost nothing. Diving for the pearl-oyster is a favorite occupation among the natives of Ceylon, as a skilful diver can earn ten times the wages of a farm laborer, and the employment is not, as has been stated, unfavorable to health, but on the contrary conducive to strength and vigor of body.—*American Expedition.* Pearls are found in China; and Marco Polo speaks of a salt lake, supposed now to be in Yunan, which produced them in such quantity that the fishery in his day was farmed out and restricted lest they should become too cheap and common, but such is not now the case judging from the numbers annually imported from India. The Quarterly Review speaks of an artificial mode practised by the Chinese of making pearls by dropping a string of small mother-of-pearl beads into the shell which in a year are covered with the pearly crust.—*William's Middle Kingdom, p.* 272.

Pearls, to the amount of £500,000, are annually brought to Canton; *coral* is also a part of cargoes from the Archipelago to China.—*Williams.* Pearls are obtained from a shell-fish, commonly called the pearl oyster. The principal fisheries are on the Coast of Madura, the Strait between Ceylon and the Continent, the Island of Baharen, in the Persian Gulf, and at Hainan, on the Coast of China. The pearl divers pile the shells upon the shore in little pits, and cover

them with sand, till the shell opens, and the fish is destroyed. The pearls are then procured, cleansed, and passed through a kind of sieve, according to their sizes: the smallest are denominated *seed* or *ounce* Pearls, and are of very inferior value. The quality or value of Pearls depends chiefly upon their size and colour. Their true shape is a perfect round. The colour should be a pure white; not dull and lifeless, but clear and brilliant; free from foulness, spot, or stain; surfaces naturally smooth and glossy. The shell, which is the *Mother of Pearl*, is compressed and flat, nearly orbicular; the inside exquisitely polished, and of the whiteness and water of the pearl itself. It has the same lustre on the outside, when the external coats have been removed by aquafortis. It is used (especially by the Chinese and Japanese) in a variety of inlaid works, toys, &c.—*Morrison.* Pearls worth fishing are found in the seas about the Arrow Islands, and in those of the Sulu Archipelago, but none in size or quality to be compared with those of the Manar or Persian gulfs. Mother-of-pearl oysters are found in the same situations and on the coasts of several of the Bisaya islands of the Philippines much more abundantly. From Manilla there are yearly exported about £ 200,000 pounds worth of them. Mr. Windsor Earl has given the following very satisfactory account of the fishing of the Arrow Islands on the coast of New Guinea. "But the great sources of wealth are the pearl and tripang banks, which lie on the eastern side of the group, and are often several miles in width, being intersected by deep channels some of which will admit vessels of burden. The pearl oysters are of several varieties; first, the large oyster with its strong thick shell from six to eight inches in diameter which furnishes the mother of pearl shell of commerce. These are obtained by diving and are highly prized, being nearly always in demand at Singapore for the European and Chinese markets. This oyster produces few real pearls, but gnarled semitransparent excrescences are occasionally found on the surface of the inner shell, which are so highly esteemed by the Chinese that they often fetch enormous prices. The other description is the small semitransparent pearl oyster, having the inner surface of the shell of a bluish tint. The shell is of small value as an article of commerce, but the oyster itself often contains pearls which although individually of no great value, are so numerous, as amply to repay the labour of collection. Pearls of sufficient size to undergo the process of boring are sometimes found, but the greater portion are what go by the name of seed pearls, and are only marketable in China, where they are much valued as a medicine when pounded and mixed with some liquid." Journal of the Indian Archipelago, Vol. iv. p. 490. The names for the pearl in Malay and Javanese, mute, mutya, and mutyara, are all Sanscrit, and I am not aware that in any of the Malayan languages there are native names for it. Occasionally the Persian word lulu is used. The name for the mother of pearl oyster, indung-mutyara, is exactly equivalent to our own, for the Malay word indung signifies mother or matrix. From this we may suppose that both the pearl and mother of-pearl were most probably made known to the Malayan nations by the Hindus. It may be remarked, that the pearl-fishing of the Sulu Islands was certainly carried on before the arrival of Europeans, for they are mentioned by the indefatigable Barbosa. "Going on," says he, "in a northerly direction towards China, there is another island abounding in the necessaries of life called solar (Sulu) inhabited by a gentile people almost white, and in person well made. They have their own proper king and language. In this island is found much gold by washing the soil, and over against it, the people go to fish small pearls, and even find occasonally larger ones, fine as to colour and roundness." Ramusio, Vol. i.—*Crawfurd, Dictionary page* 330.—*Eng. Cyc.* The pearl is a shell secretion of a spherical shape formed in a species of oyster, or pearl mussel, and said to be produced by a malady in the animal, which requires nearly seven years for its full development, after which the oyster dies. Small pearls which have been immersed in acetous acids, and thus reduced to their membranous constituents, have the appearance of being formed of concentric coats of membrane, and carbonate of lime, thus resembling in composition the mother-of-pearl with which oyster-shells are lined. The precise origin of pearls is unknown, but it appears probable that some minute substance, such as a grain of sand, may have found its way into the shell and produced irritation, and that the animal, unable to expel it, renders it less injurious by covering it with calcareous matter. It is sometimes affirmed, that to produce pearls, the oyster must have received some external injury: and this is corroborated by the fact that nearly all the shells in which pearls are found are outwardly contorted, and that a smooth regular shell is a pretty sure sign of the absence of the pearl. It was therefore suggested to the Swedish government by the celebrated Linnæus, to pierce small holes in the shell of the freshly-caught pearl oyster, and then restore it to its original bed. The experiment was tried, but without success. A somewhat similar plan is said to be adopted by the Chinese, and with favourable results. These ingenious people thread upon fine silk small beads of mother-of-pearl, and fasten them within shells of pearl oysters, when they rise to the surface of the water at the beginning of summer. The animals are then restored to their bed, where they soon cover the beads with calcareous matter, and thus convert them into pearls. In whatever way pro-

duced, pearls of considerable size, on account of their beauty and rarity, have been valued at enormous prices in past ages, and are still among the choicest objects of the jeweller's art. Their delicate and silvery lustre has been as widely celebrated as the brilliance of the diamond. The Hindoos poetically describe them as drops of dew falling into the shells when the fish rise to the surface of the sea in the month of May, and becoming by some unexplained action of the sun's rays transformed into pearls. Pearl fisheries exist in Ceylon, on the Coromandel coast, and in the Persian Gulf, the last-named being the most productive. Fisheries of less importance also exist in Algiers, and in the Zooloo Islands. Two thousand years ago, the Romans found pearls in Britain, and in modern times the rivers of Scotland have afforded considerable quantities, though not of the best quality. Several rivers, of Saxony, Silesia, Bavaria, and Bohemia afford pearls, and they are also found in two or three Russian provinces. There are also pearl fisheries in the western hemisphere. The coast of Columbia and the Bay of Panama have furnished considerable quantities, but they are not considered equal to the pearls of the East in shape or colour. Detailed accounts of the pearl fishery of Ceylon have been given by the Count de Noe and others, who have had ample means of watching the operations of the pearl-divers during a residence in that island. It appears that the pearl oysters occur in banks at greater or less depth in the sea on the western side of the island of Ceylon, the average depth, however, being about 12 fathoms, and the distance from the shore about 15 miles. The right to fish on these banks is sold by the Government every season, and single auction sale is generally made to one individual, who afterwards disposes of shares in the fishery to other parties. The biddings at the auction are regulated by the produce of some thousands of oysters taken from the beds at hazard. If the average quality of pearl contained in them be good, the competition is strong in proportion. The pearl fishery commences in April and lasts till towards the end of May. It attracts a concourse of visitors not only from the interior of the island, but from various parts of India, whose diversities of language, dress, and manners produce a striking effect. The sea-shore, at other times solitary, is on the eve of the fishery suddenly covered with innumerable huts, composed of a few poles stuck in the ground, interwoven with bamboo and covered with the leaves of the cocoa-nut palm: these temporary dwellings often shelter as many as 150,000 persons. The signal for commencing the fishery is given at day-break by the firing of cannon, and at that moment the several boats cast anchor in the fishing ground, for at midnight they had left the shore in an extensive fleet, so as to be on the spot at the desired moment. Each boat has its own proper bounds, beyond which it is not lawful to work, and government vessels are on the spot to see that no infringement of contract takes place. The boats each carry a captain, pilot, and 20 men, of whom 10 are experienced divers. 5 divers descend at once, the other 5 taking the plunge when the first ascend. Thus a little time is allowed for regaining strength. In order to descend as rapidly as possible through the water, the diver places his feet on a large stone made fast to one end of a rope, the other end being secured to the boat. He also takes another rope, to the end of which is attached a net, or basket, to contain the oysters. The upper extremity of this second rope is held by two men in the boat. The diver is also provided with a strong knife for detaching the oysters, and as a means of defence against sharks, which are very numerous in those seas, but which do not often attack the divers, being perhaps scared by the noise of the assemblage, and the continual plunging of so great a number of persons. The diver no sooner reaches the ground than he gathers oysters with all possible speed into his basket, and then letting go the rope to which the stone is attached, he pulls that which is held by the sailors, and rapidly ascends to the surface. Some divers make very dexterous use of their feet, holding the net with one foot, clasping the stone with the other, and thus leaving one hand free to close the nostrils, while the other hand holds the rope in descending. The time during which the divers can remain submerged is variously stated, and no doubt it differs greatly according to the constitution of the individual. Some observers declare that in their experience it never exceeded 50 seconds; but Captain Percival, in his work on Ceylon, gives two minutes as the usual time of remaining under water. Dr. Faraday found that by first exhausting the lungs, by several deep exhalations, so as to expel the carbonic acid, and then taking deep inspiration of fresh air, he was able to hold his breath for two minutes and a half. Serious effects are produced by this employment, and the divers may frequently be seen with blood issuing from their mouth and nostrils. Yet this does not hinder them from going down in their turn. They will make from 40 to 50 plunges in one day, and bring up on each occasion about 100 oysters. Their day closes before noon, for as soon as the sea-breeze sets in, the signal is given for the return of the boats to the shore. Their owners, and a large assemblage of persons of all classes, are eagerly looking out for the arrival of the flotilla, and are soon busily employed in examining and stowing away the cargoes. Each owner has a shallow pit fenced round and secured for his own use, in which his store of oysters is deposited, and left open to the air. This pit, or *coutto* as it is called, is in the midst of a group of huts belong-

ing to the same owner, so that it is under the guard of his party. Here the oysters are allowed to putrefy under a burning sun, and a stench arises from them which would seem enough to depopulate the shore of its thousands of inhabitants. Yet such is not the case. The health of the people does not appear to be materially affected, and the oysters are allowed to remain till dry, when they can be easily opened and the pearls extracted. To open them when fresh would require much greater force, and would be likely to injure the pearls. When the putrefaction is sufficiently advanced, the oysters are taken from the *coutto*, and placed in troughs made of the trunks of trees. Sea-water is thrown over them: they are easily opened, and render their pearls to the washing and shaking of a number of men who stand all on one side of the trough, while inspectors at each end closely watch their proceedings, and other inspectors examine the shells which are thrown away, lest they should contain some of the precious substance. The workmen engaged in washing pearls dare not lift their hands to their mouths under penalty of a flogging, yet a man will sometimes contrive to swallow a pearl of high price. After all the pearls are washed out, the largest are carefully picked out from the sand at the bottom of the troughs and washed repeatedly in clean water: the next in size are spread out on white napkins to dry in the sun. The remainder are left to the care of women, who pick them up and dry them. Pearls are assorted by means of three sieves placed one above another, the meshes in which are smaller as the pearls descend. Thus the pearls which will not pass through the uppermost sieve are of the first class, and so on with the others. Another assortment is made as to colour, regularity of form, &c., and here the tastes of different nations have to be consulted. The Europeans prefer pure white pearls, the Indians yellow pearls, and the natives of Ceylon those which are tinged with rose-colour. Besides the number of persons who arrive in Ceylon in the fishing season for the sake of speculating in pearls, there are also numerous Indian artisans who are very expert in piercing and drilling pearls, and who practice their trade on the spot on economical terms. Captain Percival thus describes their operations:—"A machine made of wood, and of a shape resembling an obtuse inverted cone, about 6 inches in length and 4 in breadth, is supported upon 3 feet, each 12 inches long. In the upper flat surface of this machine holes or pits are formed to receive the larger pearls, the smaller ones being beat in with a little wooden hammer. The drilling instruments are spindles of various sizes, according to that of the pearls; they are turned round in a wooden head by means of a bow handle, to which they are attached. The pearls being placed in the pits which we have already mentioned, and the point of the spindle adjusted to them, the workman presses on the wooden head of the machine with his left hand, while his right is employed in turning round the bow handle During the process of drilling he occasionally moistens the pearl by dipping the little finger of his right hand in a cocoa-nut filled with water, which is placed by him for that purpose; this he does with a dexterity and quickness which scarcely impede the operation, and can only be acquired by much practice. They have also a variety of other instruments both for cutting and drilling the pearls. To clean, round, and polish them to that state in which we see them, a powder, made of the pearls themselves, is employed. These different operations in preparing the pearls occupy a great number of the black men in various parts of the island. In the black town or pettah of Columbo, in particular, many of them may every day be seen at this work, which is well worth the attention of any European who is not already acquainted with it."—*Tomlinson*.

(6151) PEARLS, ARTIFICIAL. The art of making artificial pearls has been brought to such perfection in Paris, that even jewellers and pawnbrokers have occasionally had a difficulty in deciding between the artificial and the real. The origin of this successful imitation is given as follows: A French bead maker named Jaquin, observing that when the small fish called *ablette*, or bleak (*Cyprinus alburnus*), was washed, the water was filled with fine silver-coloured particles, collected some of these for the purposes of his trade. He found that the soft shining powder thus obtained had to a remarkable degree the lustre of pearls; hence, he called it essence of pearl, or *essence d'orient*. He first made small beads of gypsum and covered them with this substance: they were greatly admired and eagerly sought after; but it was found that this pearly coat, when exposed to heat, separated itself from the bead, and attached itself to the skin of the wearer, in a manner that was anything but pleasant. The ladies themselves, it is said, suggested to Jaquin, the making of hollow glass beads, and covering the inside with essence of pearl. This he did, and established a manufacture, of which some idea may be gained by the following account. Slender tubes of glass are first prepared, called *girasols*, a term applied to opal, and sometimes to the stone called cat's-eye, and given to these tubes because the glass is of a peculiar bluish tint. From these the artist blows minute globules, to the extent of from two to six thousand per day, not caring to make them all perfectly regular, or free from blemish, because the natural pearls are not so. The pearl essence is then mixed with a solution of isinglass, and is blown while hot into each bead by means of a fine glass pipe. The solution is spread equally

over the whole internal surface, by shaking the pearls in a vessel placed over the table where the workman sits, and to which he gives motion by his foot. When the varnish is equally diffused and dry, the beads are filled with white wax; this gives them the necessary weight and solidity, and renders them less fragile. They are then bored with a needle, and threaded on strings for sale. The holes in the finer sort are lined with thin paper, that the thread may not adhere to the wax. To produce one pound of scales no fewer than 4,000 fishes are required; but this quantity of scales only yields 4 ounces of pearl essence. The fish are about 4 inches long; they are sold at a cheap rate in the markets after being deprived of their scales. The value of a pound of washed scales in the Chalonnais is from 15 to 25 livres The early manufacturers suffered great inconvenience from not knowing how to preserve the scales from putrefaction, and consequently being obliged to use the essence immediately it was obtained, lest it should acquire the intolerable odour of decayed fish. Attempts were made to preserve them in spirit of wine or brandy, but those liquors wholly destroyed their lustre. At length it was discovered that these fishy particles can be kept for a long time in solution of ammonia, and this enables the manufacturers of artificial pearls to carry on a considerable traffic with distant places where the fish is plentiful, the supply from the Seine, though abundant, being insufficient for the purposes of the trade of Paris. Down to a late period the heirs of M. Jaquin continued to manufacture pearls to a considerable extent, in the Rue de Petit Lion, at Paris. An elaborate account of this art is given by De Beost in a work entitled, "*L'Art d'imiter les Perles fines.*" from which most English descriptions of this manufacture have been obtained.—*Tomlinson.*

(6132) PEARLASH. The term is applied to calcined potash. It has a spongy texture, and a whitish pearly lustre. Pearlash, can be prepared from nitre and charcoal.

(6133) PEARL, MOTHER OF.

Seepie Moothoo. TAM. | Indong Mootiara. MALAY. Sudf, HIND.
Gohur parvur, PERS.

Mother of Pearl is commonly sold by the Lubbie Stone Merchants, cut into beads and other ornaments which first they call Surat Munnie, owing to their being brought from Surat.—*Ains. Mat. Med.* *False pearls* are sent from China to India for ornaments, as well as employed by the Chinese.

(6134). PEASE. PISUM SATIVUM.

Wan, JAP. | Puttanie, TAM.

The product of a well-known leguminous plant, of which two species are commonly distinguished in Britain; the grey field pea, and the white or yellow pea. Of these two species there are many varieties. Leguminous crops are very extensively cultivated in India.—*Faulkner.*

The large white, green, and brown, are now the common pea in the Deccan; the latter sort are boiled and eaten often in the shell. Peas may be sown in the beginning of June, and continued at pleasure until February, when the weather becomes warm and the stalks dry up, although I have known peas to be had much later in the sheltered gardens in the city of Aurungabad. The method of sowing is very simple; they should not be too thin, or placed deeper in drills than two inches, and a space of three feet between the rows. I generally sow my first crop in double rows, with a space of a foot between: when they are ready to climb, I earth up both sides well, leaving room for the water to run in the middle. I then place good strong sticks in the centre of the rows, and on the outer side of each lay good old manure, after which little trouble is required. Keeping them free from weeds is of course essential, and if you wish to preserve the seed, take care and remove any of the plants that appear of a different kind when in blossom; also draw out all the thin and bad looking plants, to prevent the pollen impregnating the good, and if this seed be the produce of the rain crop, you will find that if sown again in the cold weather they will be much finer and last longer than the seeds of the former season. I was led to observe this from seeds that had fallen and grown up of themselves. If you sow for late crops, I recommend their being put down in single rows, and the lines from east to west: this enables the sun to act upon the whole, and tends to prevent mildew from damp on the stalks. In growing crops that you do not intend to stick, it is advisable to put brushwood on one side for them to creep over, and prevent much loss in seed from damp and otherwise. —*Riddell* The kinds that grow best at Madras are the Bangalore and Cape seed, sown in drills after the heavy rains are over. The best manure for this vegetable is street sweepings and wood ashes: do little good at Madras after the middle of February. May be sown successively once a fortnight during the cold months. Native country unknown.

The *Japan pea* has been introduced into the United States, and return two and three hundred per cent. Agricultural Report for 1854 from Commissioners of Patents to House of assembly.

(6135) PEAT. A kind of fuel, composed chiefly of the decayed fibres of mosses.—*Faulkner.* On our arrival at Calcutta in the following February, Dr. Falconer showed us specimens of very modern peat, dug out of the banks of the Hoogly, a few feet below the surface of the soil, in which

were seeds of the *Euryale* ferox: this plant is not now known to be found nearer than Dacca (sixty miles North East, see p. 255), and indicates a very different state of the surface at Calcutta at the date of its deposition than that which exists now, and also shows that the estuary was then much fresher.—*Hooker.* This peat Dr. Falconer also found to contain bones of birds and fish, seeds of *Cucumis Madrazpatana* and another Cucurbitaceous plant, leaves of *Saccharum Sara* and *Ficus cordifolia*. Specks of some glistening substance were scattered through the mass, apparently incipient carbonisation of the peat.—*Hooker Him. Jour. Vol.* II. *page* 341.

(6136) PECTINIDÆ, OR OSTREIDÆ, a family of Conchiferous *Mollusca*, to which the common Oyster belongs. It has the following characters:—Shell inequivalve, slightly inequilateral, free or adherent, resting on one valve; beaks central, straight; ligament internal; epidermis thin; adductor impression single, behind the centre; pallial line obscure; hinge usually edentulous. Animal marine; mantle quite open, very slightly adherent to the edge of the shell; foot small and byssiferous, or obsolete; gills crescent-shaped, two on each side; adductor muscle composed of two elements, but representing only the posterior shell-muscle of other bivalves. (Woodward.) The principal genera referred to this order are—*Pecten*, *Ostrea*, *Lima*, *Placuna*, *Anomia*, *Placunomia*, *Hinnites*, *Spondylus*, and *Plicatula*.

Pecten (Lamarck).

(6137) PECTEN PLERURONECTES. Shell sub-equivalve, rather thin, smooth externally somewhat convex on both sides. This species has the upper valve always coloured, generally reddish or rich reddish-brown and the lower one white, whence its name. In the inside of the valves are projecting radiated somewhat distant ribs. It is found in the East Indian seas, and fossil in France, at St. Paul-Trois-Chateaux, in the department of Drome.—*Eng. Cyc.*

(6138) PECTEN SPONDYLOIDEUM, is the only species. The shell is ovato-cuneiform, planulate; whitish tinged with red or purplish, especially near the umbones; the upper valve flat and striated longitudinally; the lower valve largest, with the lateral edges turned up and raised above those of the upper valve. There is a smaller variety, much more round, and generally more delicate. It is a native of the East Indian Seas (Isle of France, &c.), where it is found half-imbedded in coral-reefs.

(6139) *Ostrea* (*Gryphæa* (Lam.), fossil principally;

(6140) *Exogyra* (Say), fossil only).

(6141) *Placuna* (Brug.).—Animal very much compressed. The species now known are from the East Indian and Red Seas, and have been taken on sandy bottoms. M. Deshayes remarks that the animal is not known, but that he is convinced that it has a great analogy to that of *Anomia*. The number of species recorded in the list of M. Deshayes is three living and one fossil (tertiary).

(6142) PEDALIACEÆ, a natural order of Monopetalous Exogenous Plants, very nearly related to *Verbenaceæ*, having like it irregular and usually didynamous flowers and a few-seeded 2- or 4-celled fruit; but differing in having the radicle directed towards the base instead of the apex of the fruit. From *Bignoniaceæ*, with which they are more generally compared, their wingless seeds offer the principal distinction. They are all exotic tropical herbaceous plants, with opposite leaves and axillary flowers, and are of little known use, with the exception of the genus *Sesamum*, whose seeds afford a bland oil not inferior, when fresh, to that of the olive. [SESAMUM]

(6143) PEDALUM MUREX. An infusion of this Pedalium,—*Gokeroo*, is a good mucilaginous demulcent, much used by the natives as a drink in gonorrhœa.—*Beng. Phar. p* 304.

(6144) PEDALIUM MUREX. Nat. BURRAY-GOKERROO. A succulent plant, with small yellow flowers which appear in the rains, the green leaves when agitated in water render it mucilaginous: this is prescribed by the natives in dysuria, the seeds are supposed to possess similar virtues.

(6145) PEDALIUM MUREX. PRICKLY FRUITED PEDALIUM. Lin.

Anaueringie, TAM.	Khussuke kubeer, ARAB.
Burra gokeroo, HIND. and DUK	Yeanugapulleroo, TEL.
	Ghejasoodumoostra, SAN.

A pretty large plant, with small yellow flowers which appear in the rains.—*Riddell.* Succulent, ramous, annual, growing generally over the country, but chiefly on the Coromandel coast, in a moist sandy soil; flowers in the rainy and cold seasons. The fresh leaf of this plant, when agitated in water, renders it mucilaginous, in which state it is prescribed by the natives, in cases of Dysuria and Ischuria. The seeds which are contained in the prickly capsule are supposed to have similar virtues and are administered in decoction. This plant is called Caca Mullu in the Hort Mal.—*Ains. Mat. Med. page* 69. The fresh plant renders water or milk very mucilaginous without altering the taste, colour, or smell of the liquid. This thickening disappears in a few hours. A watery infusion of this kind sweetened with sugar is a favourite and excellent native demulcent in acute gonorrhœa. Butter milk is often fraudulently thickened by the use of the leaf. *Roxb. Fl. Ind.* iii. *p.* 114.—*O'Shaughnessy, page* 480.

(6146) PEDDA JANY.

Pidda janee, TEL.	Buree janee, HIND.

Pidda tapasee, TEL.	Burree tapasee, HIND.

(6149) PEDDAWK WOOD.

Peddawkoo kurra, TEL.

(6150) PEDILANTHUS TITHYMALOIDES, JEW BUSH. West Indies. Introduced into the Calcutta Garden, and now common everywhere about Calcutta in hedges. A shrub about 6 feet high, abounding in white bitter milk, known and used in America as ipecachuana: in numerous trials no proof was obtained of its efficacy; this is probably the result of deterioration of properties through the influence of the climate of Bengal.—*O'Shaughnessy, p.* 566. This American plant, which is used in the West Indies as a substitute for ipecacuanha, is seen in cultivation occasionally, and in the neighborhood of Calcutta it is an abundant as a wild plant.—*Mason.*

(6151) PEEDOO MARUM.

Peedoo Marum, TAM. | Peemah wood, ENG.

A small tree wood used for building in Wynaad where it grows plentifully.

(6152) PEGANUM, from πήγανον, the Greek name of Rue, of which three kinds are described by Dioscorides—the Garden, the Mountain, and the Wild. The last is said to be called Moly in Cappadocia and Galatia, and by some Harmala. It is remarkable that even in the present day a plant is found in the north of India, the Punjab, and Cabul, which is called Hoormul by the natives of the above countries, and sometimes distinguished in India by the name of Lahooree-Hoormul, indicating that it was introduced from the direction of Lahore. The Persian works on Materia Medica in use in India give Molee as its Greek name, according to Dr. Royle ('Illustr.,' p. 155). It is interesting to find that the plant to which these names are assigned by the natives of the country is the *Peganum Harmala* of botanists, a fact which shows that the investigations of the West had arrived at the same conclusion as those in the East respecting the plant alluded to by Grecian authors; and this enables us to put more faith in the results of such investigations than is sometimes done. The plant, which is called Syrian Rue in gardens, belongs to the natural family of *Rutaceæ*, and is of easy culture in any light soil. The seeds, which were formerly in use in medicine in Europe, still are so in the East, but are not possessed of any peculiar or very active properties.—*Eng. Cyc.*

(6153) PEGANUM HARMALA, occurs in many parts of India, and is found in the Taj garden at Agra. The seeds are used in native medicine, and called Lahoree Hoormul. In the "Mukzzunul-Udwieh," the seed is called *Moolie*; the same as the πήγανον, of Discorides. Royle, p. 155.—*O'Shaughnessy, p.* 260.

(6154) PEKEA, a genus of Plants inhabiting Guyana, and furnishing the Saouari or Sawarra Nuts of the shops, a very different fruit from that to which the name of Saouari is given in Guyana. *Pekea* comprehends two species, the *P. butyrosa* and *P. tuberculosa*: the former is unknown in this country; the latter, which yields the fruit in question, is a very large tree inhabiting the woods of Guyana, were it is called Tatayouba by the Garipou Indians. It has opposite digitate leaves, whose leaflets are oval, smooth on the upper side, but white with down beneath; the terminal leaflet is said to be 8 inches long by 3½ inches in breadth, while those at the sides are much smaller. The flowers are unknown. The fruit consists of greenish compressed drupes, which adhere around a common centre, and contain a single seed of large size, covered with a brownish rugged woody shell, and containing a kernel of a soft consistence, and of the most delicate buttery quality. It is by far the best of the South American nuts that are brought to England, and much superior to English walnuts, almonds, and filberts; but it is scarce and dear in most seasons.—*Eng. Cyc.*

(6855) PELARGONIUM is the name given by botanists to the gaily painted flowers which are usually called Geraniums in greenhouses. The latter differ obviously from *Pelargonium* in having regular flowers, and in being herbaceous plants, while the genus in question consists almost entirely of shrubs with flowers as irregular as those of the Pansy. There is a large number of genuine species of this genus, chiefly inhabiting the Cape of Good Hope; and as these intermix very readily, producing in great abundance shrubs which are capable of being perpetuated by cuttings, a prodigious number of spurious species, as well as acknowledged varieties, have found their way into the writings of systematic botanists. For example, De Candolle enumerates 369 supposed species, of which at least one-half are of artificial origin. While however science has been embarrassed by this facility of cross breeding, the gardens have been enriched by crowds of the most beautiful objects, in which the features of their savage progenitors can no longer be recognised; and it is probable that of all the flowers which have been acted upon by the hand of man, the *Pelargonium* is that in which the result has been most striking. By care and attention to a few simple points of practice these plants may be cultivated and multiplied by any one who has a greenhouse, and hence they have become universal favourites. These points are the following, namely:—1, water; 2, warmth; 3, a gentle bottom heat; 4, abundance of air; 5, as much light as the leaves will bear; and 6, a rich soil during the season of growth; and a cool atmosphere, less water, abundance of light, and close pruning afterwards—*Eng. Cyc.* Many kinds of this genus, thrive well in India and are easily raised from seed, the Horseshoe and Oak-leaf bear flowers abundantly, but it

is generally remarked that plants grown from English seed do not blossom. Many of the species thrive well when put out in the garden, but are better for being grown in large pots, and if so placed, as only to receive the morning and evening sun, will blossom most abundantly.—*Riddell.*

(6156) PELAN. A very hard, fine, close-grained, heavy Ceylon wood.

(6157) PELECANIDÆ, a family of *Natatores*, or Swimming birds. The genus *Pelecanus* of Linnæus, placed in the 'Systema Naturæ' between *Diomedea* and *Plotus*, contains the True Pelicans (*Pelecanus Onotrocalus*), the Frigate Bird or Man-of-War Bird (*Trachypetes*), under the designation of *P. aquilus*, the Cormorants (*P. Carbo* and *P. Graculus*), and the Solan Goose and Boobies.

Pelecanus (Linn. —Bill long, straight, wide, very much depressed; upper mandible flattened, terminated by a very strong hook or nail, which is compressed and very much bent; lower mandible formed by two osseous branches, which are depressed, flexible, and united at the point, and from which a naked skin in the form of a bag is suspended. The species of *Pelecanus* are widely spread (Europe, Asia, Africa, and America), though not numerous: two are European, P. *Onocrotalus*, and *P. Crispus*.

Phalacrocorax (Brisson).—Bill moderate or long, straight, compressed. This is the genus *Halieus* of Illiger, *Carbo* of Meyer, and *Hydrocorax* of Vieillot.—*Eng. Cyc.*

Pelecanus carbo, the Common Cormorant. (Old.) Under the throat a large white or whitish collar, the upper extremities of which reach to just below the eyes. The geographical distribution of this bird is very extensive. It is an inhabitant of the New as well as the Old Continent. In the latter it is widely diffused. It is spread over a considerable portion of Europe, especially the north. It is a common bird in England. Its voracity is indeed great, and the way in which it will dispose of a large fish, a place for instance, aided in a great measure by the powers of compression and dilatation conferred on it by the apparatus noticed above, is surprising. The species is easily domesticated. Montagu, who kept one, gives a favourable account of its disposition, and indeed their docility is shown by the use made of them formerly in fishing. Pennant cites Whitelock, who says that he had a cast of them manned like hawks, and which would come to hand.

(6158) *Phalacrocorax sinensis* Sir George Staunton ('Embassy to China') states that the embassy, in its journey to Han-choo-foo, "had not proceeded far on the southern branch of the canal, when they arrived in the vicinity of the place where the Leu-tze, or famed Fishing-Bird of China (*Phalacrocorax Sinensis*) is bred, and instructed in the art and practice of supplying his owner with fish in great abundance. It is a species of the Pelican, resembling the Common Cormorant, but which, on a specimen being submitted to Dr. Shaw, he has distinguished in the following terms:—'Brown Pelican or Cormorant with white throat, the body whitish beneath and spotted with brown; the tail rounded; the irides blue; the bill yellow.'" The bird, an undoubted Cormorant, is figured in the 'Atlas,' pl. 37, and a vignette at the end of the chapter shows two Chinese fishermen carrying their light boat, around the gunnel of which their cormorants are perched, by a pole, resting on their shoulders between them. Sir George further says, "On a large lake close to this part of the canal, and to the eastward of it, are thousands of small boats and rafts, built entirely for this species of fishery. On each boat or raft are ten or a dozen birds, which at a signal from the owner plunge into the water; and it is astonishing to see the enormous size of fish with which they return grasped between their bills. They appeared to be so well trained that it did not require either ring or cord about their throats to prevent them from swallowing any portion of their prey, except what the master was pleased to return to them for encouragement and food. The boat used by these fishermen is of a remarkably light make, and is often carried to the lake, together with the fishing-birds, by the men who are there to be supported by it."

(6159) PELECANUS CRISTATUS (Cormoran Largup of Temminck; Crested Corvorant of Pennant: Shag or green Cormorant of Gould) It is probable that *P. Desmarestii* is identical with *P. cristatus*. The habits of *P. cristatus* are very similar to those of *P. Carbo*.

(6160) *Plotus* (Linn., Klein).—Bill longer than the head, quite straight, firm though slender, obliquely dentilated on the edges, which are bent inwards, and terminating in a very sharp point. This is the genus *Anhinga* of Brisson; *Plotus* of Scopoli; and *Plinx* of Mœhr.

(6161) *Plotus Levaillantii* (*P. Africanus* of Swainson), It is found in Senegal, Cape of Good Hope, and part of the coast of Asia. (Lesson).

(6162) *Fregata* (Ray.) Feet short; the toes united by a membrane which is deeply notched. This is the genus *Tachypetes* of Vieillot. The Man of-War Birds, or Frigates, are eminently raptorial. Ray speaks of their eagle-eyes, vulturine claws, and kite-like glidings. Their immense extent of wing and dashing habits have obtained for them the name of the swiftest sailing ships of war that sweep the seas.

(6163) *F. Aquilus*. Tail forked, body black, bill red, orbits black. The male is entirely black: abdomen of the female white. Some accounts state the extent of the wings to be fourteen feet, an almost incredible expanse.

(6164) PELIJUREE. THALICTRUM. Root of Thalictrum foliolosum.—*Ben. Phar.*

(6165) PELLEVANDRUM (a bliater) in Ganjam.

(6166) PELLITORY: PYRETHRUM. AKURKURA.

Akurkurra. ARAB.	Akulkurra or Akkurkurha, GUZ. HIND.
Akkarapntta, CYNG.	Pietro Parietaria, IT.
Sesin. CHIN.	Akkarakarum, TAM.
Pyrethre, FR.	
Zahn, Wurtzel, GER.	

Root of Anacylus (or Anthemis) Pyrethrum.—*Ben. Phar. Anthemis Pyrethrum*, is a native of the Levant, Barbary, Persia, and the South of Europe, cultivated for its root, which is used in medicine as a masticatory and a stimulant. The root is without smell, and when dry, it is some inches long, tough, fibrous, of the thickness of a quill, externally gray, internally white. Pellitory is to be found in most Indian bazars, it being an export from Mocha to Bombay. —*Faulkner*. Ainslie says, "this root is to be found in most of the Indian bazars though I cannot learn that the plant grows in this country, I am therefore inclined to think that the medicine is brought to these provinces from the more Northern parts of Africa where we know that it is produced. With regard to its Asiatic names there is this singularity that the Tamul, Arabic and Dukhanie appellations are nearly the same. The Vytianas prescribe an infusion of Akkaracarum in conjunction with the Lesser Galangal and Ginger as a cordial and stimulant in the lethargic stage of Typhus fever and in paralytic affections. They also use it as a masticatory for the tooth ache."—*Ains. Mat. Med. p.* 34.

(6167) PENANG LAWYER. The walking stick, so well known by this name, is a young plant of the Licuala acutifida, the *Plass tikooss*, of the Malays. It is a miniature palm, inhabiting Penang, and attaining generally only three or five feet, and in exceptional cases from fifteen to twenty feet in height. The "Penang lawyers" are prepared by scraping the young trunk with glass, so as to wholly remove the epidermis, and nothing more, the inside being the substance of rattan. It is on this account that the smaller thin, sticks are so muchmore sought after than the larger thicker ones, and are so rare. The stikes are ultimately straightenedby fire, and then polished.—*Seeman*.

(6168)PENCILLARIA SPICATA: BAJREE: SPIKED MILLET. Holcus spicatus, Linn.

Kumbooloo, Sujilloo. TEL.	Bajari, GUZ.
Bajra, HIND. and DUK.	Mattaree, MAL.
Cumboo, TAM.	Caughoo, SANS.

This grain is reckoned more delicate and of a less heating nature than Cholum: like it, it is made into cakes and porridge. Park, in his Travels in Africa informs as that the Natives of some parts of that country prepare from this grain a kind of Malt, which they use for making Beer.—*Ainslie, Vol.* II. *p.* 218.—*M. C. C.*

Nulla Muddee, Tel.	Aans Beng,
Carroo Maruda, Tam.	Peeasal or Usan, Duk.
Madi, Can.	

A large jungle tree with thick leathery leaves; fruit smooth, five winged; the fibre of the wood is very tough, and used for making shafts to gigs, &c. Found in various parts of India: grows to be a large timber tree of much utility, Flowering time April and May; the seed ripens in the cool season. I have found this timber in use only in the Rajahmundry circar: it is very hard and heavy and not so stiff as teak.—*Rohde M.S.S.*

(6182) PENTAPETES PHŒNICEA, Byttneriaceæ. An erect growing plant; flowers axillary, large, of a beautiful bright red colour, appear during the rains.—*Riddell.*

(6183) PEPPER. The black pepper of commerce is obtained from the dried unripe fruit (drupes) of *Piper nigrum*, a climbing plant common in the East Indies, and of the simplest culture, being multiplied with facility by cuttings or suckers. The ripe fruit, when deprived of its outer fleshy covering by washing, forms the white pepper of the shops. The dried fruiting spikes of *P. longum*, a perennial shrub, native of Malabar and Bengal, constitute long pepper. The fruit of *Xylopia aromatica* is commonly called Ethiopian pepper, from being used as pepper in Africa. The seeds of some species of fennel-flowers (*Nigella sativa* and *arvensis*), natives of the south of Europe, were formerly used instead of pepper, and are said to be still extensively employed in adulterating it. In Japan, the capsules of *Xanthoxylum piperitum*, or *Fagara Piperita*, are used as a substitute for pepper, and so is the fruit of *Tasmania aromatica* in Van Diemen's Land. According to Dr. Roxburgh, *P. trioicum* is cultivated in the East, and yields an excellent pepper.

The pepper vine rises about two feet in the first year of its growth, and attains to nearly six feet in the second, at which time, if vigorous and healthy, the petals begin to form the corolla or blossom. All suckers and side shoots are to be carefully removed, and the vines should be thinned or pruned, if they become bushy at the top. Rank coarse weeds and parasitical plants should be uprooted. The vine would climb, if permitted, to the elevation of twenty feet, but is said to bear best when kept down to the height of ten or twelve feet. It produces two crops in the year. The fruit grows abundantly from all the branches, in long small clusters of from 20 to 50 grains; when ripe it is of a bright red colour. After being gathered, it is spread on mats in the sun to dry, when it becomes black and shrivelled. The grains are separated from the stalks by hand rubbing. The roots and thickest parts of the stems when cut into small pieces and dried, form a considerable article of commerce all over India, under the name of *Pippulamoola*. Almost all the plants of the family *Piperaceæ*, have a strong aromatic smell and a sharp burning taste. This small group of plants is confined to the hottest regions of the globe; being most abundant in tropical America and in the East Indian Archipelago, but more so in the equinoctial regions of Africa.

The common black pepper, *P. nigrum*, represents the usual property of the order, which is not confined to the fruit, but pervades, more or less, the whole plant. It is peculiar to the torrid zone of Asia, and appears to be indigenous to the coast of Malabar, where it has been found in a wild state. From this it extends between the meridians of longitude 96 deg. and 116 deg. S. and the parallels of latitude 5 deg. S. and 12 deg. N., beyond which no pepper is found. Within these limits are the islands of Sumatra and Borneo, with the Malay peninsula and part of Siam. Sumatra produces by far the greatest quantity of pepper. In 1842, the annual produce of this island was

reckoned at 30,000,000 lbs., being more than the amount furnished by all the other pepper districts in the world. A little pepper is grown in the Mauritius and the west India Islands, and its cultivation is making some progress on the Western Coast of Africa, as England imported from thence 2,9 9 bags and casks in 1846, and about 110,000 lbs. in 1847. Mr. J. Crawfurd, F.R.S., one of the best authorities on all that relates to the commerce and agriculture of the Eastern Archipelago, recently estimated the produce of pepper as follows :—

	lbs.
Sumatra (West Coast),	20,000,000
,, (East Coast)	8,000,000
Islands in the Straits of Malacca,	3,000,000
Malay Peninsula,	3 733,333
Borneo,	2,666,667
Siam,	8,000,000
Malabar,	4 000,000
Total.	50,000,000
If we add to this,	
Western Coast of Africa and B. W. Indies,	53,000
Java,	4,000,000
Mauritius and Ceylon.	80,000
It gives	54,133,000

As the total produce of the world.

Black pepper constitutes a great and valuable article of export from the Indian Islands; which, as we have seen, afford by far the largest portion of what is consumed throughout the world In the first intercourse of the Dutch and English with India, it constituted the most considerable and important staple of their commerce. The production of pepper is confined in a great measure to the western countries of the Eastern Archipelago, and among these to the islands in the centre and to the northern quarter, including the Peninsula. It is obtained in the ports on both sides of the coast of the latter, but particularly the north-eastern coast. The principal quarters (according to Mr. Crawfurd,) are Patani, Tringanu, and Kalantin. In the Straits a large quantity is produced in the island of Singapore, and above all in Pinang, where the capital of Europeans and the skill and industry of the Chinese have been successfully applied to its culture. The western extremity of Sumatra, and the north-west coast of that island, are the most remarkable situations in it for the production of pepper, and here we have Acheen, Tikao, Bencoolen, Padang, and the country of the Lampungs. The production of the eastern extremity of Sumatra or Palembang is considerable, but held of inferior quality. In the fertile island of Java, the quantity of pepper grown is inconsiderable, nor is it remarkable for the goodness of its quality. The province of Bantam has always furnished, and still continues to produce, the most pepper; but the culture of this creeper is fast giving place in Java to staples affording higher profits and requiring less care. The exports were, in the following years—

	piculs.		lbs.
1830	6,061	1843	3,737,732
1835	11,868	1848	461,680
1839	11,044	1851	95,037
1841	13,477	1852	135,690

The number of pepper vines in the district of Bencoolen, in the close of the year 1852, was as follows:—1,571;894 young vines; 2,437,052 bearing ditto; total, 4,008,946. Up to the end of September there had been delivered to the Government 1,145 piculs white pepper, and 1,128 piculs black pepper, while of the harvest of 1852 there were still probably to be received 330 piculs white, and 4,967 piculs black pepper. The south, the west, and the north coasts of the great island of Borneo produce a large quantity of pepper; as early as 1721 it was a staple commodity of this island. Banjarmassin is the most productive place on the south coast, and the State of Borneo Proper on the north coast. The best pepper certainly does not grow in the richest soils, for the peppers of Java and Palembang are the worst of the Archipelago, and that of Pinang and the west coast of Sumatra are the best. Care in culture and curing improves the quality, as with other articles, and for this reason chiefly it is that the pepper of Pinang is more in esteem than that of any other portion of the Archipelago. From the ports and districts of Siam 3,500 to 4,000 tons are exported annually. The duty at present levied on pepper in England is 6d. per lb., while the wholesale price for that of Pinang, Malabar, and Sumatra is about 4d. per lb. White pepper ranges from 9d. to 1s. 6d. per lb. The prime cost in Singapore is not more than 1½d. per lb. About 70,000 or 80,000 piculs of pepper are annually exported from Singapore, of which between 30,000 and 40,000 piculs have, until within the last two years, gone on to Great Britain. More than one-half of the pepper exported from Singapore is grown in the island by Chinese settlers. The low selling price of the article in the English market, the high duty levied upon it, and the large freight paid for its carriage to Great Britain, now leave so small a price to the cultivator in Singapore, that the cultivation ceases to be remunerative, and is carried on at a loss; and has consequently within the last year or two begun to decrease rapidly, involving the Chinese growers, who are generally of the poorest class, and without capital, in great distress. A reduction in the duty on pepper has always been followed by a very large increase in the consumption of the article, as will appear from the following table, showing the importation and consumption in Great Britain during some of the first and last years of the different rates of duty :—

Year.	Quantity consumed.	Duty s.	d.	Singapore price s.	d.	s.	d.
1811 ...	1,457,383 ...	1	10½ ..	0	7½ to	0	7¾
1814 ...	941,569 ...	1	10½ ..	0	11 „	1	1
1820 ...	1,404,021 ...	2	6 ..	0	6½ „	0	6¾
1824 ...	1,447,030 ...	2	6 ..	0	4½ „	0	5½
1826 ...	2,529,027 ...	1	0 ..	0	4 „	0	4½
1836 ...	2,749,491 ...	1	0 ..	0	0 „	0	0
1837 ...	2,625,075 ...	0	6 ..	0	0 „	0	0
1845 ...	3,210,415 ...	0	6 ..	0	2½ „	0	4¾

In a memorial from the mercantile community of Singapore, sent home in 1848, it is asserted that a reduction in the duty of pepper being always attended by a large increase in the consumption, would not lead to any serious loss in the revenue, while it would confer a great boon on the poorer classes, to whom it has now become a necessary article of life. The reduction would also be of great advantage to British manufacturers, as well as to our Indian possessions, by giving rise to an increased demand for British goods and productions, and of the highest benefit to the agricultural settlers in the island of Singapore, by enabling them to procure for their labor an honest means of livelihood. The pepper vines, which are allowed to climb poles or small trees, are tolerably productive at Singapore; and pepper planting is esteemed by the Chinese to be a profitable speculation, particularly if they are enabled to evade the payment of quit-rent. An acre of pepper vines will yield 1,161 lbs. of clean pepper. In Sumatra a full grown plant has been known to produce seven pounds; in Pinang the yield is much more. The average produce of one thousand vines is said, however, to be only about 450 lbs. Colonel Low, in his "Dissertation on Pinang," published at Singapore some years ago, gives an interesting account of the culture:—"Pepper was, during many years, the staple product of Pinang soil, the average annual quantity having been nearly four millions of pounds; but previous to the year 1810, the above amount had decreased to about two-and-a-half millions of pounds, which was the result of the continental system. The price having fallen at length to three and three-and-a-half dollars the picul—with only a few occasional exceptions of rises—the cultivation of this spice was gradually abandoned, and the total product at this day does not exceed 2,000 piculs. The original cost, when pepper was at a high price, together with charges of transporting it to Europe, amounted to £86,357 for every five hundred tons, and the loss by wastage was estimated at £5,405. In 1818 there remained on this island 1,480,265 pepper vines in bearing, and the average value of exports of pepper, from Pinang, including that received from other places was averaged at 106,870 Spanish dollars. As might have been foreseen, the fall of prices has so greatly diminished the cultivation of pepper to the eastward, that a reaction is likely to take place; and has in fact partly shown itself already. Some Chinese in Pinang and Province Wellesley seem to be preparing to renew the cultivation. There is abundant scope for the purposer on both sides of the harbour, and every facility is at hand for carrying it on. The pepper plant or vine requires a good soil, the richer the better, but the *red* soil of the higher hills is not congenial, the Chinese think, to it. The undulations skirting the bases of the hills, and the deep alluvial lands, where not saturated with water, or liable to be overflowed, are preferred. The Chinese have always been the chief cultivators, and when the speculation flourished they received advances from the merchants, which they paid back in produce at fixed rates. When pepper was extensively cultivated on Prince of Wales Island, the European owner of the land had the forest cleared by contract, and the vines planted by contract, and when the vines came into bearing the plantation was farmed to the Chinese from year to year, on payment of a specific quantity of pepper. Any other plan would have ruined the capitalist, as the culture is almost entirely in their hands in the Straits' Settlements, and they will not work so well for others as when they are specially interested. The Plants are set out at intervals, *every way*, of from seven to twelve feet, according to the degree of fertility of the soil, so that there are from 800 to 1,600 vines in one orlong of land; to each vine is allotted a prop of from ten to thirteen feet high, cut from the thorny tree called *dadap*, or where that is scarce, from the less durable *boouglai*; these props take root, thus affording both shade and support to the plant. The plant may be raised from seed pepper, but the plan is not approved of, cuttings being preferable, as they soonest come into bearing. The pits in which these cuttings are set should be a foot-and a-half square, and two feet in depth; manure is not often applied, and then it is only some turf ashes. However unpicturesque a pepper plantation may be, still its neat and uniform appearance renders the landscape lively, and there can be little doubt that the island has suffered in its salubrity since the jungle usurped the extensive tracts formerly under pepper cultivation. When the vine has reached the height of three or four feet, it is bent down and laid in the earth, and about five of the strongest shoots which now spring up are retained and carefully trained up the prop, to which they are tied by means of ligatures of some creeping plants. One Chinese, after the plantation has been farmed, can take care of two orlongs of land. The usual mode is this:—an advance is made by the capitalist to the labourer for building a house, and for agricultural implements; he then receives two dollars monthly to subsist on, until the end of the third year, when the estate or plantation is equally divided betwixt the contracting parties. The Chinese and even European cultivators used

formerly to engage the Chinese who had just arrived from China; they paid off their passage-money, and then allowed them two dollars monthly, for provisions, for one year, with a suit of clothes, by which means the cost of the labor of one man averaged about three dollars monthly; but this plan is attended with risks. The cost attendant on the cultivation of two orlongs of land, with pepper, for three years—the Chinese laborer receiving the usual hire of *five* Spanish dollars monthly—will be nearly as follows:—

	Spanish dollars.
Price of land, clearing, and planting.....	40
Quit rent, at 75 cents per annum per orlong	9
Two thousand plants.....	4
„ dadap props.	6
Implements.....	6
House	10
Labor.....	200
Interest, loosely calculated at	30
Total Spanish dollars.....	305

In a very good soil a pepper vine will yield about one-eight of a pound of dry produce at the end of the first year; at the end of the second, about a quarter of a pound; and at the expiration of the third, probably one pound; at the end of the fourth, from three to three-and-half pounds; ditto fifth, from eight to ten pounds. After the fifth year up to the fifteenth, or even the twentieth year, about ten pounds of dry merchantable produce may be obtained from each vine, under favourable circumstances. The Chinese speculator used to rent out his half-share of a new plantation for five years, to his cultivating partner, after the expiration of the first three years, at the rate of thirty piculs per annum; the total produce of these five years giving about fifty-six piculs annually as an average. A pepper plantation never survives the thirtieth year, unless in extremely rich soil, and then it is unproductive; nor will the young vine thrive on an old worn out pepper land, a peculiarity which is applicable to the coffee tree. The chief crop lasts from August to February. Four pounds of dry produce, for ten of green, is considered a fair estimate. Great care is requisite in the management of the vine, and especially in training and tying it on the props. It is subject to be injured by the attacks of a small insect. The green pepper dries in two or three days, and if it is intended that it shall be black, it is pulled before it is quite ripe. To make white pepper, the berry is allowed to remain somewhat longer on the vine; it is, when plucked, immersed in boiling water, by means of which process and subsequent friction, before drying, the husk is separated. The exports of pepper from Pinang in four years have been—In 1849, 2,591,233 lbs.; in 1850, 6,397,783 lbs.; in 1851, 2,366,933 lbs.; in 1852, 2,142,133 lbs." A small quantity of pepper seems to be annually exported from Ceylon, which is presumed to be the growth of that islands; thus there were:—

54	cwts.	shipped in	1842
83	„	„	1843
102	„	„	1844

In the Customs returns of Ceylon, it is classed with cardamoms, and 160 to 170 cwt. of the two were shipped in each of the years 1850 and 1851. In 1852, the quantity was smaller. Pepper cultivation has been introduced into the Mauritius, and in 1839 more than 500,000 lbs. were imported from thence, but as the shipments have since decreased, it has, it is is presumed, given place to the more profitable staple sugar.—*Simmonds, p.* 428. The natural family piperaceæ includes four plants of great utility to mankind. Two of these, Piper nigrum or black pepper and Piper longum more recently named Chavica Roxburghii or long pepper are chiefly used for dietetic and culinary purposes while others piper Cubeba now Cubeba Officinalis and Artanthe elongata or the matico plum are principally employed in medicine. The plant which yields cayenne, Capsicum annuum, often improperly termed cayenne pepper does not belong to the family of Piperaceæ at all but to that of Solenaceæ. The pepper of commerce is furnished by Piper nigrum, and it is to this species, therefore, that on the present occasion we shall have to direct attention. The black pepper plant grows both in the East and West Indies, in Sumatra, Java, and other islands, it is a shrubby, climbing plant, which attains the height of from eight to twelve feet. The berries, or peppercorns, grow on terminal flowers-stalks or spadices. They are at first green, but change subsequently to red and then to black. When any of the berries on a spadix have begun to turn red, the whole are gathered, dried in the sun, and the stalks separated by the hand. In drying, the succulent part of each berry becomes contracted and wrinkled, forming a hardened wrinkled cortex, the corrugations being much raised, and describing a kind of elevated network. The following more detailed particulars concerning the growth of the pepper plant and the gathering of the berries are extracted from M'Culloch's "Dictionary of Commerce." "It climbs to the height of twenty feet but is said to bear best when restrained, to the height of twelve feet. It begins to produce at about the third year, and is in perfection at the seventh; continues in this state for three or four years; and declines for about as many more, until it ceases to be worth keeping. The fruit grows abundantly from all its branches, in long, small clusters of from twenty to fifty grains. When ripe it is of a bright red color. After being gathered it is spread on mats in the sun, when it loses its red color and becomes black and shrivelled as we see it. The

grains are separated from the stalks by hand-rubbing. That which has been gathered at the proper period shrivels the best but if plucked too soon, it will become broken and dusty in its removal from place to place. The vine produces two crops in the year but the seasons are subject to great irregularities. Those berries are the best which are not too small nor too much corrugated, which are heavy and sink readily in water. The two varieties of pepper known as "black" and "white" pepper are both obtained from the same plant: black ground pepper is the entire berry reduced to powder, while the white consists of the same berry, decorticated or deprived of its outer and black husk or covering. We learn from Pereira that three kinds of black pepper are distinguished by wholesale dealers. These are:—"Malabar pepper.—This is the most valuable it is brownish-black free from stalks and nearly free from dust." "Penang pepper. This is brownish-black larger, smoother, free from stalks, but very dusty. It is sometimes used in England to manufacture white pepper." "Sumatra Pepper. This is the cheapest sort; it is black mixed with stalks and contains much dust. Under the name of Sumatra pepper, some dealers include the Penang or brownish-black sort, and the black Sumatra sort. Three kinds or varieties of white pepper have also been distinguished. "Tellicherry pepper, which is of two kinds: large fine Tellicherry pepper is larger and whiter than any other description of white pepper, and fetches a higher price; small or coriander-like pepper is shrivelled." Common white pepper comes from Penang by Singapore, it is round, and not shrivelled, its value depends on its size and whiteness." "English bleached or White pepper. When the two preceding sorts are scarce, brown, Penang pepper is bleached. The yellowest and largest are chosen for this purpose for neither an expensive nor small sort would pay."

Structure of the Berry. The berry of the black pepper plant possesses a structure of considerable complication and of much interest and since without an accurate knowledge of its minute orginisation we cannot hope to be in a position to detect the numerous adulterations to which this article is subject, it becomes necessary to describe somewhat minutely the tissues which enter into its formation. In a section of the berry, two parts are to be distinguished an outer and an inner, the first is black or reddish black; and the second more or less, white, hard and brittle, except in the centre of the seed where it is frequently soft and pulverulent. The active properties of black pepper depend upon an acrid resin, a volatile oil, and a crystallisable substance called piperine, which exists also in long pepper, and in cubebs. The resin is situated chiefly in the outer part of the cortex, the volatile oil in the inner part or fourth layer, and the piperine in the yellow cells of the seed itself. It has long been notorious that pepper is one of those articles most liable to adulteration, notwithstanding which fact and the importance of the subject in a fiscal point of view, but little has hitherto been effected in bringing to light the nature of the sophistications practised, and more particularly in describing the methods of their detections. Of statements indeed we have several but of either proofs or directions scarcely any worthy of notice or entitled to confidence. In support of these assertions, we proceed to make reference to the more important as well as recent authorities on the subject of the adulteration of food. Thus in the "Supplement" to Dr. Ure's "Dictionary of Arts, Manufactures and Mines," we do not meet with any information respecting the adulteration of pepper worth quoting. In M'Culloch's "Commercial Dictionary" we observe the solitary remark, "Black pepper, sold ground is said to be adulterated with burnt crust of bread." In Mitchell's "Treatise on the Falsification of food" we find the following observations. "In the state of powder pepper is nearly always adulterated; substances being sold for the express purpose. It is often mixed with powdered husks of mustard, which are openly sold for this purpose, as is also the sweeping from the pepper warehouses under the name of P. D. or Pepper dust; and yet an inferior kind of these adulterations is sold under the name of D. P. D. signifying the dust or dirt of pepper dust." No directions, be it observed, are given for the detection of the adulterations referred to in the above quotation. Normandy, in his "Commercial Handbook of Chemical Analysis," remarks, "Both black and white pepper, when ground, are very often adulterated, and sometimes in an extraordinary degree, with ground oil-cake, linseed-meal, and other like substances. The best way of providing against adulteration is, like that for coffee, to buy the article in the grain, and to examine whether it has the appearance which we have described above, and which is the criterion of a good quality," and in a subsequent paragraph he writes. "For the purpose of ascertaining whether ground pepper is genuine and of good quality, the best way consists in ascertaining the amount of piperine contained in the pepper under examination." Thus here, again, no instructions are given, by which the nature of the adulterations practised in each case may be determined, but we are recommended to ascertain the amount of piperine present, and which, when known, tells us nothing about the adulterations of the article, but simply indicates quality; a pepper may be either good or bad, and accordingly contain much or little piperin, and yet be perfectly "genuine." Although the work of Mr. Normandy was published in the year 1850 not a syllable is said about the application of the me-

croscope to the detection of the adulterations of pepper. The last authority to whom we shall refer is Pereira who in the description of piper nigrum as contained in the new edition of his "Materia Medica" and under the head adulteration writes "Sago is said to have been used to adulterate ground white pepper. The microscope would readily dedect the fraud the starch grains of sago, being very much larger than those of pepper from which they also differ in shape. The above paragraph comprises the whole that is said by Dr. Pereira, on the adulteration of pepper. We have now to state that by means of the microscope applied to the elucidation of structural botany we have succeeded in detecting in the most satisfactory and conclusive manner the adulteration of pepper by not less than five different substances namely linseed, mustard-seed wheat-flour pea-flour and ground rice. On Factitions Pepper berries. Some years since it was not uncommon to meet with artificial pepper corns instances of their occurence are mentioned in "Thompson's Annals of Chemstry and also by Accum in the second edition of his celebrated Death in the pot. Thus Accum writes I have examined large packages of both black and white pepper by order of the Excise and have found them to contain about sixteen per cent of this artificial compound. This rpurious pepper is made of Oil cake (the sesidue of the linseed from which the oil has been pressed, common clay and a portion of cayenne pepper formed into a mass and granulated being first pressed through a seive and then rolled in a cask. The period during which this fraud prevailed was probably confined to the time, which expired in 1823, when the duty amounted to no less than 2s. 6d. on a single pound of pepper. It appears. First, that more than half of the peppers purchased previous to the recent convictions were adulterated. Second, that a much less, although still a considerable proportion of the samples procured subsequent to those convictions were likewise adulterated. The present duty on pepper is 6d per pound, and 5 per cent, thereon, which yielded, for the year 1850, no less than £85,526 8s. 1d. We thus perceive how great is the interest of the Government to prevent the adulteration of this article, by which thousands are lost to the Exchequer annually. The sum of £85,526 8s. reduced to sixpences, gives the number of pounds consumed in the year 1850 viz., 1,710,536 pounds. Mr. Culloch estimates the quantity of pepper retained for consumption in the year 1842 at 2,679,624 pounds and the income derived from the duty at only £70,348 3s. 4d. These two statements it is impossible to reconcile, for, if correct upwards of 1,000,000 pounds must have escaped the duty altogether. There were entered for home consumption, in the year 1852, 3,524,502 lbs; in 1853, 3,461,333 lbs: and in the first six months of 1854, 1,656,721 lbs. We believe, that were the duty on pepper still further reduced, the revenue would be found to suffer scarcely at all, and that the increased consumption and lessened inducement to adulteration which would exist, would cause the sum fully to equal, if it did not exceed, the present amount.—*Food and its Adulterations, p.* 42. Pepper is a regular crop on the Western Coast, of India in, Coorg, Mysore, Canara and Travancore.

The following varieties were examined.

Black Pepper.	Long, Pepper.
White Pepper,	Cubebs.

The two first are the same substance, but the white pepper is less pungent than the black, from which the wrinkled covering has been removed by bleaching, which improves the colour, but deteriorates the quality. The quantity of black pepper exported is immense, that of Malabar is the best.—*M. E. J. R.*

Pliny, the naturalist, states that the price of pepper in the market of Rome in his time was, in English money, 9s. 4d. a pound, and thus we have the price of pepper at least 1,774 years ago. The pepper alluded to must have been the produce of Malabar, the nearest part of India to Europe that produced the article, and its prime cost could not have exceeded the present one, or about 2d. a pound. It would most probably have come to Europe by crossing the Indian and Arabian oceans, with the easterly monsoon, sailing up the Red Sea, crossing the desert, dropping down the Nile, and making its way along the Mediterranean by two-thirds of its whole length. This voyage, which in our times can be performed in a month, most probably then took eighteen. Transit and customs duties must have been paid over and over again, and there must have been plenty of extortion. All this will explain how pepper could not be sold in the Roman market under fifty-six times its prime cost. Immediately previous to the discovery of the route to India by the Cape of Good Hope, we find that the price of pepper in the markets of Europe had fallen to 6s. a

pound, or 3s. 4d. less than in the time of Pliny. What probably contributed to this fall, was the superior skill in navigation of the now converted Arabs, and the extension of their commerce to the islands of the Eastern Archipelago, which abounded in pepper. After the great discovery of Vasco de Gama, the price of pepper fell to about 1s. 3d. a pound, a fall of 8s. 1d. from that of the time of Pliny, and of 4s 9d. from that of the Mahommedan Arabs, Turks, and Venetians.

In 1826, 14,000,000 lbs. of pepper were imported into the United Kingdom, of which about 6,500,000 were re-exported. In 1841, 15,000,000 lbs. were imported, of which 6,500,000 where reshipped to other countries. The home consumption, it will be seen, now raveages about 3,250,000 lbs :—

	Imports. lbs.	Home consumption. lbs.
1845	9,852,984	3,209,718
1846	5,906,586	3,299,955
1847	4,669,930	2,966,022
1848	8,125,545	3,185,337
1849	4,796,042	3,257,911
1850	8,028,319	3,170,883
1851	3,996,496	3,303,403
1852	6,641,699	3,524,501

The following return shows the number of bags of pepper imported into the United Kingdom, with the quantity retained for home consumption :—

	Imports.		Retained for home consumption.	
	Black. bags.	White. bags.	Black. bags.	White. bags.
1843	37,840	3,861	21,163	2,257
1844	60,705	2,123	23,525	2,122
1845	80,600	3,208	30,294	2,861
1847	37,194	1,236	28,768	2,654
1848	65,518	3,042	31,665	2,950
1849	43,651	2,616	32,246	3,859

—*Simmonds.*

(6184) PEPPER, LONG. CHAVICA ROXburghii.

Dar-Filfil, ARAB.	Chabi jawa, JAV,
Tipili, CYNG.	Piper Longum, LAT.
Poivre long, FR.	Tabee, MAL,
Lange Pfeffer, GER.	Filfill-i-daraz. PERS.
Pepeelee Guz. HIND.	Tipili, TAM.
Pippali, Krishna SANS.	Pipuloo, TEL.
Pimenta larga, SP.	Pipel. DUK.
Pepe lungo, IT.	

This species of pepper is the produce of a perennial plant (*Piper longum*), a native of Bengal, Siam &c. The fruit is hottest in its immature state, and is therefore gathered whilst green, and dried in the sun. It is met with in entire spikes about an inch long, possessing a darkish brown, or gray colour. It has a weak aromatic odour, an intensely fiery, and pungent taste, and its properties correspond closely with those of black pepper.—*Faulkner.*

(6185) PEPPER ROOT.

Filfel-Mooch, ARAB.	Granthika, Pippali-Mula, SANS.
Pepeelee-Mool, GUZ. and HIND.	Tipili mooluin, TAM.

The root of the long-pepper is a favourite medicine of the Hindoos; it possess the virtues of the berry, but in a weaker degree, and is prescribed by them in cases of palsy, tetanus, and apoplexy. The long pepper is produced in abundance in many parts of Upper, as well as Lower Hindoostan.—*Ainslie.* Pepper root is procurable in most Indian bazars.

(6186) PEPPER, WILD. Filfil burree. the fruits of several species of Vitex.—*Ben. Ph.* 230.

(6187) PEPPERMINT. MENTHA PIPERITA. An aromatic herb, raised from seed. This plant might be grown for distillation on the hills, and become a valuable article of commerce : grows freely on the plains.—*Jaffrey.*

(6188) PERCIDÆ, or *Percoides* of Cuvier, a family of Acanthopterygious Fishes, of which the Common Perch may be regarded as the type. They have the body covered with scales whose outer surface is more or less rough, and the free margins of which are denticulated. The flesh of these fishes is generally well-flavoured and wholesome. They inhabit both salt and fresh water. The first division of the Percoides, according to Cuvier, comprises all those species which have the ventral fins placed under the pectorals, five soft rays to the pectoral fins, seven branchiostegous rays, and two dorsal fins. This section includes the following genera :—

(6189) *Perca* proper, in which the pre-operculum is denticulated ; the operculum is produced behind into a flattened spine ; the infraorbitals are obscurely denticulated, and the tongue is smooth. The Common Perch (*Perca fluviatilis* of Linnæus) is the best example. It is a common fish in the fresh-waters of Great Britain. Closely allied to this is the *P. Italica* of Cuvier and Valenciennes, a species found in tolerable abundance in some parts of Italy ; it differs from the *Perca fluviatilis* in being of a shorter and deeper form, and is destitute of the black bands. Several true perches are found in North America ; species have also been discovered in Java and New Zealand : it is highly probable therefore, from the extensive geographical range of the Perches proper thus exhibited, that very many species still remain to be discovered.

(6190) *Labrax* (Cuv. and Val.) differs chiefly from the true Perches in having the infra orbitals destitute of denticulations as well as the subopercular ; the operculum (which, as well as the preoperculum, is entirely covered with scales) has two spines on the posterior part, and the tongue is furnished with minute teeth. [LABRAX.]

(6191) *Lates* (Cuv. and Val.), a genus also closely allied to *Perca* proper, in fact differs only in having the infra orbitals more deeply denticu-

lated as well as the humerals; large spines are observable on the angle of the preoperculum; the anterior dorsal is shorter and higher than in the Perch; the tongue is smooth, as in the last-mentioned fish. The fishes of this sub-genus are usually of large size, good eating, and are chiefly found in the rivers in the warmer parts of the Old World.

4. *Centropomus* (Lacep.).

5. *Leucioperca* (Cuv and Val.).

6. *Huro* (Cuv. and Val.).

7. *Etelis* (Cuv. and. Val.)—Only one species of *Etelis* is known; its body is elongated, the muzzle is rather obtuse, the eyes very large, and the outer rays of the tail-fin are elongated. This fish (the *E. carbunculus*, Cuv. and Val.) is remarkable for its brilliant red colour, and is adorned with longitudinal golden stripes. It is found in the region of the Seychelle Islands, north of Madagascar.

8. *Niphon* (Cuv. and Val.).

9. *Enoplosus* (Lacepede).

10. *Diploprion* (Kuhl and Van Hasselt), like the two preceding genera, contains but one species (*Dip'oprion bifasciatum* of the authors just quoted). It is found off the coast of Java.

11. *Apogon* (Lacepede).

12. *Cheilodipterus* (Lacepede).

13. *Pomatomus* (Cuv. and Val.).—Only one species of this genus is known, the *Pomatomus telescopium* of Risso, and this is said to be exceedingly rare, living, it appears, in very deep water.

14. *Ambassis* (Cuv. and Val.).—In the form of the body it approaches the common perch. It is the *A. Commersonii* (Cuv and Val.): a second species is found off the Malabar coast, and there are several in the Indian seas, most of which are described by Hamilton in his 'Account of the Fishes found in the River Ganges and its Branches,' under the generic name *Chanda*.

15. *Aspro* (Cuv. and Val.).

16. *Grammistes* (Cuv. and Val.)—The *G. orientalis* (Cuv. and Val.) is of a small size; its colour is deep brown, and the head and body are adorned with numerous longitudinal white lines; the number of these lines, it would appear, varies in different individuals. It inhabits the Indian seas.

The second division comprises those species in which the first or spinous dorsal is united with the second or soft-rayed dorsal, so as to form one continuous fin, and is composed chiefly of the great genus *Sternarus*. The third division embraces those Percoid Fishes which differ from the preceding in having less than seven branchiostegous rays.

1. *Myripristis* (Cuv. and Val.).

2. *Holocentrum* (Cuv. and Val.).

3. *Beryx* (Cuv. and Val.).

In the fifth division of Percoid Fishes the ventral fins are placed in advance of the pectorals. It contains the genera *Trachinus*, *Percis*, *Pinguipes*, *Percophis*, and *Uranoscopus*. In the sixth and last division the ventral fins are placed behind the pectorals. It comprises the genera *Sphyræna*, *Parulepis*, and *Polynemus*.

(6192) PERDICIDÆ, the name of a family, or, according to some, a sub-family of *Tetraonidæ*: in the latter case the form should be *Perdicinæ*.

The genus *Perdix*, Briss., in Mr. Swainson's arrangement, is made to contain the sub-genera *Perdix* (Partridges); *Choetopus* (Francolins); *Coturnix* (Quails); *Ptilopachus*, Sw.; and *Ortyx*, Stephens.

The *Perdicinæ*, according to Mr. G. R. Gray's arrangement, form the first sub-family of the *Tetraonidæ*, and consist of the following genera:—*Ithaginis*, Wagler; *Francolinus*, Briss.; *Perdix*, Lath.; *Starna*, Bonap.; *Lerwa*, Hodgs.; *Arborophila*, Hodgs.; *Colurnix*, Briss.; *Ptilopachus*, Swains.; *Lipornyx*, Vieill. *Ortyx*, Stephens; *Lophortyx*, Bonap.; *Callipepla*, Wagler; *Odontophorus*, Vieill.; and *Tetraogallus* (*Lophophorus* of Jardine and Selby), J. E. Gray. The birds of this group are widely spread over the earth, no quarter of the globe being without some of the family, all of which are more or less esteemed as affording a nutritious and sapid food to man. The ardent temperament of the Partridge has been the theme of many writers on natural history from Pliny downwards, and the parental affection of the female for her young seems to be not less strong than the sexual ardour of the male. The rough nest, which is placed on the ground in corn-fields, meadows, &c., contains from twelve to eighteen or even twenty eggs of a greenish ash-colour; and the hen sits so close that her head not unfrequently falls before the scythe of the mower, as represented in one of Bewick's admirable cuts.

(6193) *Francolinus*. The species occur on the old continent and its islands. The form occurs in Europe, Asia, and Africa. The Francolins are forest birds, perch on trees, and feed on seeds, bulbs, &c. The species is widely distributed. In Europe its habitat appears to be exclusively confined to the southern regions, as Sicily, Malta, and the Neapolitan territories, but it is also found in the north of Africa, and over the greater portion of the Asiatic continent, and in the Himalaya Mountains.

(6194) *Francolinus Ponticerianus*, *Perdix Ponticeriana* of Latham, Ferruginous and Gray Francolin, appears to be confined to Asia. This species, according to Colonel Sykes, is the Teetur of the Mahrattas, and is called a partridge in the Dukhun (Deccan), where it is the most common of birds, frequenting gardens and cultivated lands. The Colonel describes the irides as intense red-brown, and its length, inclusive of the tail (which is 3 inches 6-10ths) as 14 inches. He states that it is not met with in the Ghauts, unless in well

cultivated valleys, and not at all on the mountains. It roosts on trees, in which situation the Colonel, on more than one occasion, shot them during the day-time; but this was a rare occurrence. ('Zool. Proc.,' 1832).

Another Francolin, *Francolinus spadiceus*, measuring with the tail (which is 5 inches) 14 inches 7-10ths, is very common in the thick brushwood of the Ghauts. Colonel Sykes had both sexes alive in his possession for some time, and has no doubt that they might be successfully introduced into Europe. He describes them as excellent eating, and says that they rarely take wing or perch The male has a harshtrysillabic call, Kok-[illegible], whence the Mahrattan name Koku-tree. The female in confinement uttered little notes, like the twittering of a chicken. A male in Colonel Sykes's collection had three large spurs on one leg and two on the other. ('Zool. Proc.,' 1832.)

(6195) *Coturnix* (Brisson).—The species of this genus are vernacularly known as Quails. They are found in the Old World and Australia only.

C. dactylisonans, Mayer (*Tetrao Coturnix*, Linn. *Perdix Coturnix*, Latham). This well known bird, a description of which would be superfluous, seems to be the Ὄρτυξ of Aristotle, who mentions the bird repeatedly in such terms as to its habits and migration as to leave little or no doubt on the point; and the *Coturnix* of the Romans. It is the Quaglia of the Italians; Caille of the French; Wachtel of the Germans. Sofliar and Rhine of the Welsh; and Quail of the English; Lohah and Lowa of the Mahrattas. Col. Sykes, in his valuable paper 'On the Quails and Hemipodii of India' ('Zool. Trans,' vol. ii.), in which he states that he found the tongue and the cæca of birds to be of considerable importance in indicating affinities or dissimilarities between genera, notices *C. dactylisonans*, *C. textilis*, *C. erythroryncha*, *C. Argoondah*, and *C. Pentah*.

(6196) *Coturnix Argondah*, the Rock-Quail of Dukhun (Deccan), "is readily distinguished by the numerous transverse narrow black bars upon the breast; but the young males and the females want these bars, and vary so much in the markings on the back, that with those disposed to manufacture species from plumage alone, the eleven specimens before me from Dukhun would furnish at least four new species." (Sykes.) The flesh is perfectly white. Col. Sykes says that this is the species used for Quail fights by the natives, and not *C. dactylisonans* or *C. textilis*.

(6197) *Hemipodius*, Temm.; *Turnix*, Bonn.; *Tridactylus*, Lacep.; and *Ortygis*, Ill. The species are found in Europe, Asia, Africa, Austr alia, and Oceania. Colonel Sykes, in his paper above alluded to, describes three species—*H. pugnax*, *H. Taigoor*, and *H. Dussumieri*. In the stomach of the first he found the remains of black ants, minute coleopterous insects, and grass-seeds; the flesh was in brown and white layers, and the Colonel states that its pugnacious qualities are quite unknown in Dukhun, and even in Java. They were frequently in pairs, but mostly solitary, haunting cultivated lands, especially Chillie fields (*Capsicum annuum*). Their flight he describes as lazy and short, nor are they readily put on the wing. He adds that the Zoological Society had a specimen from Madras, and that it would appear therefore to have an extended geographical range over the Eastern islands and India. We shall presently notice *H. Taigoor*.

(6198) *Hemipodius Dussumieri*, the Button-Quail of European sportsmen in India, he says that it affects short thick grass and fields of pulse of *Dolichos biflorus*, *Phaseolus Max*, and *Ervum Lens*. He never found the bird otherwise than solitary, and says that it is so difficult to flush, that it not unfrequently rises from beneath the feet; and when on the wing, its flight is so abrupt, angular, and short, that it is generally down before the gun is well up to the shoulder.

H. Taigoor is chestnut above, feathers margined with straw colour, and with undulated bands of black; wing coverts straw-colour banded with black; quills brown, chin and throat white, breast banded with black and white, belly and vent dilute ferruginous, irides pale-yellow, bill blackish. Length of the body 4 inches 8-10ths, of the tail 1 inch 7-10ths. (Sykes.) Dr. Smith remarks that in the Museum of the Army Medical Department at Fort Pitt, Chatham, there are the male and female of an Indian species of *Hemipodius* very closely resembling the Doctor's *Hemipodius Lepurana*. They differ however, he observes, in so many minor points, that he feels disposed to regard them as belonging to a distinct species. In the Catalogue of the Fort Pitt Collection, Dr. Smith has named this Asiatic species *Hemipodius Sykesii*, in honour of Colonel Sykes, who has added so much to our knowledge of the zoology of India. ('Illustrations of the Zoology of South Africa.)' Before we quit this sketch of the Partridges and Quails, we must notice two forms which particularly demand attention, as leading to other types. The first of these, the Sanguine Partridge (*Perdix cruenta*, Pl. Col., 332), appears to bear the following generic names: *Ithaginis*, Wagler *Plectrophorus*, J. E. Gray, and *Ptilopachus*, Sw. It is described as a pheasant in 'Linn. Trans.' vol. xiii., and may be considered as uniting the Partridges with the Pheasants and the Polyplectrons, like the latter of which, it has often more than one spur upon the tarsi. The plumage of this bird, which is a native of Nepaul, is brilliant, and the feathers of the head and neck are elongated.

The *P. Lerwa*, described by Mr. Hodgson ('Zool. Proc.,' 1833) inhabits, according to that gentleman, the northern region of Ne-

paul, and forms by its half-plumed tarsi a sort of link between the Partridges and the Grouse, the latter of which it resembles in its habits. It is found close to the permanent snows, among rocks and low brush-wood, feeding upon aromatic buds, leaves, and small insects. The plumage is black, lineated transversely with white and chestnut; the breast is brown. Mr Hodgson remarks that the great comparative expanse of the wing, the diminution of its rounded form by the second quill-feather being the longest, the increased length and strength of the tail, and the extent of the feathering of the tarsi, are very remarkable characters, which give to this species a strong interest,—*Eng. Cyc.*

(6199) PERGULARIA ODORATISSIMA, Asclepiaceæ. Fragrant Pergularia. This is a creeper with a climbing woody stem, cracked bark, flowers yellow, and very fragrant, well adapted for covering trellis work.—*Jaffrey.*

In the gardens in Maulmain, this fragrant flowered creeper is often cultivated. *Mason* Pergularia pallida, 585. is given by Wight.

(6200) PERINSIRAGUM. Anethum Fæniculum Linn. Sweet Fennel

Perinsiragum, Tam.	Souf, Duk.
Variari, Guz.	

Perinsiragum is a name sometimes also given to Aniseed.—*Ainslie's Mat. Med. p.* 267.

(6201) PERIPLOCA SYLVESTRIS. Willd: Root of the Periploca of the woods.

Sirroo Coorinja vayr, Tam.

This bitter root is supposed by the Native Practitioners to possess virtues in cases of snake bite. Internally it is prescribed in decoction and the powder is applied to the part that is bitten. The plant of which this is the root is called by the Cyngalese Binnuga, the root itself they suppose to possess virtues similar to our Ipecacuan. —*Ains. Mat. Med. p.* 114.

(6202) PERISTROPHE LANCEOLARIA, Acanthaceæ. Peristrophe Speciosa, Vide Justicia.

(6203) PERISTROPHE MONTANA.

(6204) PERISTYLUS. This elegant terrestrial Tenasserim orchid with snowy blossoms is occasionally seen. *Mason.* Wight, in Icones, gives Peristylus exilis, 1698; Lawii, 1695; plantagineus, 921; Richardianus, 1697; robustior, 1699; spiralis, 1696.

(6205) PERRY. A fermented liquor made from pears, in the same manner as cider is from apples. It is chiefly made in Worcestershire.

(6206) PERSEA, a genus of Plants belonging to the natural order *Lauraceæ. P. gratissima* is the Avocado Pear of the West Indies, and receives its name in consequence of the resemblance in form between its fruit and that of a European pear. The plant which bears it is a tree about the size of an apple-tree; the leaves are oblong, veiny, and the flowers small, and of a greenish-yellow colour. The fruit is the size of a large pear, and is regarded as one of the best produced in the West India Islands. In the inside it is yellow, and contains a kernel inclosed in a soft rind. In taste it is said to resemble the peach, but to be much more agreeable, though not so sweet. It is sometimes eaten with pepper and salt, but more frequently with a little sugar and lime-juice. Three varieties are mentioned, the red, the purple, and the green.—*Eng. Cyc.* Wight gives; Persea gratissima, 1823.

(6207) PERSIAN. A silken fabric of various colours, and exceedingly flimsey in its texture. It is chiefly used in lining.—*Faulkner.*

(6208) PERSOONIA. Proteaceæ. The Dele, the Embothrium, the Hakea, Banksia, and Persoonia, are interesting plants introduced from the Cape and New South Wales, the species being chiefly confined to the southern hemisphere. They are handsome green shrubs, and prized by gardeners for the neatness of their appearance and beauty.—*Riddell.*

(6209) PERUVIAN BARK, Cinchona Bark, Cascarilla Bark. (so named in America). A celebrated medicine obtained from a genius of trees (*Cinchona*), confined to the lofty Cordilleras of the Andes in South America, and well known for its febrifuge properties. There are many varieties, and as mixtures and adulterations are very common, great experience is requisite to be able to select the finer kinds. Four sorts are distinguished by British druggists, under the appellations of *Crown* bark, *Gray* bark, *Yellow* bark, and *Red* bark.—*Faulkner.*

(6210) PESSALOO. PHASEOLUS RADIATUS.

Pessaloo, Tel.	Haree moong, Hind.
Pucha payaroo, Tam.	

(6211) PETREA. Verbenaceæ. This is a climbing plant with dark shining green leaves, and beautiful lilac or purple flowers hanging in racemes. It is a native of South America, and only requires to be regularly watered, and grown in a good garden soil, to cause it to extend itself over an immense space, its long slender whip-like shoots should be lopped down, to make it throw out branches, at the end of which the flowers appear in most elegant festoons towards the close of the cold season. It is easily propagated by layers.

(6212) PETROLEUM. BITUMEN. Rock. Oil.

Mantylum, Tam.	Minna tanna, Malay.
Mattee ka tail, Duk. and Hind.	Boomie tylum, Tel.
Neft, Arab.	Japoo, Sumatran.
	Kesoso no abra, Japanese.

This substance is called earth oil by the English in India, and is brought to this country from Bussorah from the Sooloo island, or from the kingdom of Ava: it is also found in Japan and Sumatra.—*Ainslie's Mat. Med., page* 31. Petroleum is officinal but little used by the Hakeems at Lahore. Petroleum Punjabinum is a product of the hills on the west side of the Indus, called Tukle Reisar near Banu, and Tank, procurable in the bazar of Dhera Ismail Khan. It is of a reddish color, lumped as spirit at Lahore. I used this and also another sort, which I had from Bombay.—*Dr. Honigberger, p.* 322.

Petroleum, as its name indicates, is an oil-like exudation from rocks, which has been employed in medicine from the earliest times, though little used now. It is very abundantly diffused, and in other forms, as of Asphalte, Naptha, &c. Besides in Barbadoes and Trinidad, Petroleum is found floating on some springs of water in this country, as at Colebrooke Dale, &c., in many parts of Europe, also at Baku on the shores of the Caspian, and very abundantly at Ranangoong, or Earth-oil Creek, on the banks of the Irrawaddy. Col. Symes describes the wells as about 500 in number, and that upwards of 400,000 hogsheads are taken away in boats. It may readily be obtained by digging into the sand in warm weather. This was examined by Drs. Christison and Gregory, who found in it Paraffin, Eupion, which Reichenbach met with among the products of the destructive distillation of wood; whence they infer that "Rangoon Petroleum is the product of the destructive distillation of vegetable matter," probably from subterraneous causes now in operation. Petroleum has the consistence of treacle; reddish-brown or black colour, with a bituminous taste; floats on water, in which it is insoluble; burns with a dense black smoke, leaving a carbonaceous residuum. Acids, alkalis, and Rectified Spirit have little effect on it; Ether and both Volatile and Fixed Oils dissolve it. Exposed to the air, it hardens into Asphalte: if exposed to heat, a yellowish coloured liquid distils over, which resembles the Naphtha obtained in making Coal-gas. Both are free from Oxygen, and therefore used for preserving Potassium and dissolving Caoutchouc.

Action. Uses. Stimulant; has been recommended externally in Rheumatism and in Cutaneous affections; internally as a Vermifuge. The Rangoon is probably as good, if not better, than other kinds. *Royle.*—Petroleum was collected in a recent survey of Chedooba, on the Arracan coast, and is found abundantly in the Burman Empire. The town of Rai-nan-ghong, is the centre of a small district, in which there are some hundred petroleum wells, (more than five hundred, *Mason*) in full activity. The district in which they are situated consists of a sandy loam, resting upon alternate strata of sandstone and indurated clay: under these is a layer of pale, blue, argillaceous schist, of considerable thickness, impregnated with petroleum; and resting upon coal. The petroleum flows into the well when it is sunk a few feet into the schist, and when it begins to fail the well is deepened. It is remarkable that no water ever penetrates into these wells. The annual quantity of petroleum produced by the district, exceeds 400,000 hhds. The uses of petroleum, where it abounds are very important. It serves the lower classes, instead of oil, for lamps, and mixed with earth or ashes, answers the purposes of fuel. A composition of petroleum and resin is an excellent material for covering wood work and for paying the bottoms of ships and boats, as it protects the timber from the attacks of worms and insects. When rectified by distillation, it affords naphtha.—*Tomlinson.*

Asphaltum, or *black Bitumen*, (Zift-roomie, *Pers.*) is a deep black, pitch-like solid; hard, softens at 150°, and melts above that; highly inflammable, believed to be the result of the natural distillation of petroleum. It is produced in abundance in Barbadoes and Mesopotamia. It is a valuable lacquer for the protection of iron or tinned iron vessels. A lump rubbed over the Asphalt-heated metal coats it with a hard adhesive brilliant coat, which resists most of the common corrosive agents.—*O'Shaughnessy, page* 693. See BITUMEN: also NAPHTHA: also ROCK OIL.

(6213) PETROSELINUM, (Πετροσέλινον, which means Rock Parsley, rock being the habitat of the species), a genus of Plants belonging to the natural order *Umbelliferæ.*—*Eng. Cyc.*

(6214) PTEROSPERMUM INDICUM. KIABOOCA. A handsome specimen of this ornamental wood was exhibited by Dr. Sanderson, it is imported from Singapore It is beautifully mottled, of different tints, evidently produced by excrescences from the tree. The wood is chiefly used for inlaying or for making desks, snuff boxes, puzzles, &c.—these are exhibited by the Madras Local Committee.—*M.E.J.R.*

(6215) PETROSELINUM SATIVUM, Common Parsley, has tripinnate shining leaves; leaflets of the lower leaves ovate-cuneate, trifid, and toothed; of the upper leaves ternate, lanceolate, entire. It grows wild on rocks and old walls, and is extensively cultivated—*Eng. Cyc.*

(6216) PETUNIA. SOLANACEÆ. This is an ornamental genus of plants, and easy of cultivation, the colours are white, purple, crimson and purple, or rose coloured; they grow readily from seed either in the rains, or cold weather, and form pretty border flowers.—*Riddell.*

(6217) PETUNTZE, the Chinese name for a white earth used with Kaolin in the manufacture of porcelain. It is stated that while [KAOLIN] is derived from the decomposition of the felspar of granitic rocks, the latter, or Petuntze, is the same mineral which has not suffered decomposition, and that on account of its fusibility it is employed in glazing the porcelain.—*Eng. Cyc.*

(6218) PEWTER.

Rissa, ARAB.	Stagno, IT.
Etain, FR.	Olowo, RUS.
Zinn, Zinngeisserzinn, GER.	Estano, Peltre. SP.

A factitious metal made of four parts of tin, and one of lead; but a finer kind is said to consist of tin mixed only with a little antimony and Copper. It is used in making plates, dishes, spoons, and such other domestic articles. *Faulkner.*

(6219) PHACELIA. *Hydrophylleæ.*—Hardy plants, flourishing in any common soil; the flowers are curious, from the manner in which they slowly unroll themselves. Some are perennials, and others biennials; the flowers are chiefly pink and blue coloured—propagated from seed.—*Riddell.*

(6220) PHAETON, Linnæus, a genus of Palmipede Birds, placed by some ornithologists among the *Pelecanidæ*, and by others among the *Laridæ*. This genus, so well known to navigators as the harbinger of the tropics, is distinguished at once by the two long slender tail-feathers, which have obtained for the species, of which two only are recorded, the French name of Paille-en-Queue, and from the English the Boatswain. Their length of wing and comparative feeble feet proclaim them formed for flight, and they are accordingly swift and untired on the wing, disporting in the air far at sea; and when on land (to which they do not often retreat for any length of time together, except at the period of nidification), perching on rocks and trees. They rarely quit the torrid zone and its neighbourhood. M. Lesson remarks that the two species form a well-defined artificial and purely geographical group. Their habitual domicile in the torrid zone does not separate them from the land; and they can reach, as they do nearly every night, the isles and lofty rocks that serves them as a place of refuge. Nevertheless M. Lesson met with them so often in sea-tracts entirely devoid of land, and heard them so often above his head in the calms and fine tropical nights, that he thinks they should be considered as oceanic birds. The same author remarks that sudden squalls or hurricanes, so frequent in the equatorial zone, often sweep these birds beyond their natural limits; and he thus accounts for seeing them, as he many times did, in 30° S. lat. The Common Tropic-Bird (*Phaeton æthereus,*) he says, "semble être confine dans l'ocean Atlantique, et s'arreter dans les mers de l'Inde." The other species (*Phaeton phœnicurus*), he remarks, appears to belong more particularly to the great equinoctial ocean. Nevertheless, he adds, that both species exist in nearly equal numbers at the islands of Mauritius and Bourbon. He describes the flight of these birds as calm, quiet, and composed of frequent strokes of the wing, sometimes interrupted by a sort of falls or sudden movements.—*Eng. Cyc.*

(6221) PHAETON ŒTHEREUS, Linn., the Tropic Bird of Catesby, Sloane, and others. The following is Catesby's description:—"This bird is about the size of a partridge, and has very long wings; the bill is red, with an angle under the lower mandible, like those of the gull kind, of which it is a species; the eyes are encompassed with black, which ends in a point towards the back of the head; three or four of the larger quill-feathers towards their ends are black tipped with white; all the rest of the bird is white, except the back, which is variegated with curved lines of black; the legs and feet are of a vermilion red; the toes are webbed; the tail consists of two long straight narrow feathers almost of equal breadth from their quills to their points. "These birds," says the same author, "are rarely seen but between the tropics at the remotest distance from land. Their name seems to imply the limits of their abode; and though they are seldom seen but a few degrees north or south of either tropic, yet one of their breeding-places is almost nine degrees from the northern tropic, namely, at Bermudas; where, from the high rocks that environ those islands, I have shot them at the time of their breeding; but those cliffs being inaccessible, prevented my seeing their nests and eggs. They breed also in great numbers on some little islands at the east end of Porto Rico. There was a specimen in Tradescant's Museum.—*Eng. Cyc.*

(6222) PHAETON PHŒNICURUS. Length from the extremity of the bill to the origin of the tail, 13 inches 6 lines; of the bill from the point to the commissure, 3 inches 8 lines; breadth across the expanded wings, 31 inches. Length of the tail, 5 inches; of one lengthened tail-feather (brin) taken at the extremity of the tail, 7 inches 6 lines; of the second and smaller long tail-feather (brin) taken from its origin, 6 inches. Ten tail-feathers, without counting the long one, which at its origin is enlarged like the other feathers; the tail forms a fan. Feet, taken from the leg to the toes, 3 inches. Legs white, with a light bluish tint in some places; webs partly black, that between the hind toepale flesh-colour slightly glazed with white. Bill red, denticulated; nostrils near the origin of the bill, rather large, presenting forwards a canal which scarcely extends to the middle of its length, and of a blackish tint. Plumage satin-white; in front of the eyes a large brown spot. The anal feathers present a great black spot in their centre, as well as some

of the feathers which approach the body. The long tail-feathers (brins) are red, the smallest being of the deepest hue. The shafts of the greater quill-feathers, of the tail feathers, and the long tail-feathers (brins), are black, but towards the extremity they are white. ('Manuel.') —*Eng. Cyc.*

(6223) PHALLUS ESCULENTUS Morilla (Fungus) Morels are imported from the hills into Lahore but are very little used by the natives; and the English use them, not medicinally, but for culinary purposes. The Morels which are brought from the Hazara country, are large.—*Honig. p.* 323.

(6224) PHARBITIS, a genus of Plants belonging to the natural order *Convolvulaceæ*. It has 5 sepals a campanulate funnel-shaped corolla, 1 style, a capitate granular stigma, a 3-celled, rarely 4-celled ovary, and 2-seeded cells. The species of this genus are easily distinguished from others of the same order. They are mostly climbing American herbs, usually beset with retrograde hairs.—*Eng. Cyc.*

(6225) PHARBITIS CÆRULEA. Wall. Syn. IPOMÆA CÆRULEA. *Kon. Rox. Fl. Ind.* i. p. 501. Nearly allied to Pharbitis Nil; but probably a distinct species.

Hub ul nil, ARAB.	Kaladana and Mirchai, HIND. and BENG.

Common all over the tropics every where, and in India even ascends the mountains to 5000 feet elevation.—*O'Shaughnessy, p.* 505. Its *Seeds*, called Hub ul nil, Kaladana, Mirchai, are black, angular, weighing on an average ½ a grain each, in powder of a grey colour, of sweetish, and subsequently rather acrid taste, and heavy smell. On analysis yields resin, gum, starch, fixed bland oil, fibre, and colouring matter. The powdered seeds in doses of 30 to 40 grains act as a quick, safe, and pleasant cathartic. Dr. O'Shaughnessy made this seed the subject of numerous experiments. In 100 cases in which it was given under his direction in the Police Hospital of Calcutta it proved purgative in 94, occasioned vomiting in 5, and griping but in 15, and produced on an average 5 stools within 2½ hours; the operation generally commenced in an hour, and in these experiments was never delayed beyond four hours. The alcoholic extract, which consists of resin and oil, is deep brown, ductile, of excellent pillular consistence, and keeps for several months. In 10 grain doses it produces all the effects of jalap with certainty and speed; the taste is scarcely perceptible. Dr. Chapman has used it in several cases at the General Hospital, and reported on it most favourably to the Medical Board; Dr. Leckie of Bhagulpore, Dr. Green of Howrah, Drs. Martin, Stewart and Goodeve, have given similar accounts of its efficacy. The seeds sell for four seers (8. lbs.) for the rupee; these will yield from 15 to 20 per 100 of alcoholic extract, and the whole of the alcohol may be recovered by distillation. We have thus a remedy of unparalleled cheapness, perfectly equal to jalap as a cathartic, superior to it in portability, and flavour, and occurring in all parts of India. We are consequently independent in every respect of the South American article.—*O'Shaughnessy. page* 505—6.

(6226) PHARBITIS HISPIDA. CONVOLVULACEÆ. The Pale blue large flowered Pharbitis.—*Riddell.*

(6227) PHARBITIS NIL, has twining annual round hairy branches, and stem stalked; 3-lobed downy leaves; axillary peduncles, from 2- to 3-flowered. The flowers large, of a beautiful light bright bluecolour; the capsule is much shorter than the calyx, smooth, 3-celled, with two seeds in each cell. The seeds are sold in the apothecaries' shops of Calcutta under the name of 'Kala Dana,' and are said to act as a purgative and an effectual speedy carthartic. They are roasted like coffee, powdered, and administered in doses of from 30 to 40 grains. It is a native of the tropics in every part, and in the South Sea Islands. There are about 15 species of this genus, but the one described is the only one of use.—*Lind. Flor. Med.*—*Eng. Cyc.*

(6228) PHARID-BUTI. A mucilaginous plant found at Ajmeer: used in sherbets.—*Gen. Med. Top. p.* 142.

(6229) PHARNACEUM MOLLUGO: LADIES BED STREW.

Ghimasag, HIND.

Wild in gardens during the rains, sometimes used as a pot herb.—*Gen. Med. Top. p* 188.

(6230) PHASEOLUS, a genus of Plants of the tribe *Phaseoleæ*, in the natural order *Leguminosæ*. The name is said to be derived from Phaselus, a little boat, which the pods are thought to resemble; but it may be that the meaning of 'boat' is derived from the resemblance of a boat to the form of a bean. Two species are very well known in England, *P. vulgaris*, the Common Kidney Bean, and *P. multiflorus*, the Scarlet Runner; their unripe pods being much esteemed as legumes, and also for pickling. The ripe seeds are however employed on the continent, and form the Haricots of the French. The genus is however one of which the species are indigenous in tropical parts both of the Old and New World. Several are cultivated in India, and are some of the principal articles of the agriculturist's attention, as the ripe seeds of several species form pulses which are much used by the natives as a portion of their diet, and some of which, like the Kidney Bean, abound in nutritious matter.

Phaseolus is characterised by having a bell-shaped 2-lipped calyx. The corolla is papilionaceous, and has the keel, as well as the diadelphous stamens and the style, spirally twisted.

The legume is compressed or cylindrical, with two valves, and is many-seeded, with more or less conspicuous cellular partitions between the seeds. The hilum of the seeds is oval oblong. The plants are herbaceous or suffrutescent in habit. The leaves are pinnately trifoliate, the leaflets with partial stipules. Racemes axillary. Pedicels usually in pairs, single flowered. Wight, in Icones, gives Phaseolus lunatus, 755; psoraleoides, 249; Pulniensis, 202; rostratus, 34; and trilobus, 94.

(6231) PHASEOLUS ACONITIFOLIUS, Lin.

Tulka, pyre, TAM.	Kooncooma pesuloo, TEL.
Mat, GUZ.	
Moat, DUK. & HIND.	Vasunta, SANS.

This is a small pleasant tasted pulse, much cultivated in the higher provinces of India, where there are two kinds of it.—*Ainslie, page* 246. Moth of the natives, is cultivated in the north-western provinces, and used for feeding cattle.—*Eng. Cyc.* Phaseolus Aconitifolius is culvitated in the Punjab, and for food. Its roots, as well as those of Phaseolus radiatus, are said by Royle, to be narcotic.—*Dr. Honigberger, p.* 323.

(6232) PHASEOLUS AUREUS, or Sona Moong of the Bengalees, is found in a cultivated state in the Bengal presidency, but is not known on the Coromandel Coast. It is sown, like the others, about the end of October or beginning of November, and reaped in February or the beginning of March.—*Eng. Cyc.*

(6233) PHASEOLUS LUNATUS, DUFFIN BEAN.

Bunburbutee, HIND.

Sown in rows the same as other beans, but with a much greater space between; they require very strong sticks for support, and are ready in about six months. No very particular care is necessary.—*Jaffrey.* This is a most valuable bean, much prized by the European inhabitans of India; by some of whom it is preferred to the Windsor bean. It was originally brought to this country from Mauritius and is extremely prolific.—*Ainslie, p.* 240.

(6234) PHASEOLUS LUNATUS. Var. COUNTRY BEAN; DUFFEN BEAN. This is a pleasant tasted bean much cultivated by the Europeans in these provinces whither it was brought some years ago from the Isle of France. —*Ainslie, p.* 239.

(6235) PHASEOLUS MAX. BLACK ULANDOO.

Carpoo Ulandoo, TAM.	Benoo mash, PERS.
Klie Oorood, DUK.	Wooddoo, MAL.
Nulla Woodooloo, also Minomolu, TEL.	Chicuda, CAN.
Mash, ARAB.	Masha, SANS.

This pulse differs but little from the common Ulundoo, except that it is of a darker color, and somewhat larger.—*Ainslie, p.* 237.

The Moong of the natives, and Black Gram of the English, is like *P. Mungo* but distinguished by its black seeds, and is, like it, found in a cultivated state; it takes about the same time to ripen, and yields nearly the same produce.—*Eng. Cyc.*

(6236) PHASEOLUS MULTIFLORUS, the Scarlet Runner, is a native of South America. Both are delicate, and in England cannot be safely planted in the open air till the beginning of May. —*Eng. Cyc.*

(6237) PHASEOLUS MUNGO. MASH.

Woothooloo, TEL.	Woolooathoo, TAM.
Mash, HIND.	

(6238) PHASEOLUS MUNGO, MELANOSPERMUS. BLACK GRAM. Mason says that one of the most common pulses seen in Burmah is the *Phaseolus max*; which is the plant that produces the black gram of India.—*Mason.*

(6239) PHASEOLUS MUNGO.

Moong ka dal, HIND.

Cultivated in the rains wherever the soil will permit.—*Genl. Med. Top. p.* 203.

(6240) PHASEOLUS MUNGO. ULANDOO, Lin.

Ulandoo, TAM.	Hessaru, CAN.
Arad, GUZ.	Moong, MAH.
Oorood, DUK. & HIND.	Danie Masha, SANS.
Wooddooloo, TEL.	

This very pleasant tasted pulse is much prized, dressed in various ways. Phaseolus Mungo, or Moong, is one of the dry leguminous grains of India, which are of great value whenever the periodical rains fail and rice cannot be grown, and famine is the consequence.—*Eng. Cyc.*

Two sorts of this pulse are grown in all parts of Mysore and are exported to Mangalore. It will keep good for about three years if carefully preserved by packing it in parcels. Ordinary price at Bangalore is a Rupee for 7 seers.—*Ainslie, page* 247. *M. E. J. R.*

(6241) PHASEOLUS NANUS. DWARF KIDNEY BEAN.

Frash bean, HIND.

Cultivated. in Ajmere—*Med. Top. p.* 203.

(6242) PHASEOLUS RADIATUS. INDIAN GREEN GRAM, or Rayed kidney Bean.

Putsa pasaloo, TEL.	Harie Moong, DUK.
Harree moong, HIND.	Husaroo, CAN.
Putchee payaroo, TAM.	Harita, SANS.
Mag, GUZ.	Cherroo Poiur, MAL.
Masha, SANS.	Moong, Thikiree, HIND.
Mash Kulia, BENG.	

Roots said to be narcotic by Royle—*O'Shaughaes p.* 317. Phaseolus Radiatus called by the natives Mash and Oorud, is like P. Max and P. Mungo found in a cultivated state, and is the most esteemed of all the Indian leguminous plants. Besides using it as an article of diet, the natives make bread of the meal for some of their religious ceremonies.

(6243) PHASEOLUS RADIATUS (Var.) BLACK GRAM.

Nulla woothnoloo, TEL. | Karooppoodoolooanthoo, TAM.
Kalee Koolter, HIND. | Pauay Pyroo, TAM.

This valuable pulse gets its Tamool name from being nourished by the dews in January and February. It is a variety of the Patchay pyre. —*Ainslie, p.* 243.

(6244) PHASEOLUS TRILOBUS, THREE-LOBED BEAN.

Moojanee, BENG. | Kulaee, HIND.
Trianguli. HIND.

Sown like other native beans. This species of phaseolus, the genus which furnishes the common French bean, grows spontaneously everywhere in the Tenasserim Provinces. Roxburgh describing the species says, that he never found it "*but in its wild state*;" while Voigt is made to say, by a mistake of the printer no doubt, "Cultivated, in which state only it was found by Dr. Roxburgh."—*Mason.* The leaves are said to be tonic and sedative, and are used in cataplasms to weak eyes.—*O'Shaughnessy, p.* 137.

(6245) PHASEOLUS VULGARIS, Kidney-Bean, is said to be a native of India, but Dr. Royle states that seeds were brought to him from Cashmere, and he is therefore inclined to consider that it was introduced into Europe from the most northern parts, such as Cabul and Cashmere and that this accounts for our being able to cultivate it at a lower temperature than other species of the genus.—*Eng. Cyc.*

(6246) PHASIANIDÆ, a family of Rasorial Birds related to the *Pavonidæ*. [PAVONIDÆ.] Mr. G. R. Gray arranges the *Phasianidæ* as the second family of *Rasores*—*Cracidæ* being the first, and he divides the *Phasianidæ* into the subfamilies *Pavoninæ*, *Phasianinæ*, *Gallinæ*, and *Meleagrinæ*. The *Phasianinæ* consists of the genera *Argus*, *Phasianus*. *Syrmaticus*, *Thaumalea*, and *Gennæus*. The *Gallinæ* comprehend the genera *Euplocamus*, *Monaulus*, *Lophophorus*, *Gallus*, and *Tragopan*.

(6247) *Phasianus* (Linn.).—Bill of mean length, strong; upper mandible convex, naked at the base, and with the tip bent downwards. Nostrils basal, lateral, covered with a cartilaginous scale; cheeks and region of the eyes destitute of feathers, and covered with verrucose red skin. Wings short, the first quills equally narrowed towards their tips, the fourth and fifth the longest. Tail long, regularly wedge-shaped, and composed of 18 feathers. Feet having the three anterior toes united by a membrane as far as the first joint, and the hind toe articulated upon the tarsus, which in the male birds is furnished with a horny cone-shaped sharp spur. (Gould.) The type of this genus is generally considered to be *P. Colchicus*, Linn., the Common Pheasant, a bird which, though not originally British, is completely naturalised in that Island, and indeed appears to adapt itself with great facility to most countries where ordinary care is taken to preserve it, and the temperature is not too low for its constitution. The species is too well known to need description. Various instances of the Common Pheasant breeding with other gallinaceous birds are on record. Edwards has figured a bird supposed to have been produced between a pheasant and a turkey. Three or four of these were discovered in the woods near the house of Henry Seymour, Esq., of Handford, Dorsetshire, and he shot one in October 1759, the bird which he sent to Edwards. Mr Yarrell ('British Birds') observes that he has twice been shown birds that were said to be the produce of the Pheasant and the Guinea Fowl, and the evidence of the plumage was in favour of the statement. We have seen such a bird, and its feathers corroborated the allegation that it had been so produced. Hybrids between the Pheasant and Gray Hen are also recorded. Mr. Thompson of Belfast describes ('Magazine of Zoology and Botany') another hybrid shot at Lochnaw, Wigtonshire, where it had been seen several times on the wing by persons who supposed it to be a wild turkey. In the surrounding plantations pheasants and black grouse were numerous; but this individual, which was preserved for Sir Andrew Agnew, Bart., M.P., was the only one of the kind observed. Mr. John Leadbeater, in 1837, exhibited a hybrid between the Pheasant and Black Grouse, shot near Alnwick, at a meeting of the Zoological Society This the Duke of Northumberland presented to the British Museum. The union between the Common Hen and the Cock Pheasant is by no means rare, as is well known to those whose homesteads border upon pheasant preserves. The produce of this union is called a Pero.

Before we leave the True Pheasants we must notice some of the magnificent Indian species, which exhibit such a prodigality of splendour and beauty in their plumage as almost realises the birds which we read of in fairy tales. Such are the well-known gorgeous Gold Pheasant (*Phasianus pictus*, Linn: Genus, *Thaumalea*, Wagler; *Chrysolophus*, J. E. Gray; *Nycthemerus*, Sw.), the equally wellknown delicately-pencilled Silver-Pheasant (*Phasianus Nycthemerus*, Linn.: Genus, *Gennæus*-Wagler; *Nycthemerus*, Sw.; *Euplocomus*, J. E. Gray), and the noble Reeves's Pheasant (*Phasianus reevesii*, Temm.: Genus *Syrmaticus*, Wagler.) The first two of these (natives of China) are common in almost every aviary, and there is no reason why they should not thrive well if turned out in English preserves; the second species has, we believe, been so turned out with success; the last is also found in China, but, as it would seem, on the very confines of the empire. It is very rare in Pekin. Dr. Latham's description was taken from Sir John Anstruther's drawings, and from some writing under them in the Persian language it appeared that the bird

was called Doom dumar, or Long-Tail, and it was found on the snowy mountains of Surinagur. To Mr. Reeves we are indebted for the first individual ever brought alive to Europe. It was a male, and continued to live for some time in the garden in the Regent's Park. Tail-feathers from it were exhibited to the Society in 1831, measuring each about 5 feet 6 inches in length. A second male specimen was also sent to their menagerie by the same liberal donor in 1834. Then there are the beautiful Diard's Pheasant (*Phasianus versicolor*, Vieill.) which haunts the Japanese woods, and exhibits the manners and habits of our Common Pheasant; the rare and elegant Sommering's Pheasant (*P. Sœmmeringii*, Temm.), also a native of Japan. We should also call the reader's attention to the beautiful *P. Staceii* (figured and described by Mr. Gould in his 'Century') as one of the True Pheasants and to *P. Pucrasia* and *P. albocristatus*, also there figured. *Pucrasia* appears to lead the way from the True Pheasants to the *Lophophori*; and *P. albo-cristatus* to be an *Euplocamus*, which, even more immediately than *E. ignitus*, forms a transition from the genus *Phasianus* to the genus *Gallus*. The Argus Pheasant, which is not a species of *Phasianus*, has been brought alive to this country, and a specimen is now in the Gardens of the Zoological Society of London in the Regent's Park.

(6248) *Euplocamus* (Temm.).—Sir George Staunton, in his 'Embassy to China,' first made this highly-interesting form known to European zoologists. His host at Batavia had, it appears, a very curious collection in the several departments of natural history. He made presents to his guest of several specimens, and among them was this beautiful pheasant, which was sent to England and described by Dr. Shaw.

(6249) *E. ignitus*, the Fire-Backed Pheasant of Java, the Macartney Cock, *Phasianus ignitus* Latham. Length of adult *male* about two feet. Skin of the nostrils stretching backwards over the sides of the head behind the eyes, and bluish-purple. A crest upon the crown of the head composed of naked-shafted feathers, expanding at their tips into slender spreading barbs. Head, neck, breast, belly, and upper part of the back, deep chalybean or steel-blueshot black; lower part of the back fiery orange-red or flame-colour, varying in intensity according to the incidence of the light, and passing like a zone round the body, though more obscure on the abdomen; rump and tail-coverts broad and truncated, brilliant bluish-green with a paler bar at the tip. Tail when erect folded in some degree like that of a hen; the middle feathers white, and the outside ones black with green reflections. Legs and feet vermilion, spurred.

Female.—Length about 20 inches. Plumage almost entirely rich cinnamon-brown; feathers of the upper parts slightly mottled with black; throat white; lower parts of a paler tint than those above, and having the feathers bordered with white. Elongated head-feathers capable of being erected into a crest, but not equal to that of the male. Tail folded. Legs spurless. It is a native of Sumatra. ('Atlas' to Staunton's 'Account of Lord Macartney's Embassy to China.')

(6250) *Gallus* (Brisson).—Bill moderate, strong, convex above, curved towards the point, cultrate at the base, and furnished with two pendent and compressed caruncles or wattles. Head surmounted with a fleshy crest or comb. Tarsi (in the male) furnished with a long and recurved spur; the hind toe only resting on the ground at its tip. Wings short and graduated. The 14 tail-feathers forming two vertical planes with the backs of the feathers towards each other, and so making what may be called a folded tail; the middle feathers longest and recurved. The ancestors from which our domestic poultry have descended were undoubtedly natives of Asia; but some doubt still hangs over the questions of the precise breed from which they came, and the exact locality where they were found. That fowls were domesticated at a very early period there is no doubt, and both historians and poets speak of the high antiquity of the race. Thus Peisthetærus relates why the cock is called Περσικὸς ὄρνις (the Persian Bird), and how it reigned over that country before Darius and Megabazus. (Aristoph., 'Birds,' 483 et seq.) To the forests and jungles of India we must look for the race in a state of nature; and though the denizens of the farm-yards may be the result of a mixture of many of the species which there inhabit, zoologists in general agree with M. Temminck in thinking that to the Malay Gigantic Cock or Fowl (*Gallus giganteus*, Temm.), and the Bankiva Cock (*G. Bankiva*, Temm.), we are chiefly, if not entirely indebted for our common poultry. The Domestic Cock and Hen are the Ἀλεκτρυών and Ἀλεκτορίς of the Greeks; Gallus and Gallina of the Romans; Gallo and Gallina of the Italians; Haus Hahn and Haus Henne of the Germans; and Coq (Gau, Geau, Gal, Gog), Gelline, and Poule, of the French. Bold, ardent, and vigilant the cock has been always considered the emblem of watchful courage, while the hen has been considered a pattern of maternal solicitude. In [illegible] and other polygamous [illegible] the object to be attained is the effective [illegible]nation of the greatest numbers of females by the most vigorous male. In the cock accordingly the spurs are developed as the sexual organs are matured; and it is principally with these weapons of combat that the battle which is to leave the field in the possession of the strongest is decided. The conqueror in his turn, as the weakness of age comes upon him, yields to a younger and more powerful rival; and thus a numerous, healthy, and stout progeny is secured.

(6251) *G. giganteus*, the Gigantic Cock, the

Kulm Cock of Europeans, often stands considerably more than two feet from the crown of the head to the ground. The comb extends backwards in a line with the eyes; it is thick, a little elevated, rounded upon the top, and has almost the appearance of having been cut off. The wattles of the under mandibles are comparatively small, and the throat is bare. Pale golden-reddish hackles ornament the head, neck, and upper part of the back, and some of these spring before the bare part of the throat. Middle of the back and lesser wing-coverts deep chestnut, the webs of the feathers disunited; pale reddish-yellow long drooping hackles cover the rump and base of the tail, which last is very ample and entirely of a glossy green, of which colour are the wing-coverts; the secondaries and quills are pale reddish-yellow on their outer webs. All the under parts deep glossy blackish green with high reflections: the deep chestnut of the base of the feathers appears occasionally, and gives a mottled and interrupted appearance to those parts. (Jardine principally.) Lieutenant-Colonel Sykes, in his Memoir on the Birds found in the Dukhun (Deccan), states that it is only there met with as a domestic bird, and that he has reason to believe that it is not a native of India, but has been introduced by the Mussulmans from Sumatra or Java. The iris, he says, of the real game bird should be whitish or straw-yellow. The Colonel landed two cocks and a hen in England in June, 1831; and they bore the winter well. The hen laid freely, and in September, 1832, had reared two broods of chickens. The cock had not the shrill clear pipe of the domestic bird, and his scale of notes appeared to be more limited. A cock in the Colonel's possession stood 26 inches to the crown of the head, but they attain a greater height. The length from the tip of the bill to the insertion of the tail, 23 inches. Hen one-third smaller than the male. ('Zool Proc.' 1832.)

(6252) *Gallus Bankiva*, the Bankiva Cock, is the Coq et Poule Bankiva of Temminck; Ayam Utan, or Brooga ('Linn. Trans.,' xiii.); Javan Cock of Latham; and many Bantams resemble it very closely. The space round the eyes and throat bare, comb, much [illegible]ped, deeply lobated along the upper [illegible]les of the lower mandible rather large, [illegible]lear, brilliant, golden-orange hackles cov[illegible]head, sides of the neck, back, and rump. Upper part of the back below the hackles bluish-black, the middle and lesser wing-coverts rich deep chesnut, with the webs of the feathers disunited; greater coverts steel-blue, secondaries the same, with a broad chesnut border; quills brownish-black, edged with pale reddish-yellow. Tail black, richly glossed with green and blue. Under parts black. Sir W. Jardine states that he has seen three or four specimens of another bird very closely allied to *G. Bankiva*, but rather larger, and certainly distinct: they were all from the continent of India.

(6253) *Gallus aheneus*, the Bronzed Cock, figured by M. Temminck from a specimen sent from the interior of Sumatra by M. Diard. This is somewhat larger than the Bankiva Cock, and its large comb is without dentilations; indeed the edge is quite unbroken; the feathers of the head, neck, and upper part of the back are rather elongated, but not hackles. The Fork-Tailed Cock (*G. furcatus*, Temm.; *G. Javanicus*, Horsf.) has the comb also entire, and the throat is adorned with a single large wattle springing from the centre. The head, neck, and upper part of the back are covered with feathers, which are not hackles, shorter and more rounded than those in the Bronzed Cock.

(6254) *Gallus Sonneratii*. This is the Coq Sauvage of Sonnerat; Coq et Poule de Sonnerat of Temminck; Sonnerat's Wild Cock of Latham; Rahn Kounrah of the Mahrattas; Jungle Cock and Jungle Fowl of the English sportsmen in India. The size of the male is nearly equal to that of a domestic cock; but the bird is altogether lighter, more graceful, and has a higher bred look about it; comb large, and with an unequal margin, but though this margin is jagged, it is not deeply dentilated; wattles double, depending from the base of the lower mandibles; hackles of the neck and of the wing and tail-coverts dark-grayish, with bright golden-orange shafts dilating in the centre and towards the tip into a flat horny plate. In some of these feathers the shaft takes an elliptical or oar-like shape; in others it puts on the appearance of a long inverted cone, from the centre of the base of which a battledore-like process arises. The substance and appearance of these plates have been not inaptly compared with the wax-like plates which ornament the wings and tail of the Bohemian Chatterer. The effect produced by this modification of the shafts is singular and beautiful. Feathers of the middle of the back, breast, belly, and thighs, deep rich gray, with paler shafts and edges; tail generally rich deep-green; the feathers which immediately succeed the hackles are rich purple, with a pale yellow edge; those next in succession are golden-green, with gray edges, and all are glossed with brilliant metallic reflections. Bill, legs, and feet, yellow. The living bird presents altogether a rich and striking object, especially when the sun shines on the plumage. Female less than the cock by about a third, without comb or wattles, but a trace of nakedness round the eye. The plumage (generally) is without the horny structure which distinguishes that of the male. Upper parts uniform brown; neck feathers with dark edges, those of the back and wing-coverts with a pale streak along the shaft, and those of the wings, tail-coverts, and tail, waved and mottled with darker pencillings; throat and front of the neck white; feathers of the rest

of the lower parts, greyish-white, edged with dark brown, which predominates towards the vent. Legs and feet bluish-grey. Colonel Sykes, in his valuable Catalogue, notes this noble bird as being very abundant in the woods of the western Ghauts, where (and this is well worthy the attention of ornithologists) he says there are either two species or two very strongly marked varieties. In the valleys, at 2000 feet above the sea, he tells us Sonnerat's species is found slender, standing high upon the legs, and with the yellow cartilaginous spots on the feathers, even in the female. In the belts of wood on the sides of the mountains, at 4000 feet above the sea, there is a short-legged variety. The male has a great deal of red in the plumage, which Sonnerat's has not: the female is of a reddish-brown colour, and is without cartilaginous spots at all: "in fact," continues the Colonel, "the female of this variety is the *G. Stanleyi* of Mr. Gray's 'Illustrations.'" Dr. Latham remarks that this Jungle Fowl is by far the boldest and strongest for its size, and that it is anxiously sought after by cockfighters in Hindustan, who rely on it for victory when pitted against larger game cocks.

(6255) *Tragopan*, Cuvier (*Ceriornis*, Swainson).—Head crested on the crown, partly naked (on the cheeks and round the eyes), the naked parts terminating in horn-like caruncles behindthe eyes; under the lower mandible and on the forepart of the throat a subpendent composite carunculated wattle. Tarsi armed with a blunt spur in the male; unarmed in the female. Mr. Gould ('Century of Birds from the Himalaya Mountains') remarks that the genus *Tragopan* appears to take an intermediate station between that of *Meleagris*, and the more typical *Phasianidæ*, forming one of the links of a chain connecting these groups of the Rasorial order. The affinity of this genus, he observes, to that of *Meleagris*, is evident in many characters; nor are some wanting which indicate a relationship to *Numida*, and even to *Francolinus*.

(6256) *T. Satyrus* appears to have been the only species originally known. Mr. Gould, in his 'Century,' describes another species, *T. Hastingsii*, and refers to another, which Dr. Gray, of the British Museum, has dedicated to M. Temminck. ('Indian Zoology.')

(6257) *T. Hastingsii*. Head of the adult male covered with a pendent crest of feathers, which, as well as the ear-coverts and throat, are black; the neck and shoulders are rich maroon; the chest, rich, glossy orange-red; the naked skin around the eyes is red; the fleshy horns and wattles mingled blue and purple; the upper parts exhibit a mixture of zigzag lines and marks of dark and light brown, with numerous and distinct spots of white; each of the upper tail-coverts ends in a large white eye, bordered on the sides with brown, and tipped with black; the tail deepens till it ends in uniform black; the feathers of the under surface are maroon, largely tipped with black, in the centre of which is a large white spot; the beak is black, the tarsi brown. In the young male the plumage is much less brilliant, the wattles being of a pale flesh-colour, and little developed, as is also the naked skin of the face. The plumage of the female consists of a uniform brown, mottled and barred with mingled lines and dots of various tints, the feathers of the back and chest having a central dash of a lighter colour; the head is crested, with short rounded feathers; the sides of the cheeks are clothed, and there are neither fleshy horns nor wattles. (Gould.) Mr. Gould observes, that although this species and *T. Satyrus* are closely allied to each other, and doubtless possess similar habits and manners, he is led to believe that their local distribution is somewhat different; at least, he generally receives but one species in a collection from the same quarter; *T. Satyrus* being transmitted from the Nepaulese Hills, while *T. Hastingsii* is sent from the more northern range of the Himalayas. He further well observes that the changes of plumage which birds of this genus, especially *T. Hastingsii*, undergo in passing from youth to maturity (and this is well illustrated in Mr. Gould's beautiful plates), are such as to have caused an apparently erroneous multiplication of species.

(6258) *T. Satyrus*, according to the same author, is an exclusive inhabitant of the colder regions of the mountains, in conjunction with the *Lophophorus*, its approximate relative, feeding on grains and roots, the larvæ of ants, and other insects.

(6259) PHASMIDÆ, a tribe of Orthopterous Insects, embracing a number of exotic forms which have been often included in the *Mantidæ*, from which they are distinguished by the fore-legs being of the ordinary size, and fitted like the rest for walking rather than running. From the other *Orthoptera* they are distinguished by the hind legs not being saltatorial. The body is generally long and slender. The head is of moderate size, of an oval subdepressed form, porrected, with large globular eyes, in front of which the antennæ are placed, which are variable in form, but ordinarily long, slender, and composed of a great number of articulations. The ocelli are rudimentary or obsolete. The labrum is deeply notched in front; the jaws are strong and horny. The dorsal surface in both sexes consists of nine segments, but only seven are distinct in the females. All the legs are alike, being long and slender, often armed with short spurs along the edges. The fore wings are of small size, and attached at the posterior part of the mesothorax. The true wings are very large and attached to the anterior part of the metathorax. As they far exceed the wing-covers in size, it is essential that provision should be made for their defence. This is effected not as in the earwig, by the

transverse folding of the wing as to enable it to be folded beneath the small wing-cover, but by the front margin of the hind wing being greatly thickened, serving as a flat plate, beneath which the other part of the wing is folded longitudinally, the latter part being often differently coloured. Thus in some species the short wing-covers and the front margin of the wing are pale-green, whilst the other part of the wing is pink. Many species however remain throughout their lives without ever acquiring wings or wing-covers." (Westwood, 'History of Insects.') The odd appearance of these insects have got for them the name of Walking-Sticks, Straws, Leaves, Spectres, &c., and certainly nothing can be imagined more curious than the forms they assume. In many instances they might be mistaken for a portion of the branch of the trees on which they rest.—*Eng. Cyc.*

(6260) PHILADELPHACEÆ, *Syringas*, a natural order of Exogenous Polypetalous Plants, with an inferior ovary, the principal genus being that after which the order is named. The species are American, European, and Asiatic shrubs of temperate climates, with opposite leaves, distinct styles, and capsular fruit, containing a large number of minute seeds.—*Eng. Cyc.*

(6261) PHILADELPHUS, a genus of plants the type of the natural order *Philadelphaceæ*, which is also the name of a tree, now unknown, mentioned by Athenæus, but was applied to the present genus by Bauhin. *Philadelphus* is characterised by having a calyx with an obovate-turbinate tube and a 4-5-partite limb. The greatest number of species are indigenous in North America, whence they have been introduced into the shrubberies of this country, to which they form a highly ornamental addition. A species has also been discovered in the Himalayas, at elevations of 6000 and 7000 feet, of which there are two varieties, sometimes considered distinct species, *P. tomentosus* being apparently only a more advanced state of *P. triflorus*. The best known species however is *P. coronarius*, commonly called Syringa, which is so easy of culture, and found in most gardens. It is supposed to be a native of the south of Europe, but it has hardly ever been found in a wild state, and even, in these few cases, it may have escaped from cultivation. As one species has been found in the Himalayas, there is no reason why other species should not exist still farther to the north-west, as in the Hindoo-Koosh, and that the Syringa may be found to be one of those plants which, was in early times introduced from some part of the Persian Region of botanists into the south of Europe.—*Eng. Cyc.*

(6262) PHILADELPHUS CORONARIUS. PHILADELPHEÆ. A handsome shrub, producing white blossoms, having the appearance and [illegible] of orange flowers; propagated by seed or [illegible].—*Riddell.*

(6263) PHILLYREA. Of this genus, Wight gives, *Panicularia alaterna*, 1242; and *terminalis affinis*, 736.

(6264) PHILLYREA PANICULATA. OLEINEÆ. A small tree with oblong ovate leaves; flowers in terminal panicles, pure white, bending down the branches, and giving the tree a graceful appearance. Introduced from China.—*Riddell.*

(6265) PHILOMELA, a genus of Birds belonging to the family *Sylviadæ*. *P. Luscinia* the Nightingale, is the most celebrated of the song-birds of the Old World. This well-known species is the Ἄηδων of the ancient Greeks; *Luscinia* of the Romans; Rossignuolo, Rusignuolo, and Usignuolo, of the Italians; Rossignol of the French; Ruisenor of the Spanish; Nachtigall of the Germans; Nachtegahl of the 'Fauna Suecica;' Nattergale of Brunnich; and Eos of the Welsh. It is the *Luscinia* of Gesner, Aldrovandus, Willughby, Ray, and Brehm; *Motacilla Luscinia* of Linnæus; *Sylvia Luscinia* of Latham and others; *Curruca Luscinia* of Fleming; and *Philomela Luscinia* of Selby, Gould, and Swainson. The following is a description of this bird:—Rich brown above; rump and tail with a reddish tinge; throat and middle part of belly dirty or grayish white: lateral parts of the neck, breast, and flanks, gray; bill and legs light brown. Sexes alike. The Nightingale shuns observation, abiding in the thickest coverts, and in these the nest is sometimes placed on a low fork, but generally on the ground. Withered leaves, particularly those of the oak, very loosely confined with dried bents and rushes, and lined internally with fine root-fibres, form the structure. The eggs, of an olive-brown, are four or five in number. After the young are hatched, generally in June, the melodious song of the male ceases, and is succeeded by a low croak, varied occasionally with a snapping noise; the first is considered to be meant for a warning, and the last as a defiance. The food consists, of insects, such as flies and spiders, moths and earwigs. Green caterpillars were the food brought by the parent birds to the nest of young nightingales taken by Colonel Montagu. It is not improbable that the bird's choice of localities is in some measure determined by the absence or presence of some favourite insect food. There is another European Nightingale (the Thrush Nightingale, *Philomela Turdoides* of Blyth, *Luscinia major* of Brisson, *Sylvia Philomela* of Bechstein) inhabiting central Europe. The song of this species is loud, but far inferior to that of the true Nightingale. It is said to be common in Egypt.—*Eng. Cyc.*

(6266) PHILYDRACEÆ, *Waterworts*, a natural order of Endogenous Plants, constituted by Brown to receive the genus *Philydrum* and *Helonias*. They are allied, according to Lindley, to *Commelinaceæ*, *Orchidaceæ* and *Irridaceæ*. The species are grassy-looking plants, with dis-

talous flowers, to calyx, three stamens, of which two are abortive, and an embryo in the axis of a fleshy albumen; they have erect stems, and ensiform leaves. They are found in Australia, Cochin China and China, (Lindley, *Vegetable Kingdom.*)—*Eng. Cyc.*

(6267) PHLOMIS INDICA. Linn.

Toombi keeray, Tam.	Toombi koora, Tel.
Toombikee baujee, Duk	Drona, Sans.
Choomra, Hind.	

This green possesses a considerable degree of acrimony which the Natives temper by an admixture of some agreeable acid. "I am inclined to think that it is not a wholesome vegetable. Rumphius tells us that the acrid juice of the plant, which is called Dawn beran in Malays, the Woriahs in Amboyna squeeze into their eyes to make them bold and intrepid in War. Vide Rumphius, From vi. p. 40.—*Ainslie's Mat. Med. page* 257.

(6268) PHLOMIS. Labiatæ. Phlomis Russelliana.—Jerusalem Sage.—These are perennial and shrubby plants, with coarse hairy leaves resembling the common sage; the flowers are purple, red, yellow, &c., growing readily from seed in any common soil.—*Riddell.*

(6269) PHLOX. Polemoniaceæ. Phlox Drummondii.—This is an elegant genus of plants, and from their lively colours have a pretty appearance when grown in patches, the colours are red, purple, lilac, white, &c., grow readily from seed in a light garden soil.—*Riddell*, Phlox Drummonda and variety Lepoldina are useful annuals, succeed well on the plains either in pots or the flower beds, should be sown thinly, and when one or two inches high, transplanted where intended to flower, require in pots a somewhat loamy soil well manured and drained. Native of Texas, ripens freely, which is to be preferred to that imported.—*Jaffrey.*

(6270) PHŒNICOPHAUS TRISTIS, "Maboka" of the natives, with a note like that of the English cuckoo, as heard late in the season.—*Hooker. Him. Jour. Vol.* I. *p.* 27.

(6271) PHŒNIX, a genus of Palms, which has been so named from one of its species, the Date-tree, having been called so by the Greeks: this name is thought by some to be derived from Phœnicia, because dates were procured from thence. The genus is common in India and in the north of Africa, and one of the species grows in Arabia, the lower parts of Persia and along the Euphrates to Syria. The genus is characterised by having flowers dioecious, sessile in a branched spadix, supported by a simple spathe; calyx 3-cleaved, 3-toothed; corolla 3-petalled; stamens 6 or 3; filaments very short, almost wanting; anthers linear; (female) calyx urceolate, 3-toothed; corolla 3-petalled, with the tinct from each other, of which one only ripens; stigmas hooked; drupe 1-seeded; seeds marked on one side with a longitudinal furrow; albumen reticulate; embryo in the back of the seed; palms with stems of a moderate height and ringed, or marked with the scars of the fallen leaves; fronds or leaves pinnate; pinnæ or leaflets linear, with the spadix bursting among the leaves, surrounded with an almost woody 2-edged sheath; flowers yellowish-white; fruit soft, edible, of a reddish-yellow colour.—*Eng. Cyc.* Phœnix Palms, of which the date tree is at once the most important and popular representative, is a genus indigenous to Africa and Asia and embraces several species, the products of which are brought into the markets of India. Its trunk, marked with the scars of fallen leaves, is, in some species, so short that it hardly appears above ground It is not decided whether the East Indian *P. sylvestris*, Roxb. be or not the *P. dactylifera* of Linnæus in a wild state.—*Seeman.*

P. dactylifera,—the Date-Palm is spread over the whole of Southern Europe, Northern Africa, and South-Eastern Asia, and its fruit is largely imported into India. It has many varieties but is a noble tree, from fifty to eighty feet high, and attaining the age of one hundred years.—*Seeman.*

(6272) PHŒNIX ACAULIS? Buch: the *Schaap* of the Lepchas is a small stemless palm which grows in Sikkim on the driest soil and in the deep valleys. The Lepchas eat the young seeds and use the feathery fronds as screens when hunting.—*Hooker Vol.* I. *p.* 143. Phœnix Acaulis, a dwarf palm growing east of Siligoree in the Terai; a sure sign of a hungry soil.—*Hooker Him. Jour. Vol.* I. *p.* 400.

(6273) PHŒNIX DACTYLIFERA. Date. Linn.

Payr-Eetchum pullum. Tam.	Khurma, Pers.
Paynd K'hujoor, Duk.	Kehjoor, Hind.
Carjoora pundoo, Tel.	Choorma, Malay.
Temr, Arab.	Carjoora, Sans.

P. dactylifera, the Indian Date Tree, is common all over India, from thirty to forty feet high, and is one of the trees from which the *Toddy* or *Palm-wine* is drawn, the toddy being either drunk when fresh, boiled into sugar, fermented into an intoxicating fluid, or fermented for distillation into Arrack. Mats and baskets are made of the leaves.—*Seeman.* The Date-Tree, or Date-Palm, is one of the best known, and probably the earliest known of the palms, and though belonging to a family which abounds and flourishes most in tropical regions, itself attains perfection only in comparatively high latitudes. It is no doubt the species to which the name *Palma* was originally applied, as we may infer from its being common in Syria, Arabia, the lower parts of Persia as well as Egypt and the North of Africa, where it has

cultivated in many places, not only as a curiosity, but on account of its leaves, which are sold twice in the year, in spring for Palm Sunday, and in September for the Jewish Passover; and also, from the name not being applicable to the other species known to the ancients, as it is considered that the bunches of dates were likened to the fingers of the hand, as appears from the present specific name *dactylifera*, from the Greek δάκτυλος, a finger. It is the Palm-Tree of Scripture, and was emblematic of Judæa, as we see in coins with the inscription of *Judæa capta*. It is found in oases in the desert, and round Palmyra, which is supposed to have been named from its presence. This appears indeed to be only a translation of the Oriental name, which is Tadmore, supposed to be a corruption of Tamar (from 'Taur,' a Date), a city built in the desert by Solomon. The date-Tree is therefore a subject of classical as well as of scriptural interest, besides its fruit forming a large portion of the food of a great part of the Arab race, and also a considerable article of commerce. The Date-Palm being dioecious, that is, the stamens and pistils, or the male and female parts being not only in different flowers, but even on different plants, the crops entirely fail, or the fruit is worthless and unfit for food if fertilisation is in any way prevented. To ensure this, the Arabs have long been in the habit of hanging the clusters of male flowers on the trees which bear only female ones, and therefore the Date-Tree is one of those which led to a knowledge of the sexes of plants. The extensive importance of the Date-Tree is, says Dr. Clarke, one of the most curious subjects to which a traveller can direct his attention. A considerable part of the inhabitants of Egypt, Arabia, and Persia subsist almost entirely on its fruit. They make a conserve of it with sugar, and even grind the hard stones in their hand-mills for their camels. In Barbary they form handsome beads for paternosters of these stones. From the leaves they make couches, baskets, bags, mats, brushes, and fly-traps; the trunk is split and used in small buildings, also for fences to gardens, and the stalks of the leaves for making cages for their poultry. The threads of the web-like integument at the bases of the leaves are twisted into ropes, which are employed in rigging small vessels. The sap is obtained by cutting off the head of the palm and scooping out a hollow in the top of the stem, where, in ascending, it lodges itself. Three or four quarts of sap may be obtained daily from a single palm, for ten days or a fortnight, after which the quantity lessens, until, at the end of six weeks or two months, the tree is exhausted, becomes dry, and is used for fuel. This liquor is sweetish when first collected, and may be drunk as a mild beverage, but fermentation soon takes place, and a spirit is produced, which is distilled and forms one of the kinds of aruk (arrack), or spirit of eastern countries. Such being the importance and multiplied uses of the Date-Tree, it is not surprising that in an arid and barren country it should form so prominent a subject of allusion and description in the works of Arab authors, and that it should be said to have 30 names in their language. Many of these are however applied to different parts of the plant, as well as to these at different ages.—*Eng. Cyc.* The true DATE TREE (*Phœnix dactylifera*), the Palm tree of Scripture, flourishes in comparatively high latitudes, and is well known to afford the principal article of food the natives of Arabia and of the North of Africa: while the leaves are employed in making mats, baskets, &c.; and at Cairo cordage is made of fibres obtained from the footstalks of the leaves. Though the tree grows well in India, it does not there produce any edible dates; but *Phœnix sylvestris*, the *Kujjoor*, of India, which closely resembles the former in character, is found in every part of that country, near Madras, in Mysore in Bengal and the North-West provinces up into the Punjab. This tree is especially valued in many places as its sap or Palm juice (*tari*) is either drank fresh from the tree, or fermented for distillation, when it yields a common kind of spirit or *aruk*. In Bengal it is valuable as yielding a considerable quantity of the sugar produced in that province, and known as Date sugar. Each tree, "on an average, yields 180 pints of juice, of which, every twelve pints are boiled down to one of *goor* or *jaguri*, and four of goor yield one of good powder sugar; so that the average produce of each tree is about seven or eight pounds of sugar annually." (Roxburgh.) The leaves are very generally employed for making mats and baskets and also bags in Bengal. The footstalks of the leaves are beaten and twisted into ropes, which are employed for drawing water from the wells in Bellary and other places. One species of *Phœnix* (*P. paludosa*), the *Hintal* of Bengal abounds in the Sooonderbunds while another *P. farinifera* common on dry, barren, sandy lands on the coast, and on the hilly country between the Ganges and Cape Comorin. Its stem abounds in farinaceous matter, which the natives make use of as food in times of scarcity. The leaflets are wrought into mats for sleeping on. The common footstalks of the leaves are split into three or four, and made into baskets of various kinds.—*Fib. Pl. p.* 96. In Tenasserim, Mr. Mason has seen young date trees raised from the seeds of the dried dates that are imported, and there is no apparent reason why the tree might not be cultivated. The dates that grow in India are of a very inferior quality to those brought from Persia and Arabia. The finest Arabian date we are told by Dr. Herbert, come from a town called Hagiar in the province of Bahrain.—*Mason. Ainslie. p.* 36.

(6274) PHŒNIX FARINIFERA. Is a

dwarf species. The fruit ripens in May, and a species of sago is procured from the trunk, which is split and dried, and then beat in wooden mortars until the farinaceous parts are detached.—*Jaffna*. It is a native of dry ground or sandy hills, not far from the sea on the Coromandel Coast. It flowers in January and February, and the fruit ripens in May. The leaflets are wrought into mats for sleeping on, and the common petioles are split into three or four, and are used for making baskets. The small trunk is generally about 15 or 18 inches long, and about 6 inches in diameter. It incloses in its substance a large quantity of farinaceous matter, which the natives use for food in times of scarcity. To procure this meal, the small trunk is split into six or eight pieces, and dried and beaten on wooden mortars till the farinaceous part is detached from the fibres; it is then sifted, to separate them; the meal is then fit for use. The only further preparation which this meal undergoes is the boiling it into a thick gruel, or conji. It seems to possess less nourishment than common sago, which is obtained in a similar manner from another palm, and is less palatable when boiled, but it has saved many lives in times of scarcity.—*Eng. Cyc.* Seeman tells us it is a dwarf plant, the trunk about one or two feet high, and so enveloped in the leaves as to appear like a bush. It is common on the peninsula of India, on dry barren sandy ground. Its leaflets are wrought into sleeping mats. The common petioles are split into three or four, and used to make baskets of various kinds. The exterior or woody part of the trunk consist of white fibres matted together, these envelope a large quantity of farinaceous substance which the natives use for food in times of scarcity. To procure this meal, the small trunk is split into six or eight pieces, dried, and beaten in wooden mortars, till the farinaceous part is detached from the fibres; and the meal, when separated by sifting, is fit for use, by being boiled into a thick gruel or conjee. It is, in fact, an inferior sago.—*Seeman.*

(6275) PHŒNIX PALUDOSA. Roxb. THE MARSHDATE PALM. This dwarf palm, grows plentifully on the Sunderbuns, South of Calcutta. *Hooker Him. Jour. Vol.* I. *p.* 1. On the low islands in the rivers, and on the shores which are inundated with the highest tides, the marshdate palm abounds, a small tree about twenty feet high, no thicker than a walking cane; whose fruit looks precisely like a bunch of dates, but it is not edible. Griffith says: "It is well worth cultivating on account of its elegance, and its being adapted for bank scenery."—*Mason.* P. paludosa, is the most Southern Indian species of the phœnix palms, and its elegant impenetrable tufts, well adapt it for bank scenery. The trunks of the smaller trees serve for walking sticks, the long trunks for rafters and the leaves for thatch.—*Seeman.*

(6276) PHŒNIX SYLVESTRIS. ECTCHA WOOD TREE.

Ectcha maram, TAM.

Phœnix sylvestris. Capt. Pharye informed Mr. Mason that he saw a wild date palm near one of the kyoungs in Amherst province, but though so abundant on the Hooghly this is the only one he ever heard of in the Provinces.—*Mason.* Phœnix Sylvestris is a species common in the arid parts of India, and there commonly called Khujjoor by the natives, and the Date-Tree by Europeans, which it resembles in appearance. In its parts of fructification it is like P. farinifera, but differs in growing to be a tree, with a tall pretty thick trunk and large yellowish or reddish fruit. It yields Tari, or palm wine, commonly called Toddy. The mode of obtaining this is by removing the lower leaves and their sheaths, and cutting a notch into the centre of the tree near the top, from which the liquor issues, and is conducted by a small channel, made by a bit of the palmyra-tree leaf, into a pot suspended to receive it. This juice is either drank fresh from the tree, or boiled down into sugar, or fermented for distillation when it gives out a large portion of spirit, called Aruk. Mats and baskets are made of the leaves. Sugar has always been made from this species, and accounts of it have been given by Drs. Roxburgh and Buchanan Hamilton. Date-sugar is not so much esteemed in India as that of the cane, and sells for about one-fourth less. It has sometimes been imported in considerable quantities into England, but is not distinguished from the cane sugar. Dr. Roxburgh calculated, 40 years ago, that about 100,000 lbs. were made annually in all Bengal. At the age of 7 or 10 years, when the trunk of the tree is about 4 feet high, it begins to yield juice, and continues productive for 20 or 25 years. The juice is extracted during the months of November, December, January, and February, during which period each tree is reckoned to yield from 120 to 240 pints of juice, averaging 180 pints. Every 12 pints, or pounds, is boiled down to one of goor, or jagari, and four of goor yield one of good sugar in powder, so that the average produce of each tree is about 7 or 8 lbs. of sugar annually.—*Eng. Cyc.* This tree grows all over East India, but it is said to do best on the sea coast. It produces 8 to 10 lbs. of sugar, and even 12 lbs. per tree.—*Bonynge, American, page* 143.

(6277) PHOLADIDÆ, a family of Conchiferous *Mollusca*, embracing the genera *Pholas*, *Pholadidea*, *Xylophaga*, and *Teredo*. The *Pholadidæ* perforate all substances that are softer than their own valves. The burrows of *Pholas* are vertical, quite symmetrical, and seldom in

distinct. The Ship-Worms (Teredines) also make symmetrical perforations, and, however tortuous and crowded, never invade each other, guided either by the sense of hearing or by the yielding of the wood. The burrow has frequently a calcareous lining, within which the shell remains free. *Teredina* cements its valves to this tube when full grown; the opening of the burrow, at first very minute, may become enlarged progressively by the friction of the syphous, which are furnished with a rough epithelium, but it usually widens with much more rapidity by the wasting of the surface. As the timber decomposes the shelly tubes of the *Teredo* project; and as the beach wears away the *Pholas* burrows deeper. (Woodward.) The number of living species of *Pholas* noted by Mr. Deshayes in his Tables is 15, and of these one, *P. candida*, is recorded as living and fossil. Woodward, in his Manual of the Mollusca, gives 23 recent species of *Pholas* and 25 fossil. Forbes and Hanley give the following as British species:—*P. dactylus*, *P. parva*, *P. crispata*, *P. candida*, *Xylophaga dorsalis*, *Pholadidea papyracea*.

(6278) PHOLAS. Animal more or less thick and elongated rarely shortened.

(6279) *Teredo* is the name given by Linnæus to a genus of Testaceous Molluscs, highly interesting on account of the ravages which one of the species commits upon submerged wood. Linnæus, in the twelfth edition of the 'Systema naturæ,' placed the genus among his *Vermes Testacea*, between *Serpula* and *Sabella*. Cuvier, in his last edition of the 'Regne Animal,' makes *Teredo* one of the genera of his Enfermes, the fifth family of his Acephalous Testaceans, arranging the genus between *Pholas* and *Fistulana*.—*Eng Cyc.*

(6280) PHOLIDOTA ARTICULATA. In the suburbs of Maulmain, a white flowered species of pholidota is not rare.—*Mason.*

(6281) PHOOL-EL-KA-TEL, an odoriferous oil made by placing sweet scented flowers, in three or five successive patches, over gingelly oil seed, and then expressing the oil. The best is made at Gingi, and is sold at 1½ rupee for two pounds.—*Herklots.*

(6282) PHOOT. Cucumis Momordica.—Field Cucumber. A wild species of cucumber sown generally in the fields amongst Jaworie, and is something between the melon and cucumber; it keeps for a long time if not too ripe and would be valuable as a store vegetable for sea.—*Riddell.*

(6283) PHORMIUM, a genus of Plants of the natural family of *Liliaceæ*, tribe *Agapanthæ* of Endlicher, *Asparagæ* of Lindley, contains only a single species, which is remarkable for its useful product, so well known under the name of New Zealand Flax, and which is found indigenous in New Zealand and Norfolk Island.—*Eng. Cyc.*

(6284) PHORMIUM TENAX has a coloured tubular perianth, of which the tube is very short, and divides into six segments, of which the three inner are the longest; stamens six, inserted into the base of the tube, ascending, exserted; capsule oblong, 3-cornered: seeds numerous, compressed; embryo in the centre of the seed, longer than half the albumen, with its radicle next the umbilicus. The root is tuberous, fleshy, and bitter tasted; the leaves are numerous, all radical, linear-lanceolate, five or six feet long, and from an inch and a half to two inches broad, 2-rowed, equitant at the base, leathery, and very tough. Its flowers are numerous, showy, yellow-coloured, arranged on a tall branched panicle. The leaves of this plant yield a very beautiful and a very strong fibre, which has been imported in considerable quantities under the name of New Zealand Flax. It was expected to be much more useful than it has proved to be, in consequence of its having the defect of breaking easily when made into a knot. Being a plant of high southern latitudes, it was supposed that it might easily be grown in different parts of Europe. The French have attempted to cultivate it near Cherbourg, Toulon, and other places, and it has been introduced into Ireland, the moist insular climate of which is probably favourable to its growth. It grew remarkably well for a number of years in the Chelsea Botanic Garden, but was killed by the severe winter of 1837-38. Its cultivaton has also been attempted in Australia, but has not yet succeeded to any extent.—*Eng. Cyc.*

New Zealand Flax (*Phormium tenax*)—was discovered by the celebrated Cook in New Zealand—as he says "the country produced a grass plant, like flags, of the nature of hemp or flax, but superior in quality to either; of this the natives make clothing, lines, nets, &c." It grows both on the north and the south coast. It was introduced in the year 1798 into the south of Ireland, and has been found to flourish on the west coast of Scotland, though European winters are occasionally too severe for it. The native name of the plant is *koradi* or *korere*, while the fibre is called *muka*. The leaves of the plant are perennial, hard, sword-shaped, from five to seven feet in length, with a flower-stalk rising four or five feet above them, and bearing a profusion of yellow flowers, followed by triangular seed-vessels, filled with flat and thin black shining seeds. According to Salisbury, three-year old plants yield on an average, thirty-six leaves, beside offsets from the roots. Six leaves produced one ounce weight of dry fibres, after being scutched and cleaned; and he calculated that an acre cropped with these plants, three feet apart (but they could not be placed so near without interfering with each other), will yield

more than sixteen cwt. "The leaves are cut when full-grown, macerated in water for a few days, and then passed under a weighted roller." The natives of New Zealand cut the leaves when full-grown, and separate the fibres while yet green. Mr. G. Bennett states that a lateral incision is made with a large shell on each side of the leaf, merely to cut through the epidermis, which is first removed, and then, what he calls the internal epidermis, probably a part of the cellular tissue, "which agglutinates the fibres, and, if not removed, deteriorates the flax." The principal operation is scraping with the shell, and then separating the fibres with the thumb-nails, and then employing combs for a more minute separation. The fibres are subsequently dried in the sun, and are perfectly white; some stout and strong, others fine and silky. It is said that "the plant may be shorn of its leaves in the morning, and before the sun has set be ready for weaving into cloth." The same thing may, no doubt, be done with others of these naturally white endogenous fibres. Considerable quantities were at one time imported, and a factory was established by Capt. Harris for their manufacture, but the supply seems to have been irregular, and now to have fallen off rather than increased. Mr. J. Wood, in the year 1844, in a communication to the Agricultural Society of India, called attention to the New Zealand Hemp, as a plant which was very hardy and would thrive in any soil or climate, but that it preferred swampy lands. He stated that it was often met with in New Zealand, thriving three or four feet under sea-water, (but it is also found at some distance from the seashore). He therefore thought the locality of the Soonderbunds, extending from near Calcutta to the sea, to be well adapted for this plant: and which would be profitable in a country where labour was so cheap. But it seems to have been forgotten, in this, as well as in a paper in the first volume of the 'Transactions of the Society,' that a plant which flourishes so far south as New Zealand, and succeeds well both in Scotland and in Ireland, is not likely to do well in so tropical a situation as that of the Soonderbunds. An interesting set of specimens of New Zealand Flax, showing the native method of preparing the fibre and of dyeing it black, were sent to the Exhibition of 1851, by Taohui, a New Zealand chief; and another, a very valuable and suggestive set of specimens of the fibre and its tow, by Mr. E. W. Trent (v. 'Illust. Col.,' xli, p. 187), which he described as having been separated entirely by machinery invented by himself. If this fibre can be so prepared, then it is evident that others of the same nature may be successfully treated in a similar manner. These fibres are applicable to a variety of purposes, either of a textile nature or for cordage, and will, like the other white fibres we have mentioned, take colour. The strength of the fibres is considerable, for in some experiments by De Candolle, in which, however, that of Agave is understated, there is no doubt that the New Zealand Flax, which bore 28·7, was stronger than either Flax or Hemp, which bore respectively 11¾ and 16¾. It has also the advantage of being lighter, but has the disadvantage of many of the white fibres of breaking at a knot. Mr. J. Murray, in his pamphlet on this plant, printed on paper made from its leaves, states that the ship Atalanta, which plied between Southampton and the Channel Islands, was completely equipped with cordage and rigging made of *Phormium tenax*. He further continues—"I have seen specimens of ropes, twine, yarn, lines, sailcloth, sacking, bedtick, &c., made of *Phormium tenax*, also fine fabrics of various kinds, affording demonstrable evidence that its fibre is susceptible of being woven into tissues of the most delicate description, or manufactured into materials of the strongest and coarsest kind. The sails, cables, and running rigging of the beautiful model of the frigate presented by his late Majesty William the Fourth to the King of Prussia, were entirely formed of *Phormium tenax*. Capt. Harris's yacht, a perfect gem in naval architecture, was supplied with a mainsail composed of three different varieties of New Zealand flax, and the cordage made of *Musa textilis*," that is, of Manilla hemp, of which we have before treated.—*Royle. Fib. Pl.*

(6285) PHOTINIA GLABRA, is common in China and ornamental. It is a noble evergreen, which in the winter becomes covered with bunches of red berries.—*A Res. among the Chi, p.* 51.

(6286) PHOTINIA SERRATIFOLIA.

Doukyat, Burm.

Found in the neighbourhood of Rangoon and along the banks of the streams in the Rangoon districts, in the direction of the Teak forests. Red wood, adapted to cabinet making.—*McClelland.* The leaves of this plant are used for a green dye.—*McClelland.*

(6287) PHRAGMITES, a genus of Plants belonging to the natural order *Gramineæ*. *P. communis*, the Reed, is a plant formerly regarded as a species of *Arundo*, but now separated from that genus on account of its lower floret being male while the others are hermaphrodite, and its rachis being fringed with long silky hairs. It is a tall plant with annual stems and a perennial root and is found exclusively in places overflowed even during summer. In such situations it is found abundantly in Great Britain, and occurs all through Europe, is common in Siberia, Japan, North America, and even Australia, forming thick coverts, and yielding an abundance of stout durable grass of great value for the pur-

need of thatching the roofs of buildings. This is undoubtedly the φραγμίτης of the Greeks. A second species is said to grow in Egypt, and a third in the island of Mauritius; the two latter species are however little known.—*Eng. Cyc.*

(6288) PHRYNIUM DICHOTOMUM.

Theen, BURM.

Very plentiful in the forests of the Pegu and Tounghoo districts. It is said to afford a strong fibre.—*McClelland.*

(6289) PHYLLANTHUS. Of this genus of plants Dr. Wight gives bacciformis, 1893; leprocarpus, 1895; Madraspatensis, 1895; multiflorus, 1901; myrtifolius, 1902; Niruri, 1894; polyphyllus, 1895; rhamnoides, 1895-98-1900; Rheedii, 1895; scandens, 1895-99; tetrandrus, 1900-1902-1903; turbinatus, 1897; vitis idœa, 1293-1900.

(6290) PHYLLANTHUS. There is a small tree very abundant at Maulmain, and in many other localities on the Tenasserim Coast, belonging to the genus phyllanthus which bears a small intensely sour fruit, that is valued by the natives.—*Mason.*

(6291) PHYLLANTHUS EMBLICA, Linn. EMBLIC MYROBALAN.

Oosarica, TEL.	Topoo nellee, TAM.
Aola, Anola, HIND.	Awla or Aunlee, DUK.

This grows to a pretty large tree and is cultivated throughout most parts of India, and is found wild throughout the Concan and Deccan. —*Riddell.* The tree is cultivated at Ajmeer, but grows wild in Kotah and Mewar.—*Genl. Med. Top. p.* 208.

The Flower.

Nelliepoo, TAM.	Woosheri ke poo, TEL.
Aonli ka pool, DUK.	Amalaka. SANS.
Vurdi Amludge, ARAB.	

This flower is supposed to be cooling and gently aperient, and is prescribed in conjunction with other articles in the form of electuary.—*Ains. Mat. Med. p.* 94.

The Fruit.

Nellie pullum, TAM.	Amuleh, PERS.
Aoula ka pull, DUK.	Aunwera, HIND.
Amluj, ARAB.	Woosherikaia, TEL.

Anola, Aola, Phyllanthus Emblica. Emblic Myrobalan. The fruit is brought from Kotah and Mewar. It is used abundantly fresh or dried as a condiment, being pickled also; and in dyeing, and to weigh the hair with; the fruit is very acid and astringent, and contains gallic acid. The use of this fruit was supposed beneficial as an adjuvant in treating the scurvy at Nusseerabad.—*Gen. Med. Top. p.* 124 & 208. The fruit resembles the gooseberry, having a sharp acid juice, and is eaten raw by the natives, and is sometimes made into preserves; the bark is strongly astringent and is used for tanning leather.—*Riddell.*

(6292) PHYLLANTHUS LONGIFOLIUS.

Cheera nella, HIND.	Hurpororí, DUK.

A small tree, commonly cultivated for the sake of its fruit, which is the size of a large gooseberry; it is more esteemed by the Europeans than the Emblica, and is used both as a pickle and preserve—*Riddell.* In Ajmeer, in gardens, but wild in Kotah, the acid berry is eaten.—*Med. Top. p.* 208.

(6293) PHYLLANTHUS MULTIFLORUS, PHYLLANTHUS, MANY FLOWERED, BARK OF. Willd.

Poola Puttay, TAM.

This bark, which is also called Neerpoola Puttay, from the plant growing near water, is occasionally employed by the Natives of India in the process of dyeing reddish brown.—*Ains. Mat. Med. p.* 191.

(6294) PHYLLANTHUS NIRURI, Native of the East Indies.

Sadee hazar munee, HIND. and BENG.	Nella userekee, TEL.

A common weed, according to many writers; the root is bitter and astringent, and a powerful diuretic. *P. urinaria*, (hazar munee. yerra userekee,) East Indies and Bourbon, is of similar properties, and used in several maladies; flowers sessile, capsules dull, scabrous, young plants deeply dark red.—*O'Shaughnessy, page* 551.

(6295) PHYLLANTHUS SIMPLEX, RETZ. Roxb. iii. p. 654.

Oochie userekee, TEL.

Fresh leaves, flowers, and fruit, with cummin seeds and sugar are made into an electuary, and given by the natives as a remedy for gonorrhœa; fresh leaves bruised with buttermilk are used to cure the itch. *Roxb.*—*O'Shaughnessy, page* 552.

(6296) PHYLLANTHUS VIROSUS. Up among the Circar mountains, where this chiefly grows, it is frequently a middle sized tree. In the forests of the low countries it is much smaller or only a large shrub. It flowers during the hot and beginning the wet season. The bark is a strong astringent and possesses the power of intoxicating fish, when thrown into the water where they are, which, like the berries of Menospermum cocculus, renders them easily taken.—*Roxb.* from *Rohde M. S. S.*

(6297) PHYLLANTHUS VITIS IDŒA.

Khaton Nirouri, RHEED.	Yerrapooroogoodoo, TEL.
Hunkata jooli, BENG.	

This is one of the most common of the family. It is found wild in every part of India, and seems to thrive well in all soils and situations, but amongst the mountains, it grows to be a tree; where as in the low lands, it is generally a large

shrub. It flowers and produces fruit all the year round. The wood is white hard and durable. The hill people employ it for various economical uses. Cattle eat the leaves. In drying for the hortus siccus they always become very black; it is frequently employed for ornamental hedges in gardens for which end it is well chosen, as its thick evergreen foliage and constant succession of beautiful red berries gives it a pretty appearance. *Roxb.—Rohde M.S.S.*

(6298) PHYLLODOCE, a genus of Plants belonging to the natural order *Ericaceæ*. It has a 5-parted calyx, an ovate corolla with a contracted 5-toothed mouth, 10 stamens inclosed, slender glabrous filaments longer than the anthers, short truncate cells opening by pores at the apex. The seeds are compressed and shining. The species are small evergreen shrubs, natives of the North of Europe, Asia, and North America.—*Eng. Cyc.*

(6299) PHYLLOPODA, (Latreille), a section of Entomostracous *Crustacea*, [ENTOMOSTRACA]. —*Eng. Cyc.*

(6300) PHYLLOSOMA, a family of *Crustacea*, called by Milne-Edwards Double-Cuirassed (Bicuirasses). It is composed of forms which are very remarkable for their rounded shape and the transparency of their teguments. The species are found in the seas of warm countries. M. Milne-Edwards remarks, that were it not for the beautiful blue of their eyes, they would not be perceived as they float on the surface of the water, so transparent are their bodies The seas of Africa and India, Australia and New Guinea furnish the greatest number of species. M. Milne Edwards divides the genus into three natural groups.—*Eng. Cyc.*

(6301) *Phyllosoma commune*, has the cephalic plate less than the thoracic plate, covering the base of the second pair of feet (or external jaw-feet); elongated, and narrowed forwards. It inhabits the seas of Africa and India.—*Eng. Cyc.*

(6302) *Phyllosoma claviconne*, from the seas of Africa and Asia, is another example of this section.—*Eng. Cyc.*

(6303) *Amphion Rehnaudii*, the only species known, was taken at Sea in the Indian ocean, by *M. Reynaud*, naval surgeon. Its length is about an inch; and its teguments, with the exception of those of the abdomen, are diaphanous. —*Eng. Cyc.*

(6304) PHYSALIS (from φῦσα, a bladder, in reference to the inflated calyx), a genus of Plants, belonging to the natural order *Solanaceæ*. It has a 5-toothed calyx; a campanulate rotate 5-lobed corolla; converging anthers opening longitudinally; a capitate stigma; smooth 2-celled berry, covered with the angular membranous inflated calyx. The species are annual or perennial herbs, rarely shrubs.—*Eng. Cyc.*

(6305) PHYSALIS ALKEKENGI, the Winter Cherry, is an herbaceous downy plant, with a perennial creeping root, ovate deltoid leaves; spotless flowers, ovate coloured calyx, and subulate segments. It is a native of Europe on exposed hills, and of Japan. The corolla is a dirty white; the calyx reddish-yellow, inclosing a red berry. The fruit of this plant was well known to the ancients, and is described by Dioscorides. In England however the fruit is seldom eaten, and the plant is cultivated chiefly on account of its appearance. In Arabia and Armenia, Spain, and Germany however the berries frequently supply the place of other eatable fruits. They have a subacrid and not unpleasant flavour, but the persistent calyx with which they are invested is very bitter. Ray speaks of these berries as a preventive of gout, and others have extolled them as diuretics, and recommended them in the treatment of dropsy.—*Eng. Cyc.* The Physalis Alkekengi, having some repute as a febrifuge, M.M. Dessaignes and Chautard analysed it, and succeeded in procuring a bitter substance, which they have called Physaline, forming a light white powder with a very slight shade of yellow, leaving in the mouth after a time a very marked taste of bitterness. This substance does not seem to have been used medicinally, nor has its value, if any, been ascertained. Were it otherwise it might be well to examine Physalis flexuosa of this country, used in native medicine as stimulent and diaphoretic.—*Ind. Ann. Med. Sci. for Apl.* 1856. *p.* 384. Honigberger, *p.* 324, tells us that its fruit (Halicacabum), the winter cherry, is what the Easterns call Kagnuj. The English have given the name of Kagnuj to the Physalis flexuosa or somnifera, as this is the name of the plant in the lower parts of Hindostan, in Bengal? The winter-cherry is used by the Hakims as a diuretic, and in ulceration of the urinary bladder. It is said to be purgative and is much used in veterinary medicine. The winter-cherry has long been abandoned in European practice and is now regarded as useless.—*Honigberger.*

(6306) PHYSALIS ANGULATA. COUNTRY GOOSEBERRY, OR WINTER CHERRY. Linn.

Takalie pullum, TAM.	Kaknuj, PERS.
Poplah, DUK.	Takkali pundoo, TEL.
Jouzul huruj, ARAB.	Agnimunda, SANS.

This has got the name of country Gooseberry in India, from its resemblance in taste to that fruit: it is the produce of a small bush which has been called by Botanists, "The tooth leaved Winter Cherry," and is of the class Pentandria and order Monogynia.—*Ainslie, p.* 233.

(6307) PHYSALIS FLEXUOSA, as also Physalis somnifera, grows among the ruins of the old city of Lahore. The Punjabees call the plant *agsend* not as stated by so many authors as also in the Bengal Dispensatory, *Asgend*. Asgend

(Ygrund) *Nagowri*, is a root officinal with the native doctors in the Punjab, and is imported from Hindostan. The seeds used by Honigberger under the name Physalis flexuosa semina, were not the seeds of the Lahore plant, but had been imported from Mooltan. They are kept by the druggists, who call them *Penir ke. big*. Piddington states that *Peneru* is Physalis flexuosa. Penir is the Persian name of chee-e, and as these seeds are employed in the coagulation of milk for making cheese, the derivation of its name is palpable. The plant which yields these seeds grows on the west side of the Indus river. The leaves which are very bitter, are used as an infusion by the Loanis in fever. Galium verum, Linn, was formerly used in Europe for the coagulation of milk. Its flowers are yellow, those of Peniru not known. The fruit of Physalis flexuosa is accounted diuretic, and the root and leaves powerfully narcotic, the latter are used in India as a poultice to inflamed tumors.—*Honigberger*, *p.* 324.

Common at Ajmeer the roots are sold by punsaris, and are considered stimulating and diaphoretic.—*Gen. Med. Top. p.* 183.

(6308) PHYSALIS PERUVIANA.

Tapureea, Hind.

The Winter Cherry. This plant, commonly called Cape Goosberry or Brazil Cherry, grows luxuriantly in a good soil. The seed should be sown at the commencement of the rains. The young plants when about six inches high should be set out in rows at least two feet apart from each other, sufficiently wide apart, in fact, to allow the gardener to pass easily between them. They may be grown either on sticks or on trellis, and should be carefully pruned. The young shoots bear the finest fruit, and if carefully attended to, will bear almost all the year round,—the excellence and abundance of the fruit well repaying for any extra care bestowed on the cultivation of the plant. Being of easy culture, it is hardly known to what a state of improvement this apparently worthless fruit may be brought. Produced under an improved method of cultivation, it is a most wholesome and useful fruit; none more so for tarts, or even for dessert, and for making jam or preserve. After seeing the common fruit, grown without care or attention, one would scarcely credit the size of that produced under proper and careful management. The bush should every now and then be carefully pruned, cutting out the old wood, as the new shoots provide the finest flavored fruit.—*Riddell.*

(6309) PHYSALIS PUBESCENS, Downy Winter Cherry, is a native of North America and the East Indies. The whole plant is densely clothed with down. The corolla is yellow marked with five roundish brownish-violet spots at the throat. The berries are yellowish when ripe; they are called Gooseberries, and are used as a substitute for them in many parts, and when preserved with sugar make an excellent sweetmeat. It is the Camaca of Brazil.—*Eng. Cyc.* Cultivated in Ajmere gardens for the fruit.—*Gen. Med. Top. p.* 183. "Brazil gooseberry," is occasionally seen in Tenasserim gardens.—*Mason.*

(6310) PHYSALIS SOMNIFERA. *Syn.* P. FLEXUOSA. Roxb. Fl. Ind. i.

Usgund, also Kakunj, Hind. | Amookanam (root): also Amkootang kaling, Tam.

A native of rocky places on the sea coast of the south of Europe and the East.—*O'Shaughnessy*. *Physalis somnifera*, has several shrubby branched stems, round and downy. The leaves are in lateral pairs, short-stalked, ovate, downy, and from two to four inches long. The flowers are axillary, subsessile, small, crowded, and of a greenish-yellow or white. The berry is red and smooth, and about the size of a pea. This plant is the Στρύχνος ὑπνωτικὸς of Theophrastus ('Hist. Plant.,' 9, 12); and the Στρύχνον αλικάκαβον of Dioscorides (4, 72). It is a native of rocky places in the south of Europe and the East Indies. It is reputed to be narcotic, diuretic, and alexipharmic. The leaves steeped in oil are in India applied to inflammatory tumours, and they are used in a similar way in Egypt. Kunth recognised this plant in Egyptian mummies.—*Eng. Cyc.*

(6311) PHYSOLOBIUM. Leguminosæ.—These plants are not much known. They are natives of the Swan River, and take their name from Physa, a bladder, and lobos, a pod, alluding to the shape of the seed vessels—*Riddell.*

(6312) PHYTELEPHAS (from φυτόν, a plant, and ἐλέφας, ivory), a genus of Plants belonging to the natural order *Pandaneæ*, of Brown, and originally referred by Lindley to the order *Cyclanthaceæ*, but in his 'Vegetable Kingdom' he places it with the Palms. Under this name it was first described by Ruiz and Pavon, in their 'Systema Vegetabilium Floræ Peruvianæ.' It was also described by Willdenow under the name *Elephantusia*, but the former name is now generally used. The substance called Vegetable Ivory consists of the seeds of species of *Phytelephas*. This genus is characterised by possessing pinnated fronds and an erect stem. The flowers are arranged on a spadix inclosed in a universal spathe, and are of two sorts, the one containing both stamens and pistils; the others only pistils. The spadix is crowded with flowers, and the stamens are very various; the style is divided into 5 or 6 deep segments; there is no visible calyx or corolla; the fruit consists of quadrilocular drupes, which are aggregated into a large muricated coriaceous head. The seeds are about the

size of a pigeon's egg, and of an oblong-ovate triangular shape. When young, they contain a crystalline liquor without odour or taste, which is regarded as a refreshing drink by travellers. In the process of growth however this once opaline liquid becomes milky and opaque, acquiring some taste and odour, and at last it is converted into a substance in many instances whiter and harder than ivory. If the liquid of the seed is kept long, even when it is clear, it becomes sour, thus indicating that although clear and tasteless it contains some carbonaceous principle, as well as water. There are two species of *Phytelephas*, yielding seeds of the same kind: the *P. Macrocarpa* has a low stem and large fruit, whilst the *P. microcarpa* has little or no stem and small fruit. These plants, which have an external character something between a palm and a cycas, occur in South America, in the valleys of the Peruvian Andes, and especially on the borders of the river Magdalena. The natives of these districts have used the seeds from time immemorial, for the purposes of making buttons, heads to walking-sticks, and various trinkets; but it is only within a recent period that they have been used for such purposes in Europe. They are now extensively so, as far as their size will permit them, for the manufacture of almost all the articles for which ivory had been in use before; and, as they can be made at a cheaper rate, their sale is at present somewhat extensive. In the use of the nuts for turning, considerable difference is found in their quality; some are comparatively oily and soft, and work up with ease, whilst others are so brittle as to be unmanageable in the lathe. They do not answer so well as ivory for the construction of delicate articles, as they are much more easily fractured; and although at first these seeds are whiter than ivory, they are not found to retain their colour so well. It might at first appear difficult to account for the germination of these plants, as the albumen, which is destined to nourish the young plant, is as hard as ivory; but this is provided against by the hard albumen absorbing water, and thus not only becoming soft and capable of being used by the embryo, but it also loses its whiteness. It regains these properties when dry. The embryo is small compared with the size of the seed, of a sweet taste, and lies inclosed in a little bag at one end of the seed, the presence of which is indicated by a slight swelling on the external part of the seed. When the seeds are brought into England they are contained in a soft external tegument of a light colour, and about the eighth of an inch in thickness, with a dark mark indicating the point of attachment. This covering is easily removed, and the seed underneath is of a dark brown colour, from a membrane which is closely attached to the albumen. In some cases this is of a reddish colour, especially on the smaller seeds, and these are probably the produce of the smaller species of the plants. When the seed is cut completely through, an irregular cavity is found in the centre. This should be attended to in working it. (Ruiz and Pavon, *Systema Vegetabilium Floræ Peruvianæ*; Cooper, Paper *On Vegetable Ivory*, in *Microscopical Journal*, No. 16.)—*Eng. Cyc.*

(6313) PHYTOLACCA, a genus of Plants the type of the natural order *Phytolaccaceæ*.—*Eng. Cyc.*

(6314) PHYTOLACCA ACINOSA. Roxburgh describes a *Phytolacca acinosa* obtained from Nipal, where the leaves are eaten after boiling, as is the case with the American species described below. It flowers in the Botanic Garden of Calcutta about the end of the cold season, and certainly demands careful trial.—*O'Shaughnessy, page* 527.

(6315) PHYTOLACCA DECANDRA. Poke weed, North America. Bigelow states that in emetic properties the root is very nearly equal to Ipecacuana, its use is however sometimes attended with slight narcotic symptoms. It is also used as an external application in itch, and tinea capitis.—*O'Shaughnessy, page* 527.

(6316) PHYTOLACCA ICOSANDRA. An herbaceous plant; leaves alternate, entire, without stipules; flowers racemose. A tincture from the ripe berries has the reputation of being a remedy for chronic rheumatism and syphilitic pain.—*Riddell.*

(6317) PIACABA, ATTALEA FUNIFERA. A most valuable palm, found in the native forests of the maritime provinces of Brazil, the fibres of its leaf stalks and other parts furnishes the best Cordage of South America.—*Seeman.* A coarse black fibre is obtained from the dilated base of the petioles. It is collected by the natives, and partly used for home consumption, partly exported to Europe, tied up in bundles of several feet in length, and sold in London under this name at about £ 14 the ton. It is manufactured into cordage in its native countries, and as it is light, cables made of it do not sink in the water. —*Seeman.*

(6318) PICIDÆ, a family of Scansorial Birds. The order *Picae* of Linnæus is thus characterised:—Bill (cuneus sarriens) cultrated, with a convex back. Feet walking, short, rather strong. Body 'tenaciusculum,' impure. Food 'quis, quiliæ.' Nest in trees; the male feeding the incubating female. Monogamy. Order analogous to the *Primates*.

The following is Mr. Swainson's systematic arrangement:—

Picidæ.—Bill straight, more or less conic. Toes placed in pairs.

Sub-family :—*Piciaæ* (*Picina*?), the True Woodpeckers. Bill wedge-shaped. Tongue vermiform.

(6319) *Picus*, Typical-Woodpeckers.—Bill perfectly wedge-shaped, cylindrical; the culmen straight; lateral ridges removed from the culmen. Versatile (outer posterior) toe always longer than the anterior (outer fore toe).

Sub-genera :—*Picus* (America and India); *Hemicircus* (India); *Dendrobates* (Africa, except two species from Tropical America); *Apternus* (Arctic Regions); and *Dendrocopus* (Universal.)

(6320) *Chrysoptilus*, Green-Woodpeckers.—Versatile and anterior toes of equal length. Lateral ridge nearest to the culmen, which is sharp, and either quite straight or very slightly bent. Bill depressed or widened at the base. Colour green banded or spotted with black. Sub-typical genus.

Sub-genera :—*Dendromus* (Africa and India); *Chloronerpes* (Tropical America); *Dryotomus* (America and Europe); *Chrysoptilus* (Tropical America).

(6321) *Malacolophus*, Rasorial-Woodpeckers.—Versatile toe shorter than the anterior, culmen curved. The lateral ridge (except in the typical group) wanting. Tarsus shorter than the versatile toe. Hind head with a crest of very soft feathers.

Sub-genera :—*Brachylophus* (Old World only); *Hemilophus* (India only). Typical :—*Malacolophus* (Tropical America only); *Meiglyptes* (India); *Chrysonotus* (India only).

(6322) *Colaptes*.—Tarsus lengthened and equal to the versatile toe; which latter is shorter than the anterior. Bill broader at its base than it is high; the sides compressed; the culmen considerably curved from its base; the lateral ridge either obsolete or entirely wanting. Nostrils partially defended by feathers.

Sub-genera :—*Geocolaptes* (Africa only); *Colaptes*.

(6323) *Melanerpes*.—Bill straight, more or less cylindrical; base wide; the ridge of the culmen slightly bent, but not very prominent; the sides rounded; the lateral ridge slight, and placed near but not close to the culmen. Gonys very long, as in the typical group. Nostrils nearly concealed. Wings long; the first quill spurious or very small; the second nearly as long as the third. Toes various. Habits gregarious and migratory. Colours black, varied with white and red. The fissirostral type (America only).

Sub-genera :—*Centurus*, *Leuconerpes*, *Melanerpes*, *Tripsurus*. Sub-family : *Buccoinae*, Barbets [BARBETS]. Bill surrounded with long bristles. Tail short, soft.

(6324) PICUS SHORII. Upper part of the head and elongated crest of the head and rump rich scarlet; a white line, extending from the base of the upper mandible to the occiput, edges the scarlet of the head; a black band originates behind the eye below this white line, passes through the ear-coverts to the back of the neck, and there spreads as far as to the back; cheeks and sides of the neck white, separated from the throat and forehead by a wavy black line passing from the gape to the sides of the chest; base of the lower mandible bordered by a brownish mark; throat white; back orange passing into various tints of scarlet on the shoulders and wing coverts, and on the rump into bright scarlet; quills, tail, and upper tail-coverts black; under surface dirty brownish-white, with black scale-like marks; bill and tarsi black. Length 12 inches. It is also found in the Himalaya Mountains. This three-toed woodpecker exhibits a close affinity with *P. tiga* (Horsf.) an inhabitant of the Indian Archipelago, as well in colouring as in the absence of the hinder toe, which in both birds is represented only by a rudimentary tubercle. Few, if any, of the tribe surpass it in brilliancy of plumage.—*Eng. Cyc.*

(6325) PICUS SQUAMATUS. Top of the head and occiput scarlet; above and below the eye a yellowish-white streak; a black line extending from the base of the lower mandible along the sides of the neck; the upper surface of a bright green; quill-feathers and tail dull olive-black, barred with white; throat and breast grayish-green; abdomen and under surface of a still lighter tint, marked with black scales closely and regularly disposed; bill yellowish-white, hornbrown at the base; tarsi brown. Length 12¼ inches. It is found in Asia, in the Himalaya Mountains.—*Eng. Cyc.*

(6326) PICUS CANUS, of the continent may be considered as a type of an intermediate class, and which are the only species found in Europe—the present species, as well as P. occipitalis, also a Himalayan bird, may be classed; all these birds being found, like the typical Woodpeckers, to frequent trees as a resort for food, while at the same time they equally subsist, like the ground-feeding species, on ants and other insects which they obtain on the surface of the ground. Mr. Gould further states that the locality of *P. squamatus*, as well as *P. occipitalis*, is believed to be confined solely to the higher parts of the mountains.

(6327) PICKLES AND THEIR ADULTERATIONS. To persons unacquainted with the subject, the title of this article, "Pickles and their adulterations," may appear somewhat singular, and they may be disposed to ask, Are not the girkins, cabbages, beans, &c., which we see in the bottles, what they appear to be? And are other vegetables than those commonly known to us mixed with the ordinary kinds? To these question we thus reply. "Girkins," on close examination, often turn out to be

but shrivelled or sliced cucumbers; the "young tender beans" to be old and tough; the "cauliflowers" to have run to seed, and the "red cabbage" to be nothing more than white cabbage turned into red by colouring matter, as a dyer would change the colour of a dress; further, that amongst the vegetables, not unfrequently employed for the purpose of pickle-making, are some which do not enter into the calculation of the epicure, as vegetable marrows,—which, when cut into pieces, form a very respectable imitation of cucumbers,—and sliced turnips, the identification of which would be apt to puzzle even a botanist, as well as certainly all those who are uninitiated in the secrets of a pickle-manufactory.

1st. That the vinegar used for pickling is of a very weak description, the percentages of acetic acid ranging between 1·48 and 2·91. It will be remembered, that, vinegar of good quality ought to contain from four to five per cent. of pure acetic acid.

2nd. That nineteen out of twenty of the vinegars submitted to analysis, poor as they were, yet owed a portion of their acidity to sulphuric acid, the amount of which varied, in the different samples, from. 38 to 2·52 in the 1000 grains; the largest quantity of this acid being detected in the vinegars in which the red cabbages were pickled.

3rd. That in the whole of the sixteen different pickles analysed for copper, that poisonous metal was discovered in various amounts: two of the samples contained a small quantity; eight rather much, one, a considerable quantity: three a very considerable quantity; in one, copper was present in highly deleterious amount; and in two, in poisonous amounts.

4th. It will be observed, that the pickles which contain the largest quantity of copper, are those which consist entirely of green vegetables, as girkins and beans.—*Food and its Adulterations, p.* 383.

(6328) PICRORRHIZA.

Teeta, Beng. | Nepalese Hoon ling, Thib.

This name is given in Bengal to the roots of bitter herbs. This name is given in East Nepaul in the Yaloong valley, to this plant which is used as a febrifuge: the *Picroshiza*, is a plant allied to speed well, and grows at from 12,0 0 to 15,000 feet elevation, and is a powerful bitter, called "Hoonling" by the Tibetans.—*Hooker Him. Jour Vol.* 1 *p.* 272.

(6329) PICRORRHIZA KURROOA. (Syn. Veronica Lindleyana, Wal. Cat.) Grows in Gosainthan, Kemaon, and Kedarkanta. A fleshy, rooted perennial. Flowers sessile, deep blue, in dense spikes. The root is intensely bitter, and used as a medicine in India.—*O'Shaughnessy p.* 478. This plant grows on the hills of Hindostan, as also in the Cashmerian mountains, and the root is much in use at Lahore; but more in veterinary than in human medicine.—*Dr. Honigberger, p.* 335.

(6330) PICTURE PLANT, Graptophyllum hortense, Justicia picta: variegated leaf: blood red leaf. The justicia, one variety of which has variegated leaves, and the other deep purple, is multiplied throughout the Tenasserim Provinces.—*Mason.*

(6331) PIENCHE, the Tamil name of a Ceylon tree which is of a dark colour and very heavy and close-grained. It grows to about twelve inches in diameter, and fourteen feet in height. From this tree the native carpenters make the frames of vessels, it being considered durable: it produces a fruit which is of no use.—*Edye, Ceylon.*

(6332) PIERARDIA. Of this genus, Wight gives Courtallensis, 1972-13; macrostachys, 1912-13.

(6333) PIERARDIA SAPOTA.

Kanayœ, Burm.

Plentiful in the Pegu and Tounghoo forests, as well as about Rangoon. Dark brown wood. —*McClelland.*

(6334) PIGEON PEA is the seed of the plant called by Linnæus *Cytisus Cajan*, and by De Candolle *Cajanus bicolor* and *Cajanus flavus*. It is a kind of pulse highly esteemed by all classes of the natives of India, and is by them regarded as holding the third rank among such articles of food. —*Eng. Cyc.* See Cajanus Indicus.

(6335) PIGMENTS. In illustration of the variety of indigenous pigments, says Dr. Cleghorn, I may state that finding my colour-box becoming exhausted, I have been enabled to supply, on more than one occasion, all its deficiencies without difficulty from the natural products of the surrounding forests of the Malabar Ghauts, including yellow from the *Garcinia*, blue from various species of *Indigofera*, red and purple from *Oldenlandia umbellata*, *Pupplaychukkay* (*Ventilago* ?) and *Vatica laccifera*.

(6336) PIMELEA. A species of this plant is abundant in the Wynaad, where its fibre is made into sewing thread by the Natives. The plant is common all over the Neilgherries.—*McIvor, M. E. J. R.*

(6337) PIMELEA SPECTABILIS. Thymelaceæ. These are a beautiful genus of shrubby plants, growing to the height of two or three feet, they require a rich soil, and if carefully watered, produce numerous heads of flowers, the colours are white, red, rose and yellow, readily cultivated from seed.—*Riddell.*

(6338) PIMENTA VULGARIS. The "Allspice" tree, introduced from the West Indies. Several large trees are at Madras, but the cli-

mate of the Carnatic does not seem to suit them. —*Hort. Gyneu.* 46. *M E.J.R.* The pimento, *Eugenia Pimenta* (*Myrtus Pimenta*), is a native of Mexico, and the West Indies. It flourishes spontaneously and in great abundance on the north side of the Island of Jamaica; its numerous white blossom mixing with the dark green foliage, and with the slightest breeze diffusing around the most delicious fragrance, give a beauty and a charm to nature rarely equalled, and of which he who has not visited the shady arbors and perfumed groves of the tropics can have little conception. This lovely tree, the very leaf of which when bruised emits a fine aromatic odor, nearly as powerful as that of the spice itself, has been known to grow to the height of from 30 to 40 feet, exceedingly straight, and having for its base the spinous ridge of a rock, eight or ten feet above the surface of the hill or mountain. A single tree has frequently produced 50 lbs. of the raw, or 100 lbs. of the dried fruit. The fruit has an aromatic odor, and its taste combines that of cinnamon, nutmeg, and cloves; hence its common name of allspice. The fruit of *Eugenia acris* is used for pimento. The trunk is of a grey color, smooth and shining, and altogether destitute of bark. It is luxuriantly clothed with leaves of a deep green, somewhat like those of the bay tree, and these leaves are, in the months of July and August, beautifully contrasted and relieved by an exuberance of white flowers. The leaves yield by distillation a delicate odoriferous oil, which is said to be sometimes passed off for oil of cloves. The berries are gathered before they are ripe, and spread on a terrace, exposed to the sun for about a week, during which time they lose their green color, and acquire that reddish brown tint which renders them marketable. Some planters kiln-dry them. Like many of the minor productions of the tropics, pimento is exceedingly uncertain, and perhaps a very plenteous crop occurs but once in five years. In 1800 there were 12,759 bags and 619 casks of pimento imported from Jamaica; in 1824 there were 33,398 bags and 599 casks shipped from the island; in 1829 the quantity exported was 6,069,127 lbs. In the year ending October 1843, the export of pimento from Jamaica was 29,322 bags and 156 casks; in the year ending October 1844, 12,055 bags and 88 casks; in the year ending October 1845, 233 casks, valued at 30s. each, and 59,494 bags, valued at 20s. From 1st January to 1st August, 1851, 128,277 lbs. pimento were shipped from the port of Montego Bay, Jamaica. There was a very considerable pimento plantation made in Tobago, some years ago, by a Mr. Franklin, but it was abandoned by his sons, that they might attend the more exclusively to sugar culture. —*Simmonds.*

(6339) PIMPINELLA, a genus of Umbelliferus Plants inhabiting the meadows and mountains of Europe principally, is chiefly interesting on account of its comprehending among its species the Anise of the shops. This plant is an annual, with a smooth stem, one to one and a half foot high; the lower leaves roundish, cordate, lobed, and both serrated and cut; those of the stems pinnated with wedge-shaped lanceolate segments, and the upper trifid, with the lobes undivided and leaner. The flowers are small and white. The fruit is narrow, slender, rather hairy, with five filiform ridges to each pericarp. The latter is employed extensively as a carminative medicine, and for the purpose of flavouring liqueurs. The plant inhabits Egypt and the islands of the Grecian Archipelago, especially Scio.—*Eng. Cyc.*

(6340) PIMPINELLA ANISUM, Aniseed. (Ανισον. Dioscor.) Egypt, Scio, Levant. Lin.

Somboo, Tam.	Sonf, Hind.
Anisa, Guz.	Aneesoon, Arab.
Sonf, Duk.	Sataphuspha, Sans.
Razyanchroomee, Pers.	Mahoree, Beng.

Aniseed in various forms is much employed in medicine as a stomachic, especially in the diseases of children, and is also used as a condiment among all eastern nations. The seeds are often fraudulently mixed with clay, are liable to spoil by spontaneous fermentation in the packages. They are much richer in essential oil than the majority of the Umbelliferæ, 8 lbs. having given 3½ ounces of the oil —*O'Shaughnessy, p.* 358.

Essential Oil of Aniseed.—Is white, yellowish, a little lighter than water, congealing at 78 Fahr. into a soft mass, sp. gr. 0.985. It is liable to adulteration with spermaceti and several fixed oils, some of which may be detected by alcohol, all by leaving a greasy stain on paper when evaporated over a lamp. This oil contains nitrogen according to the analysis of Saussure. It only exists in the pericarp, the interior of the seed yielding a tasteless and inodorous fixed oil. This is often mixed with the essential oil, and is as much an adulteration as if castor or olive oil had been employed. The pure essential oil can only be obtained by distilling the seeds with water. The oil is a good and safe stimulant, and is much used in prescriptions for children suffering from flatulence and colic. (See Essential Oils.)—*O'Shaughnessy, p.* 359.

(6341) PIMPINELLA CANDOLLEANA, 341; involucrata, 335-567; Leschenaultii, 1005. Are given in Wights Icones.

(6342) PINCHBECK, Petit, or Similor.

Tombak, Dut.	Wellaety-Soona, Guz.
Similor, Tambac, Fr.	Hind.
Tomback, Ger.	Tombacco, It.
	Tambac, Tambaga, Sp.

A name given to one of the many imitations of gold, consisting of zinc combined in various proportions with copper or brass. It is frequently used as a substitute for gold, in the formation of watch-cases, rings, chains, lockets, &c. —*Faulkner.*

(6343) **PINE APPLE.** BROMELIA ANANAS. ANANASSA SATIVA.

Nanat, BURM.	Nanas, MAL.
Anasi, CHIN.	Koida chocka, MALEA.
Ananas, GUZ. & HIND.	Anasie-pullum, TAM.
Anasso, IT.	Ananas-puudoo, TEL.

A well-known succulent fruit of a tropical plant (*Ananassa sativa*), indigenous to America, and the East and West Indies, and now reared in hot houses in England. In its aboriginal state, it is inferior in every respect than when carefully cultivated, which may account for the superiority of the English pine apples. *Pine Apples* are perhaps the best of all the cultivated fruits of Pegu, and they require so little care, that they are brought into market in Rangoon in vast quantities of the finest quality from the end of April until the middle of August. In the upper parts of the province, about Prome and Tounghoo, they are scarce.—*Mc Clelland.* One of the most abundant fruits in the Tenasserim Provinces is the pine apple, also an American production. With the plant, the native American name appears to have been introduced into Burmah, for *nanas* is said to be the name it had among the Peruvians where it was originally found, and the Burman name is *nanat*; which the Sgaus have abbreviated to *nay*.—*Mason.*

The *Pine Apple Tribe* or *Bromellaceæ*. The Bromel worts, or the Pine apple tribe is a natural order of Endogens, consisting of dry herbaceous plants, remarkable for their hardness and dryness of foliage. The flowers of most are pretty, and some of them, remarkably handsome and sweet scented; but except in the genus "*Ananassa*" the fruit is in no case of any value: the order contains 23 genera and 130 species.—*Eng. Cyc. p.* 669. The Pine-apple, or Ananas, is one of this tribe of plants, and is an object of the most careful culture in Europe, on account of its pleasantly sweet and aromatic fruit. Its long and rigid leaves, which are thorny at the edges and point, abound in a quantity of fine white fibres, which are, in some countries, woven into the finest fabrics, netted or twisted into lines for fishing and into ropes possessed of considerable strength. These are said not to be injured by constant immersion in water—a property which the natives increase by tanning them. The Pine-apple (*Ananassa sativa*, formerly Bromelia Ananas), being a native of the moist forests of South America, from the level of the sea to elevations of about 1800 feet, requires, for its successful culture as a fruit, a warm and moist climate; but, like others of the family, the species are capable of existing in a warm, dry air. The Pine-apple is said to have been introduced into India by the Portuguese, in the year 1594. It has, in some parts, become so naturalised, as to appear indigenous. Capt. Turner, in his journey to Teshooloomboo, mentions it as very abundant at the foot of the Himalayas. It flourishes in Assam, and forms thickets near Rangoon, producing, also, according to the accounts of different visitors, very juicy, well-flavoured fruit. Dr. Wallich, in the year 1836, presented to the Agricultural Society, a bag made on the Khasia Hills, of Pine-apple fibre, having purchased it for a trifle at Cheraponjee. He mentions the enormous quantity of Pines grown on that range, and Dr. Oxley writes that thousands of acres of pine-apple plant, cover the adjacent islands, so that the supply might be considered inexhaustible, of a fibre remarkable as well for fineness as for strength.—*Royle Fib. Pl. p.* 377

Pine Apple or *Pina Fibre*, or *Bromelia*. The leaves of several plants, of the genus and family (*Bromeliaceæ*,) to which the cultivated pine-apple, ananassa sativa, belongs, abound in fine white fibres very soft, silky and pliant, as long in the stalk as flax and can be worked up with the same machinery. In some countries it is woven into the finest fabrics, netted or twisted into lines for fishing and into ropes possessed of considerable strength. These are said not to be injured by constant immersion in water—a property which the natives increase by tanning them. The Pine-apple being a native of the moist forests of South America, from the level of the sea to elevations of about 1800 feet, requires, for its successful culture as a fruit, a warm and moist climate; but like others of this family the species are capable of existing in a warm, dry air. The Pine-apple is said to have been introduced into India by the Portuguese, in the year 1594. It has, in some parts, become so naturalised, as to appear indigenous. Capt. Turner, in his journey to Teshooloomboo, mentions it as very abundant at the foot of the Himalayas. It flourishes in Assam, and forms thickets near Rangoon, producing, also, according to the accounts of different visitors, very juicy, well-flavoured fruit. Dr. Wallich, in the year 1836, presented to the Agricultural Society, a bag made on the Khasia Hills, of Pine-apple fibre, having purchased it for a trifle at Cheraponjee. He mentions the enormous quantity of Pines grown on that range, and that the plant appears as if it were quite a natural production. Dr. Helfer describes the Pine-apple as so abundant in the Tenasserim provinces as to be sold in Amherst Town in the months of June and July at the rate of one rupee for a boat-load. It chiefly abounds in low grounds, though it is also to be found in the hills amongst the Karens. The natives know it only by the American name, which they transform into *Nannah thi*—thi designating fruit. They do not seem to be acquainted with the beautiful fibre yielded by the leaves. The Pine-apple is described as growing in great abundance in the Philippine Islands, but as producing only a small, rather dry fruit. But we require some precise information to enable us to judge whether

this is actually the plant escaped from cultivation. M. Perrotet considers it a distinct species, and has named it *Bromelia Pigna*, from the Spanish name *Pigna* or *Pina*, signifying a cone. There, this wild plant is valued on account of the fine hair-like fibres which are separated from out of the leaves. Of these fibres, the celebrated pine-apple cloth of the Philippines, sometimes called "batiste d'ananas," and resembling the finest muslin-like fabric, is woven. This is embroidered by the nuns of the convents in Manilla, with great skill and taste. Some beautiful specimens of these, under the name of Pina muslin, were to be seen in the Exhibition of 1851. This is sometimes called grass-cloth, but erroneously. With a magnifier the fibres may be seen to be very numerous and fine, but not twisted at all, as in grass-cloth or the finest muslins and cambrics. Mr. Bennet, in his 'Wanderings,' observes that one of the coarser fibres may be subdivided into threads of such fineness as to be barely perceptible, yet sufficiently strong for any purpose. Mr. Bennet mentions visiting a plantation near Singapore, made by a Chinaman, for the preparation of the fibres of the ananas or wild pine-apple, which are exported to China, being used there "in the manufacture of linens." The Chinese said he got 1½ rupees the catty, for the fibre. The leaves recently gathered—and the largest are preferred—are laid upon a board and the epidermis is removed with a broad knife. Upon its removal from the upper surface of the leaf, the long and beautiful fibres were seen lying upon the lower and denser epidermis, running in a longitudinal direction; the fasciculi of fibres were then readily detached by the hand, on being raised with the broad knife. The separation of the fibre of the ananas is practised in other places besides the Philippine Islands. The Singapore Committee forwarded specimens (*Talinanas*) from Malacca, as well as some of three different qualities prepared at Singapore, and a portion as ready for weaving, that is, with the ends gummed, or joined together by some adhesive substance; thus forming the "invisible knots" of an old author. Specimens were also sent from Java and the island of Celebes. Dr. Roxburgh does not appear to have paid much attention to the separation of the ananas fibre; but in the year 1839, Miss Davy sent specimens of a thread prepared from the wild pine-apple plant of Assam, of various degrees of fineness, observing that the thread must be prepared when the leaves are green, as nothing can be done with them in a dry state. Miss Davy subsequently sent specimens of cloth manufactured from this thread to the Agricultural Society of Calcutta, observing that she had had much difficulty in getting it woven, as the principal manufacturers in Dacca positively refused to undertake making it into cloth. A weaver in the jungles near Dacca, afterwards undertook to do so, and wove the cloth which was sent. Of this, Miss Davy had some embroidered in silver,—a style of work in which the natives of that part of the country excel. The specimens of the fibre were shown by Mr. E. Solly to spinners in England, but who did not consider it would be substituted for flax in the manufacture of textile fabrics. A patent was, however, taken out by Mr. Zincke, for the manufacture of thread from this fibre, because, when bleached, it could be spun in the same way as flax. The process of bleaching, by destroying the adhesion between the bundles of fibres, renders it much finer; and hence enables it to be extended between the rolls in the process of spinning. He considers that from its beautiful silky lustre, combined with considerable strength, it is well adapted to form a substitute for linen. Pine-apple fibres (*anasa nára*), and the tow or oakum from them, were also sent to the London Exhibition of 1851, from Madras and from Travancore, showing that the art of separating these fibres is extensively diffused. Dr. Hunter received some very fine, strong, and silky fibres from Porto Novo, prepared by Mr. Lima. Besides the fibre, some twine and cord made with it was also sent from Madras and from the Eastward. Mr. Bennett says, that at Singapore, from the cost of labour, the pine-apple fibre could not be prepared under thirty-eight or forty dollars the pecul; but in Penang, or other places where labour is cheap, and women and children could be employed upon it, the expense would hardly exceed ten dollars per pecul. In the experiments which Dr. Royle made with these various fibres, a certain quantity of those prepared at Madras bore 360 lb., while a similar quantity from Singapore bore 350 lb. before they broke; but of New Zealand flax the same proportions bore only 260 lb. In a report from the Arsenal of Fort William, dated June 3d, 1853, the results are given of some experiments made by Conductor Wilkins on several kinds of rope manufactured by Messrs. W. H. Horton and Co., of Calcutta; and among these there is one of Pine-apple fibre, of three inches and a quarter in circumference. The Government proof is that a rope of this size should bear a weight of 42 cwt., but it bore no less than 15 cwt. more, that is, it broke with a weight of 57 cwt. ('Journ. of Agric. Soc. of India,' vol. viii, p. 182); proving incontestably that Pine-apple possesses strength for cordage, as well as fineness for textile fabrics.—*Royle Fib. Pl. p.* 87.

(6344) *Bromelia. Pinguin*, or "Broad leaved wild ananas," is common in Jamaica and other West India Islands. Its leaves yield a strong fibre, which is made into cloth of which they make hammocks, and twisted into ropes. Amongst others Bromel worts may be mentioned, *B. karatas*, or "upright leaved wild ananas," common in South America, *B. sagenaria*, common on the coasts near Pernambuco, also *B.* (*now Billbergia*) *vari-*

egata, yields excellent twine for nets in Brazil: and the so called New Orleans moss or "longbeard" of which a bale was sent to the Exhibition in 1851, and proposed as a substitute for hair for stuffing chairs, cushions and mattresses.

(6345) PINE NUTS, (Neoza Chilghoza. from N. W. India, Caubul, &c. See Pinus Gerardiana.

(6346) PINNOTHERIDÆ, a family of the Brachyurous Crustacea called Pinnotherans by Milne Edwards, known by the Common name of Pea-Crabs; of these *Elamena* (M. Edwards) is founded on *Hymenosoma Mathæi*, figured by M. Ruppell, in his work on the 'Crustacea of the Red Sea' and separated from that genus by Mr. Milne-Edwards, who thinks that it seems to establish the passage between the *Hymenosomata*, the *Oxystomes*, and the *Oxyrhyncki*.

E. Mathæi (Ruppell, 'Krabben,' pl. v. f. 1), is found in the island of Mauritius and the Red Sea.

(6347) PINS.

Epingles, Fr.	Tauck nec, Guz., Hind
Stecknadeln, Ger.	Alfeen, Hind.

Well-known little instruments, manufactured on a large scale in Birmingham, Warrington, Sheffield, Gloucester, and London.—*Faulkner.*

(6348) PINUS, a genus of Gymnospermous Exogenous Plants, consisting for the most part of timber trees, inhabiting various temperate countries in the northern hemisphere. They are commonly called Pine-Trees, and are distinguished from the Firs by their leaves, always evergreen, and needle-shaped, growing in pairs, threes, fours, or fives, surrounded by a membranous sheath at their base. In reality each parcel of leaves indicates a small branch axillary to a membranous, deciduous, withering leaf. The species are generally of great beauty as objects of ornament, or of much value on account of their timber, and are in much request by the planter: on which account we give a very brief enumeration of the best known species.—*Eng. Cyc.*

(6349) PINUS or CEDRUS DEODARA, leaves and twigs used in native medicine. Kelon, *Hind.* the most celebrated of the Himalayan pines, noticed by Avicenna, found in Nipal, Kemaon, Kashmere, at 7,000 to 12,000 feet. *Prod.* A turpentine called *Kelon ka tel*, used as a stimulant to foul ulcers.—*O'Shaughnessy, p.* 612.

(6350) PINUS EXCELSA, Wall. Pl. Rar. t. 201. Narambetty, Nipal, Simla, Bootan. *Kuel* of Sirmoor and Gurhwal, resembles the Weymouth pine, and is remarkable for its drooping branches.—*O'Shaughnessy, p.* 612.

(6351) PINUS EXCELSA.

Tongschi, Chin.

Though common in Bhotan, is, as I have elsewhere remarked, not found in east Nepal or Sikkim; the wood is admirable, being durable, close-grained, and so resinous as to be used for flambeaux and candles.—*Hooker Him. Jour. Vol.* II. *p.* 45.

(6352) PINUS GERARDIANA. Neoza chilgoza of Elphinstone. The Neoza Pine. Trunk lofty, with a conical head. Leaves 3, short, stiff, glaucous, obsoletely serrated, with deciduous sheaths. Cones very like those of *P. longifolia*. Seeds large, eatable. A native of the coldest forests of the Himalayas.—*Eng. Cyc.* The seeds form one of the principal articles of subsistence in Kunawur.—*O'Shaughnessy, p.* 613.

(6353) PINUS HALEPENSIS, the Alleppo Pine. Trunk slender, erect. Leaves 2, long, slender, light green. Cones ovate, stalked, solitary, very regular in form, with depressed truncated scales. A beautiful species, found wild in the western parts of Europe, from Genoa to Constantinople, and also throughout Syria. It grows fast, and is at once known by its fine light-green foliage; but its wood is not of much value, and it bears the climate of England with impatience.—*Eng. Cyc.*

(6354) PINUS LATTERI. Some twenty years ago the residents of Maulmain were not a little surprised to find, among the drift wood of the Salwen, a log of some coniferous tree. This was the first intimation that any tree of the pine tribe grew on the borders of these Provinces; but whether it were of the genus pinus, or abies, or larix—a pine, a fir, or a larch, did not appear. It was several years after this occurence, that a commissioner told Mr. Mason, he had offered a hundred rupees to any of the foresters who would bring down a spar of this tree. Spars have been since brought down, but it is believed that Capt. Latter was the first European to visit the locality where the tree is indigenous, and from specimens of the foliage and fruit, which he brought away, it appears to be a new species of pine that may be characterized thus:

P. Latteri. Arbor 50—60 pedalis, cortice scabro, foliis geminis 7—8 uncialibus caniculatis serratis scabbriosculo, strobilis 4 uncialibus ovato-conicis, squamis rombeis inermis.

Hab. In provincia *Amherst*: in convalli fluvii *Thoungyeen.*

Descr. A tree from 50 to 60 feet high, or more and from 1½ to 2 feet or more in diameter. Sheaths of the leaves arranged spirally, tubular, membranous.—*Mason.*

(6355) PINUS LONGIFOLIA. Himalayas.

Cheer, sullah, surul, thanaa, Hind.

The Long-Leaved Pine. Trunk erect, with a coarse rugged bark, and whorled branches.

Leaves very long, drooping, slender, bright-green, channelled, and serrated. Cones shorter than the leaves, oblong ovate, woody, and rugged, with pyramidal obtuse, mucronate, corky, recurved scales. Seeds large, eatable. An Indian species inhabiting the valley and lower hills of Nepaul, (*Eng. Cyc*): also the Entrance to Nipal in the Kheree Pass, along Touse and Jumna rivers, at elevations of 5,000 and 6,000 feet. *Produce*, gunda biroza, birje or cher ke gond. Birozehtur, *Pers.* same name also given to Indian olibanum.—*O'Shaughnessy, p.* 612. This pine is called by the Lephas "guiet-koong," and by the Bhoteeas "Tea-dong" in Sikkim only: it grows in low valleys, where better timber is abundant—*Hooker, Vol.* II. *p.* 45. The scenery of the valley Nyong in East Nepal is the most beautiful in the lower Himalaya: the Cheer Pine (*P. longifolia*) is abundant, cresting the hills, which are loosely clothed with clumps of oaks and other trees, bamboos, and bracken (*Pteris.*) —*Hooker. Him. Jour. Vol.* 1. *p.* 182.

(6356) PINUS SINENSIS, the Chinese Pine. A large tree. Leaves 3, slender, deep green, serrulated. Cones ovate, brownish, on short stalks, with flattened truncate, unarmed scales. Native of China. Very little is known of it, except from Chinese drawings. In England it only exists in the garden of Mr. Weels. of Redleaf, near Tunbridge, where it is found to be 'tolerably hardy.'—*Eng. Cyc.* It is repeatedly noticed by Mr. Fortune. He says, *Pinus Sinensis*, is met with on the sides of every barren hill, both in the south and north of China, and is generally badly used by the natives. —*Fortune's Tea plants, page* 7. The Chinese pine (Pinus sinensis), which is grouped about in all directions, attains to a great size. Many of these hills are well wooded. I remarked as we went along good forests of Chinese pine (Pinus sinensis), the Japan cedar (Cryptomeria Japonica), and the lance-leaved fir (Cunninghamia lanceolata). The forests of the Japan cedar and the lance-leaved fir were extremely picturesque and beautiful. The trees generally were young and not remarkable for size but were growing vigorously, and likely, if allowed to stand for a few years, to make valuable timber. In addition to this consideration, there was a symmetry and grace in the general appearance of these forests which one rarely sees in temperate climates, if we except perhaps the Himalaya mountains.—*Fortune's Res. p.* 189.

(6357) PINNAY, Calophyllum Inophyllum.

(6358) PINEY VARNISH TREE. VATERIA ROXBURGHIANA. Trees which yield this beautiful varnish so extensively used in Hindustan, are very common about Maulmain, yet I am not aware that the varnish is collected.—*Mason.* The tree grows from cuttings and is found planted by the road side in Malabar. The resin or substance as it flows from the tree, applied while in its fluid state, makes a good varnish called Peiny varnish in the Malabar coast, and there, the tree is commonly called the Peiny varnish tree, or Peiny maram. It is mentioned by Dr. Buchanan in his Journey through Mysore, Canara and Malabar. In Vol. 2 P. 476, he says some men of the Panchala tribe, which here is called Peninglan, paint and varnish by the following process. They take butter milk and boil it with a small quantity of quick lime until strings form in the decoction, and separate from the watery parts, which they decant. The stringy matter is then mixed with the paint, which has been well powdered: with these the wooden work is first painted, it is then allowed to dry for one day, and afterwards receives a coat of Pundum, which is the fresh juice of a tree called Peiny Marum. The Pundam must be used while it is fresh and will not keep for more than two or three days after the first coat of paint is given, and that is followed by another of varnish. In the same manner leather may be painted and varnished. The varnish effectually resists the action of water. A valuable Tallow, which has lately been sold in England at 44s. 6d. the pound, nearly equal to the price of the best Russian Tallow, is prepared by boiling the seeds in water: it is said to be free from any disagreeable smell—*Rohde. M.S.S.*

The *Vateria Indica* (*Chloroxylon Dupada*, Buchanan and Ainslie, and Pinney marum of the Hindoos) produces a resin resembling Copal, much finer than that procured from the other species, natives of India, the finer specimens of which are as transparent as amber and nearly colourless. It is procured by the very simple process of cutting a notch in the tree, sloping inwards and downwards. This is soon filled with the juice, which in a short time hardens by exposure to the air. When used as a varnish the usual practice is to apply the balsam before it has become hard: but when that is not procurable the resin melted by a slow heat and mixed with boiling linseed oil forms a varnish which answers equally well for most purposes. As this varnish is of the finest description, the following formula for its preparation may prove useful to some who are unacquainted with the process. Into a new and perfectly clean earthen vessel (a chatty) put one part of the Piney dammer, in coarse powder, cover closely, and apply a *very gentle* heat until the whole is melted; then add about two parts of linseed oil, nearly boiling hot, and mix well with a wooden spatula. Should the varnish prove too thick it can at any time be reduced by the addition of more oil, or, if required, may be made thicker in the first instance. It is essential to the success of the process that the Piney be melted in a covered vessel over a very slow fire, and the whole of it reduced to a fluid before the addition of the oil, which must, to

ensure an equal mixture, be nearly boiling hot. This varnish is used for carriages and other fine furniture requiring to have their paint well protected, or to which it is desirable to impart a fine gloss. A spirit varnish is prepared by reducing to powder about six parts of Piney and one of Camphor, and then adding hot alcohol sufficient to dissolve the mixed powder. Alcohol does not dissolve Piney without the aid of the Camphor, but once dissolved will retain it in solution. The varnish thus prepared is employed for varnishing pictures, &c., but before being used requires to be gently heated to evaporate the Camphor, which otherwise will produce by its after evaporation a roughness and inequality on the surface of the picture, and spoil its appearance.—*O'Shaughnessy page* 755.

(6359) PINEY TALLOW or DOOPADA OIL. Vateria Indica.

Piney Yennai Tam. | Doopada Nunee, Tel.

This most valuable tree, which, besides the product under consideration, yields a Resin nearly equal to copal, and an excellent building wood, grows plentifully in the jungles of the Western Coast. The oil, which is perfectly solid even in hot climates, is prepared by cleaning the seeds, then roasting and grinding them into a mass. To 5 seers of seed, add 12 seers of water, and boil until the oil rises to the surface. Remove the oil, stir the contents of the vessel, and allow it to stand until the following day, when more oil will be observed on the surface, which may be collected and the process repeated. The oil is principally used for lamps, but is very suitable for soaps and candle making.—*M. E. J. R.*

(6360) PIPECLAY. A very plastic and tenaceous kind of clay, of a grayish, or yellowish-white colour, found near Poole in Dorsetshire, in the Isle of Purbeck, and in many places in India. It is manufactured into tobacco pipes; and is besides used as the basis of the queens's-ware pottery, as well as a detergent by scourers of cloth.—*Waterston. Faulkner.*

(6361) PIPER, a genus of Plants belonging to the natural order *Piperaceæ*. It has stamens varying in number from 1 to 10; stigma 3-lobed; fruit baccate. Wight gives in Icones Piper arborescens, 1940; argyrophyllum, 1941; attenuatum, 1933; hymenophyllum, 1942; Nepaulense, 1938; nigrum, 1934; Sylvestre 1937; trioecum, 1935-6; Wightii, 1939.

(6362) PIPER BETLE, Linn. Roxb. Fl. Ind. i. p. 158. Bot. Mag. t. 3132 φυλλον μελαβαθρον *Dioscor.*—*O'Sh.*

Vettilay, Tam.	Pan, Hind.
Pan, Duk.	Tamalapakoo, Tel.
Tanbool, Arab.	Bargi tambol, Pers.
Tambuli, Sans.	—*Ainslie.*

The leaves of this and P. Siriboa are extensively used by the natives of the East Indies and lately the West, to chew along with the nut of the *Areca catechu* and quicklime, as a restorative of the powers of the stomach and promoter of digestion. It is capable however of producing, like some other species of *Piper*, intoxicating effects, and should be used in moderation.—*Eng. Cyc.* Piper Betle in Pegu, grows both in a wild and cultivated state. It is cultivated in small quantity for domestic consumption in every part of the province, except the Tharawaddy district, and grows wild in the Pegu Forests, on the Cadoojway Choung.—*McClelland.*

(6363) PIPER CUBEBA. Cubebs. Lin.

Val mellaghoo, Tam.	Salava mirialoo, Tel.
Kubab-chinie, Hind.	Kababah, Arab.
Dumke mirchie, Duk.	Suganda marichi, Sans.
Komoon koos, Malay.	

A native of Java. Powdered Cubebs given in doses of one to two drams, in water or milk, is employed in Gonorrhœa with almost certain success; according to Blume, the Piper Caninum which corresponds with the P. Cubeba of Rox., Fl. Ind. 1. p. 164, is also a native of Java, and the chief source of the Cubebs of commerce.—*O'Shaughnessy, p.* 574. The fruits of both are stalked, but that of the former is larger and has more pungency than the latter. Both are common in Java, where, as in other parts of India, they are used as a grateful condiment, as common pepper is in Europe. They are also employed medicinally in the same complaints as give them repute in Europe. The berry is small, about the size of black pepper-corns (but with a little foot-stalk, from one-third to half an inch long, hence called sometimes *P. caudatum* or *P. pedicellosum*, more or less round, of a blackish-gray or grayish-brown colour, with a thin vascular reticulated husk, which incloses a hard round oily seed. The husk has a pleasant taste; the seed a bitterish, acrid, peppery, aromatic, and camphor-like flavour. Those which come from the islands of the Indian Archipelago are the best. A sort from the Mauritius, small, or about the size of a millet-seed, are from some unknown species. The Guinea or African cubebs is the produce of *P. Afzelii*. Indian cubebs are frequently adulterated with black pepper, pimento berries, or the fruits of the *Rhamnus catharticus*. Genuine cubebs consist of waxy matter, two kinds of volatile oil, a peculiar resin (cubebin), balsamic resin, &c. The volatile oil by rest deposits a camphor, which crystallizes in four-sided plates. The resin is analogous to that of copaiva, and has, like it, a peculiar influence over mucous membranes especially those of the urino-genital-organs.—*Eng. Cyc.*

(6364) PIPER LONGUM, Long pepper. *Roxb. Fl. Ind.* i. p. 154.

Pipilie, Tam.	Pippali, also Krishna, Sans.
Pipuloo, Tel.	Dar filfil, Arab.
Pipilie, Duk.	Filfil-i-Daraz, Pers.
Pipel, Hind.	

Piper Longum, Long Pepper, is a native of the East Indies, the female spike of which having attached to it the dried half-ripe berries (resembling the catkin of the birch), is used in medicine. It has nearly the same chemical composition and properties as black pepper, though feebler. It is said to contain piperin. The root is employed by the Hindoos, but it is still weaker than the fruit.—*Eng. Cyc.* This grows wild in India, along water-courses towards the Circar mountains, but is much cultivated. Root (Granthicka, *Sans.*) sliced and dried constitutes the *Pippula moola* of the native druggists, a substance much used as a stimulant remedy and spice. The analysis of the fruits of the long pepper corresponds closely in results with those of the *Piper* nigrum.—*O'Shaughnessy, p.* 575. Long Pepper is a creeper of easy culture and should be trained on poles, or have strong sticks to grow upon. It is common in all parts of India.—*Jaffrey. Long Pepper* (Piper longum, Lin.) is extensively cultivated in the Northern Circars, its use is rather limited; as in the commercial returns it is always included with black pepper, the quantity cannot be ascertained.—*M. E. J. R.*

(6365) PIPER METHYSTICUM. Ava pepper. A native of the Society, Friendly, and Sandwich islands, where it is called "Ava;" used in a tincture in chronic rheumatism, and in infusion as an intoxicating beverage, which is also deemed antisyphilitic. To cure venereal, the patient drinks an infusion until he become drunk, after which copious perspiration ensues. *O'Shaughnessy, p.* 575.

(6366) PIPER NIGRUM, Willd: BLACK PEPPER. Hip.

Mellaghoo, TAM.	Gol murch, HIND.
Gammiris, CING.	Kala murch, DUK.
Merialoo, TEL.	Filfil Uswud, ARAB.
Marchu, SANS.	Filfil-seeah, PERS.

A native of Malacca, Java and Sumatra, cultivated all along the Malabar Coast. Dr Roxburgh describes it as being found wild among the hills of the Rajamundry district—*Ainslie, p.* 265. *O'Sh. page* 571. Piper Nigrum, Linn, Black Pepper, a climbing plant of the East Indies, and very extensively cultivated there, the plantations stretching from 98° to 115° E. longitude, and S. lat. to 12° N. lat. which limits comprise Penang, Sumatra, Borneo, the Malay Peninsula, and all lands to the east of the Gulf of Siam. The best, perhaps the only, comes from Malabar, the least esteemed from Java and Sumatra. The plant is allowed to grow, trained to the stem of the *Areca catechu*, and other trees, especially the Jack (*Artocarpus*) and *Hyperanthera moringa* (or Horse-Radish Tree), four years before the fruit can be collected. The berries are gathered when yet green, before they are perfectly ripe, and quickly dried on mats, by which they turn black. When plucked too young, they speedily fall into a state of powder. These are separated from the others by sieves and winnowing. In this condition it is termed black pepper. White pepper is the same fruit freed from the outer rind: for this purpose, the ripe berries are allowed to macerate in water, and the husk is removed. These are smaller, smooth, of a greyish-white colour, varying to yellow, with a less powerful odour and taste than the black.—*Eng. Cyc.* Although principally the produce of the Eastern islands, it is grown of a superior quality in the Malabar coast. The root is a tonic and cordial.—*Riddell.* Black pepper (piper nigrum) and long pepper (piper longum) grow wild in considerable quantities in the hilly tracts of Goodem, and probably along the whole of the pestiferous range of the Eastern Ghats The latter finds its way in small quantities down to the bazars on the coast, but the black pepper is entirely neglected, and does not appear to be gathered even for local use.—*M. C. C.*

(6367) PIPER NIGRUM AND PIPER LONGUM. BLACK PEPPER AND LONG PEPPER. These substances appear to have been used as febrifuges in the east from the earliest periods. The powder and the root of long pepper have been much employed in Hindu medicine.—*Ind. Ann. Med. Sci. for Apl. p.* 394.

(6368) PIPER SYLVATICUM. Roxb. Fl. Ind. i. p. 156. N. W. Mountains of Bengal, (*Pahari pippul,*) used while green, and ripe also, as long pepper.—*O'Shaughnessy, p.* 575.

(6369) PIPER TRIOECUM. Roxburgh. Fl. Ind. i. p. 154.

Mirial tiga, TEL.

Circar mountains, in shady places, with rich soil, fruit succulent, small, round, red, excessively pungent, an article of important commerce from Madras.—*O'Shaughnessy, p.* 575.

(6370) PIPPALLY CATTY, the dried long pepper vine.

(6371) PIPRINÆ, Mr. Swainson's name for the Manakins, which he makes a sub-family of the family *Ampelidæ*, Fruit-Eaters, or Chatterers, and thus characterises:—Size small. Feet lengthened, slender, weak. Bill very short: the upper mandible much curved. Mr. Swainson is of opinion that the *Piprina*, called Manakins from their diminutive size, which is seldom larger than that of a tom-tit, constitute the sub-typical group of this family.

(6372) *Phœnicurus, Pipra* (with its sub-genus *Stiopia*), *Calyptura*, and *Pardalotus*, are the genera arranged by Mr. Swainson under this subfamily.

(6373) PIPTANTHUS NEPALENSIS. Amongst the plants on the Tendong in Sikkim, conspicuous is the beautiful laburnum-like *Pip-*

tanthus Nepalensis, with golden blossoms, —*Hooker. Him. Jour. Vol.* II. *p.* 5.

(6374) PIRI, the Tamil name of a Ceylon tree which grows to about twenty feet in height, and two feet in diameter. It is very close in its grain, and is used by the natives for the frames of vessels and in house-work. It produces a fruit which is of no use.—*Edye, Ceylon.*

(6375) PISONIA GRANDIS, NYCTAGINEÆ, Riddell.

Bag-Achera, DUK.

A straggling shrub, armed with strong axillary recurved thorns; flowers small, in axillary terminal panicles. Forms an excellent hedge plant.

(6376) PISONIA INERMIS.

Kongi-putri, DUK.

Without thorns.

(6377) PISONIA MORINDIFOLIA. THE LETTUCE TREE.

Lutchee-kottay-ellay, TAM.

The leaves of this pretty tree are used in various ways; sometimes by Europeans; they make tolerable greens cooked with cocoanut, chillies, &c., &c., to be found only in gardens, leaves of a light green colour, turning nearly white during the hot months.—*Jaffrey.*

(6378) PISTACIA, a genus of Plants belonging to the natural order *Anacardiaceæ*. It has diœcious, apetalous flowers. The male flowers with the raceme amentaceous, with 1-flowered bracts; calyx 5-cleft; stamens 5; anthers subsessile, 4-cornered. Female flowers with the raceme more lax; calyx 3-4-cleft; ovary 1-3-celled; stigmas 3, rather thick. Drupe dry, ovate, with a somewhat bony nut, usually 1-seeded and 1-celled. Seeds solitary, each without albumen. *Eng. Cyc.*

(6379) PISTACIA LENTISCUS. MASTIC TREE. A Native of the South of Europe and of Asia Minor, introduced into the Calcutta Garden in 806. The bud, bark, leaves, and fruit have all been used in medicine, but have been laid aside in modern times.—*Roxburgh.* The bush is found on the coasts of the Mediteranean. The leaves are evergreen, equally pinnate; leaflets 8 to 12, usually alternate, with the exception of the two upper, which are opposite, oval, lanceolate, obtuse, often mucronate, entire, and perfectly smooth. Flowers very small, in axillary panicles, similar to those of the other species; fruits very small, pea-shaped, reddish when ripe. The sweet fragrant stimulant resin called *Mastich* is obtained from the trunk by incisions made in the month of August. It is used to strengthen and preserve the teeth and in diarrhœa.

(6380) *Mastic Resin*, Roomie Mastike, or Turkish olibanum, Manna of Lebanon.

Sakes, ARAB. | Kunnoli, TUR.
Koondar Roonee, PERS. | Ulmastiga, SP.

This valuable substance occurs in oval tears of variable size, smooth, diaphanous, brittle, breaking with plane brilliant, glassy, and pale yellow surface, and owing to its brittleness being usually covered with its own dust. Its odour is agreeable; flavour weakly balsamic; it softens in the mouth, and becomes ductile like white wax. It melts at a moderate heat, and then exhales a sweet odour. Mastic is quite insoluble in water, it yields to alcohol 80 per 100 of soluble matter, leaving a substance resembling caoutchouc, which is slowly dissolved by ether. This resin gives its name to the process of *mastication*, being universally chewed in the East; it is much used by dentists for filling up carious teeth; it is burned as incense; and in some parts of Greece it is added to bread in small quantities to give it an agreable flavour. Mastic is extensively employed as a transparent varnish, dissolved in turpentine or alcohol, with other resinous bodies. A species of mastic called *tum* is obtained in Africa from the Pistacia Atalantica. The true resin is sold in all the Bazars for about three rupees the seer.—*O'Shaughnessy, p.* 278.

(6381) PISTACIA TEREBINTHUS. Pist. vera. Terebinthus vulgaris.

Katinge Roomie, ARAB. | Butum, ARAB.
Zangbarie, PERSIAN. | Sukhur, PERS. (Royle).

A native of Barbary, Greece, and the South of France. A resinous juice of much value is afforded by this tree.—*O'Shaughnessy, p.* 276.

(6382) PISTACIA VERA, is a small tree, or large bush, from 15 to 20 feet high; its leaves are alternate, unequally pinnated, without stipules, and consist of from 3 to 5 oval blunt leathery smooth leaflets. The flowers are small, and arranged in short branched racemes from the old wood; some are male and others female; the latter are succeeded by dry drupes about the size of an olive, of a reddish colour, with a very thin rind, a brittle 2-valved shell, and contain a single almond-like seed with a green embryo. The tree is originally from Asia Minor, but is now naturalised all over the South of Europe, where the fruit is in request for confectionary and for the dessert, under the name of Pistachio Nuts. —*Eng. Cyc.* According to Mr. Elphinstone it grows wild in the Hindu-kosh. The almond and pericarp are imported into India from Cabul, with a kind of gall termed *Gool-i-pista* and a resin called *Alook-ul-imbat*. *Royle's Illustra.*, p. 178.—*O'Shaughnessy, p.* 277.

(6383) PISTACHIO NUTS.

Pistaches, DUT. | Pistacchi, IT.
Pistaches, FR. | Pistacias, LAT.
Pistaschen, GER. | Alfocigos, SP.
Pistach, GUZ. & HIND.

The produce of *Pistachia vera*, which grows

abundantly in Arabia, Persia, Syria, and Sicily. They are oblong and pointed, about the size of a filbert, inclosing a kernel of a pale greenish colour, covered with a yellowish or reddish skin. They have a pleasant, sweetish, unctuous taste, and are chiefly served up at the dessert. Pistachio nuts are imported into Bombay from the Persian Gulf.—*Faulkner.*

(6384) PISTIACEÆ, *Lemnads*, or DUCK Weeds, a natural order of Endogenous Plants. The species are floating or land plants with very cellular, lenticular, or lobed fronds or leaves, some of them wholly destitute of spiral vessels, except perhaps in the pistil. The flowers appearing from the margin of the fronds 2 or 3, naked, inclosed in a spathe, but without a spadix. In the male flowers the stamens are definite, often monadelphous: in the female flowers the ovary is 1-celled, with one or more erect ovules; style short, stigma simple, ovules anatropal, hemianatropal, or atropal. Fruit membranous or capsular, not opening, one or more seeded; seeds with a fungous testa and a thickened indurated foramen; embryo either in the axis of fleshy albumen and having a lateral cleft for the emission of the plumule, or at the apex of the nucleus, covered in by a hardened endostome. The common Duck-Weed *Lemna* may be regarded as the most simple of all Phænogamous Plants. It inhabits the ditches of the cooler parts of the world. [LEMNA.] *Pistia* is found in the tropics; *Ambrosinia* in the basin of the Mediterranean.—*Eng. Cyc.*

(6385) PISUM, a genus of Plants belonging to the natural order *Leguminosæ*, and the tribe *Viciceæ*. It has a calyx with foliaceous segments, the two upper ones being shortest; the vexillum ample, reflexed; the style compressed, carinated, villous above; the legume oblong, rather compressed, but not winged; the seeds globose, numerous, with a roundish hilum.—*Eng. Cyc.*

(6386) PISUM ARVENSE has 1-flowered peduncles and always red flowers, and yields the gray peas of the fields.—*Eng. Cyc.*

(6387) PISUM SATIVUM. PEASE. Lin.

Puttanee, TAM.	Herenso. SANS.
Patana, GUZ.	Butanee, HIND.
Buttaneh, DUK.	Common Pea. ENG.
Gooadoo sanigheloo TEL.	*Ainslie, p.* 244.

Pisum Sativum has two or many-flowered peduncles, with red or white flowers and is the common pea of our fields and gardens.—*Eng. Cyc.* These are indigenous to the Mahratta countries. The native country pea is sown after the rains in drills, and varies in price according to the quality; when green, they are tolerable as a vegetable, but are best in soup. Procurable in December and January.—*Riddell.*

(6388) PITA OR AGAVE, commonly called Aloe (*Agaveæ*, a tribe of *Amaryllideæ*).

Cantala and Bans-keora. HINDEE.	Petha-kalabuntha. TAMUL.

The species of Agave, commonly called aloe plants, are natives of America, which have become so naturalised in many parts as to appear to be indigenous in Africa, parts of India, and in the south of Spain. So much is the latter the case, that some authors take this American plant to be the aloe wood mentioned in Scripture. But there is not the slightest foundation for this opinion, nor indeed for the true aloe plants, of which the agaves so frequently assume the name. The Aloes wood of Scripture is the *Ahila* wood of the East, so famed for its fragrance, yielded by *Aquilaria Agallochum*, &., (*v. Ahalim* by Dr. Royle, in Kitto's, 'Cycl. of Biblical Literature,' i, p. 90.)] But, as they also yield some fibre, it is better to retain for them their appropriate name of Aloe. The Agave plants, to which the name of American aloes is so frequently applied, resemble the true aloes in their sword-shaped leaves with parallel veins, which, however, grow to a gigantic size—that is, from eight to ten feet in length—in a cluster from the root, with their margins usually armed with short thorns, and their points with a hard and sharp thorn. This makes these plants so useful in the construction of hedges; a use to which they are applied in the south of Spain and of Italy, as also in Sicily. These plants come to perfection in about three years, though they do not flower for eight, and, in some situations, perhaps not for twenty years, when they throw up a tall candelabra-like flower stalk. This has, no doubt, given origin to the fable of their flowering only once in a hundred years. It is the leaves of these plants which abound in fibres of great length, and of considerable strength. Being also tough and durable, they are separated for the purpose of making string and rope, not only in their native countries, but also in those into which they have been introduced. Dr. Royle, in his 'Illustrations of Himalayan Botany' (p. 375), observed, respecting these plants: "The species of agave are not only ornamental as plants, and useful as hedges, but are important for their products. The roots, as well as leaves, contain ligneous fibre (*pita thread*) useful for various purposes: these are separated by bruising in water, and afterwards beating; practices which the natives of India have adopted, either from instruction or original observation. The Mexicans also made their paper of the fibres of agave leaves laid in layers. The expressed juice of the leaves evaporated, is stated by Long, in his 'History of Jamaica,' to be also useful as a substitute for soap. But the most important product of agave, and especially *A. americana*, the species now most common in the South of Europe, is

PITA OR AGAVE.

the sap, which exudes upon the cutting out of the inner leaves, just before the flower scape is ready to burst forth; of this a very full account is given by the illustrious Humboldt, in his 'Political History of New Spain' (book iv, c. 9). The fibres of these Agave leaves are, in Mexico, converted into twine, cord, or rope; the last used in mines, and on the western coast, towards Guayaquill, for the rigging of ships. Humboldt describes a bridge over the River Chambo, in Quito, 131 feet in span, of which the main ropes, four inches in diameter, were made of the agave; and upon these ropes the road-way was placed. In the West Indies, the negroes are described as making ropes, fishing-nets, and hammocks of agave fibres. The fibre is thus prepared: the longest and most perfect leaves being cut off, are laid upon a board and scraped with a square iron bar, which is held in both hands, until all the juice and pulp are pressed out, the fibres only remaining. Stedman says, the fibre is like white silk, and hence it obtains the name of silk-grass; though this seems to be also applied to the fine fibres of *Agave vivipara*, and of *A. yuccæfolia*. But others of these white endogenous fibres are better entitled to the name, as they are softer and more flexible. Stedman says, ropes made of this material are stronger than any in use in England; but that they are liable to be sooner damaged by immersion in water. In Portugal the fibre is called *filo de pita*, and applied to various purposes. In Spain also, the fibre is called Pita, and used for making string and rope, the plant being abundant in the southern provinces. In Sicily, the fibre is said, by Dr Balfour, to be called Zambaroue, where cordage and mats are made of it. Pita fibre is extensively used in South America for even considerably sized rope.

Pita fibre and rope have been stated to be prepared from the Agave so common in the south of Spain, though not to the extent at which the manufactory might easily be carried on. M. Romon de la Sagra recommends the introduction of other kinds from Guatimala and Columbia, which are known there by the names of "Cabulla" and "Cocaiza." Species of Fourcroya also yield excellent fibre. *F. gigantea* is common at St. Helena and has been introduced into Madras. Pita fibre was sent to the Exhibition of 1851 from the island of Madeira, and also from Barbadoes and Demerara. Thread and paper made from *Agave americana* were also sent from Mexico, and fibre is also said to be obtained here from a species called "*Moogai*"—*Agave tiacantha* by botanists.

The name Pita seems to be also applied to similar fibres obtained from species of Bromelia and of Yucca, as well as of Agave, according to Dr. Hamilton, of Plymouth and it is probable that it is so, for these are all very similar to each other. Dr. Hamilton further states, that the weight of Pita fibre being one sixth less than that of hemp, the difference would be very considerable for the entire rigging of a ship and produce a sensible reduction in the top weight, and thus increase the stability of the hull. He considers it also more durable than hemp, and that it bears the alternate action of humidity and of dryness with little injury; hence it is preferred for cables, standing rigging of vessels, nets for fishing, &c. The difference in hygrometric action is also in favour of the Pita. In a few months' trial in H M.S. Portland, a log-line, 300 feet long, of Pita, contracted sixteen feet two tenths, whilst a similar one made of hemp contracted twenty-one feet six tenths; the contraction, moreover, of the Pita ceased the third day, while that of hempen cord continued the whole time. The two lines have been deposited in the stores of the dockyard at Plymouth. At Amboyna, says Labillardiere, the natives produce threads from the bastard Aloe, called *Agave vivipara*: the master of the house went and cut a leaf off this plant, and, resting it on his thigh, in order to scrape it with his large knife, he took off its pulp, and obtained from it a fascicle of threads as long as the leaf, and as strong as those of our best hemp. The Agave grows well on the north coast of Africa, and its fibre has been paid much attention to by the French since their occupation of Algeria. There, it is stated, when fodder is scarce, cattle will eat the younger leaves when cut into transverse slices. A clock and paper made of this fibre were sent to the Exhibition of 1851; and ropes have been made of the fibres—of these the strength is very considerable. The Agave or Pita fibre being so extensively employed in different parts of the world, there is no doubt that it would be a valuable culture for many parts of India. It was probably introduced into India by the Portuguese, and is now common in both the northern and southern parts of India. The species which D. Royle found most common in the north-west of India was *Agave vivipara*. This seems to be the same as the *Agave americana* of Roxburgh ('Herb Amb.,' v, 94). He observed that on rich soils, the plant invariably produced bulbs, but no seeds, while on a poor stony soil and dry climate, like that of Delhi, seeds alone are produced. This species must be closely allied to the *A. cantala* of Dr. Roxburgh, which is, no doubt, a naturalised plant. These species or varieties flourish in dry parts of the country, where few fibre-yielding plants succeed so well, such as in the Deccan and in Mysore. For in the north-west, the outer hedge of the Saharunpore Botanic Garden was formed of the Agave, and the fibres were commonly used for all garden purposes. Dr. Buchanan, at the beginning of the century, found the villagers in Mysore employing it for

making strong hedges, and separating the fibres for cordage; and Mr. Webb, who was employed with Dr. Anderson in cultivating the Nopal for the Cochineal insect, had a plantation of the Agave, near Madras. Of this the fibres were made into rope, and reported upon at the arsenal of Fort. St. George, as long since as the year 1798. Mr. William Webb having made a plantation of the Agave plant, in the year 1798 manufactured ropes from its fibres, which he considered superior in a strength to that made in Europe. He also stated that he believed rope without tar to be preferable for all military purposes. He submitted a coil of this rope to the Military Board of Fort St. George, with a suggestion that he should be allowed to supply it in lieu of rope made in Europe. Capt. P. Malcolm, of H. M. S. Suffolk, writing from Cochin, reported upon it, "as strong, if not more so, than Coir, and as having the advantage in pliability." A Committee of the Military Board were "of opinion, that its appearance promises well, and that from a trial that has been made of it, it is at least equal when new to the best Europe rope of the same size in point of strength. Sixteen of the battering guns having been mounted with it before it gave way, while Europe rope of a larger kind failed after it had been employed in mounting only four guns." But it was observed that the yarns were made too large, and that diminishing their size would augment their strength. With respect to its durability, the Committee had no experience, but report that a coil which Mr. Webb stated "had been fixed to the anchor of his boat at Ennore, and kept constantly under water for six months, appear to have undergone no other alteration than Europe rope would have done in the same situation." In another report made by the Commissary of Stores, Fort St. George, dated 27th July, 1801, on a coil of Aloe rope manufactured at Seringaptam, it is stated that "the coil of Aloe rope was, on its being received at the Arsenal, the 10th of June, immersed in a tub of water for twenty-four hours, and then exposed to the open air in the yard; since which date, a few showers of rain have fallen, after each of which the coil was turned; and upon being examined and tried the 27th instant, it was found to be quite rotten." From this it was inferred that Aloe rope will not stand wet; and it was stated that this was also the result of similar rope supplied to H. M.'s squadron then in India. ('Madras Artillery Records' for 1839.) Though nothing is so objectionable in a rope for naval purposes as inability to bear exposure to wet, the above experiments are inconclusive, because we are without any information respecting the species of Agave which was cultivated, and also respecting the soil and climate where it was grown, as well as the time which the fibre was macerated before it was separated. All which influence not only the strength of fibre, but its capability of bearing moisture. The result of the experience in India is moreover, contrary to that of South America. The employment of the fibres of this plant seems very general, as it has since become widely distributed through the Madras Presidency. Thus it is so employed at Masulipatam and at Bellary. At Cuddapah, the natives make ropes of it thirty cubits in length. The plant is abundant about Madura, whence fibre and cordage were sent. The fibres are prepared by pressing the leaves between two horns and then washing the pulp away. The ropes are described as being manufactured in great abundance, and at trifling expense; and that they are much used for lashing bales of calico. The fibres are also separated on the Malabar coast, and specimens were sent from the prisoners in the jail. But the most varied assortment of specimens was sent from Madras, prepared at the instigation of Dr. Hunter in his School of Arts, and by the prisoners in the Jails at Madras. Of these, the Agave was in the state both of fibre and of oakum; also made into string, cord, and rope, and dyed orange, red, maroon, and green, showing how well this fibre takes these colours. Also, some good paper, made with this fibre, mixed with that of gunny bags. In Madras, this plant is called *petha kalabuntha*. The usual way of preparing these fibres is to steep them in water for three days, and then to clear away the herbaceous part. But the best way of steeping is that practised by the natives in some places; that is, of baking the leaves in wet sand. But the fibres may also be separated by first beating, and then scraping away the rest of the vegetable tissue. The beating is required on account of the hardness of these succulent leaves. Pressing them through grooved cylinders, would, no doubt, be efficacious and also expeditious. The Agave is also common in the Bengal Presidency, where it is called *pantala*; and also *bans keora*, or "Bamboo Pandanus." Though, probably most valuable in the upper provinces, yet, in December, 1839, Mr. Bond, master-attendant at Balasore, sent to the Agricultural Society of Calcutta, a piece of cloth manufactured by him from a species of the Aloe plant, of which he sent a leaf; and stated that the cloth had been woven without the thread having been spun. As already mentioned the fibre was constantly employed for garden purposes at Saharunpore. Mr. Tonnochy, B. C. S., succeeded in spreading the culture in the Boolundshuhur district, by exposing, in his office, some of the dressed fibre, and also a couple of sattranjees or carpets made of them, together with heaps of seed. These all disappeared. Mr. Tonnochy encouraged the culture as a hedge plant, because it was not only valuable on its own account, but also, because enclosing the fields so much enhances the value

of land. The long, flowering stem was, moreover, found useful as a ridge-pole for cottages. In the year 1852, Sir R. C. Hamilton, resident at Indore, forwarded some specimens of the fibre of the *Agave Cantala* which grows freely in Malwa, and to which attention had been directed during the temporary want of "Bakkul," the fibrous bark of the roots of certain trees, which is used in that part of India as a cheap substitute for string and cord. Dr. Tranter found he could pull out single fibres, measuring from twenty to thirty inches in length; but he separated a larger quantity by macerating the leaves in water for a week and then beating them with a stick. Capt. A. Thompson, of Messrs. T.'s rope-manufactory at Calcutta, having tested the fibres, found the strength quite equal to the best Russian hemp. He also states, in June, 1852, that a considerable quantity of fibre, exactly similar, had lately been imported from the Malabar coast, and that he had some made into rope, which very much resembled Manilla rope: but time was required to test its durability. It was then worth about four rupees per bazar maund in the Calcutta market. Though this Pita or Agave fibre is so much employed in different parts of the world, its great merits seem to be, generally, but little known. We have seen that in South America, ropes made with it are considered both strong and durable. The ropes made at Algiers have been found to possess great strength; and the log-lines in H. M. ship Portland to be both durable and not shrinking after the third day. In lightness and colour they resemble ropes of Manilla hemp, though they are not usually so strong. But in a "comparative trial made at Paris, between ropes made of hemp and of the aloe from Algiers, the latter was found to bear 2,000 kilogrames, while the former, of equal size, bore only 400." So, in some comparative trials made at the French dock yard at Toulon, on ropes made from these fibres and from hemp, the following results were obtained, both being immersed in the sea for six months, and exposed to the atmosphere for the same time.

PITA.	Weight supported.	HEMP.	Weight supported.	Difference in favour of Pita
	Pounds.		Pounds.	Pounds.
Plunged in sea, ...	3,810	Plunged in sea, ...	2,538	1,272
Exposed to air, ...	3,724	Exposed to air, ...	3,022	702

In the year 1841 some rope was made under the direction of Mr. Hornby at the Allipore Jail rope-walk, of Aloe, or rather Agave fibre, obtained from plants which had been grown by the convalescent insane, near Calcutta. Mr. Hornby tested this rope against others made of Country Hemp (that is *Sunn*), Jute, and Coir, and he found the Agave rope exceed the others

in strength, as appears from the following statement sent by him to the Agricultural Society of India:

CALCULATION OF THE POWERS OF ALOE FIBRE ROPE, COUNTRY HEMP, JUTE, AND COIR ROPE, TRIED AT THE ALLIPORE JAIL ROPE-WALK.

			lb. Troy.
Aloe Fibre Rope, 1 fathom long, and 3 inches in circumference, broke in a weight of...	...	...	2510½
Coir	do.	do.	do. 2175
Country Hemp	do	do.	do. 2269½
Jute	do.	do.	do. 2456½

In some experiments made by Dr. Royle, he found a bundle of the fibres bore 270 lb., while a similar bundle of Russian hemp bore only 160 lb. Dr. Wight had some cord prepared with the Agave fibre in Coimbatore, and found it bore 362 lb.; when similar rope, made from Crotolaria juncea broke with 407 lb. The following are the results of—

EXPERIMENTS MADE IN THE ARSENAL AT FORT ST. GEORGE, JULY 30TH, 1850, ON ROPES MADE IN JAIL AT MADRAS, IN 1850. For similar experiments on rope, &c., made from plantain fibres, see FIBRES.

	Circumference.	Length.	Weight required to break.	After 24 hours in water, and used 7 days after.	Immersed in water 10 days and dried.	Manilla Rope.	English Hempen Rope.	Weight of one fathom of each. Pita.	Manilla.	Europe.

Cord, ...	0 3/16	1	39½	34½	37 14/16	—	—	0 2/16	—	—

These experiments prove incontestibly, that the Pita fibre is possessed of very useful properties; and we have seen that the Agave plant has become naturalised in many widely separated parts of the Indian territories. Its characteristics have been dwelt upon in detail, because it seems calculated to prove extremely useful in India.

First, because it grows in dry climates and poor soils, such as may be met with both in the Deccan and in Mysore. It will, in such situations form a very effective hedge—useful, not only in keeping off from the crops the innumerable herds of deer, &c, but also in assisting in saving the soil, a road or a railway, from being covered with the sand blown from the desert. The leaves would form a continual source of employment for the people, in separating an abundant supply of material for cordage. This will, at all events, be sufficiently good for all agricultural purposes, for the harnessing of cattle, the baling of produce, and for the rigging of vessels employed in river navigation. The fibre is also sufficiently good to form an exportable article of considerable value, especially as the prejudice against white cordage will by degrees be removed, and the two will be invaluable for the manufacture of paper. It is desirable that some comparative experiments should be made on the age at which the leaves should be collected, and on how long they should be steeped. Also, whether this process is necessary at all; that is, whether the fibre may not be separated by mechanical means. The climate best suited to the growth of the strongest fibre should be ascertained, as well as what are the differences of quality between the fibre of different species of Agave. Also, the susceptibility of different kinds to the effects of moisture, either with or without superficial tarring. In the preparation of the cordage submitted to trial, care should be taken that the fibres are so prepared as to cut each other as little as possible when tested; and also that the cordage is made by a regular rope-maker.—*Royle, Fib. Pl. p.* 4.

(6389) PITCH.

Poix, Fr.	Pece, It.
Pech, Ger.	Smola-gustaja Rus.
Pitch, Guz. & Hind.	Pez, Sp.

The residuum which remains on inspissating tar, or boiling it down to dryness. It is extensively used in ship-building, and for many other purposes.—*McCulloch. Faulkner.*

(6390) PITCH BLENDE. A ponderous metalliferous ore, of a blackish colour, much valued by porcelain painters. Localities, Saxony, Bohemia, Hungary, and Cornwall.—*Waterston. Faulkner.*

(6391) PITH MODELS. The Trichinopoly Local Committee exhibited a large collection of figures and architectural models, carved in the Pith of the Typha. The attitudes of the figures are stiff but the draperies are characteristic. The figures introduced into the model of the Trichinopoly Fort are out of proportion being far too large for the scale of the buildings.

Pith Models of Pagodas..... { Trichinopoly and Salem.

Pith work made from the rushes called "Nultee"..... { Tanjore.

Model of the Pagoda.

(6392) PITTA, M. Vieillot's name for a genus of remarkable birds, placed by Mr. Swainson among the *Myiotherinæ*, or Ant-Thrushes. [Muscicapidæ.] *Eng. Cyc.*

Pitta (Vieill., Temm.).—M. Lesson remarks that, under the name of *Myiothera*, Illiger and Cuvier united the Brèves of Buffon and the Ant-Thrushes properly so called. These Brèves are remarkable, he observes, for the livid colours of their plumage, their long legs, and their very short tail. They are only found, he adds, in the Malaisian Islands, whilst the Ant-Thrushes belong to the New Continent as well as to the Old World. Mr. Swainson notices the genus *Pitta* as one of remarkable beauty, and observes that they have the gradually-curved bill of the true Thrushes, but much stronger.—*Eng. Cyc.*

(6393) PITTA GIGAS, Brève Geant, or Giant Pitta. Size equal to that of a magpie, but the tail is short and squared, and the wings cover it entirely. A very brilliant azure-blue covers the back, the scapulars, the rump, and tail; a less vivid tint is spread over the wings, the quills of which are black, covered with azure towards the tips; summit of the head, nape, and demi-collar of the lower part of the neck black; feathers of the front and eye-brows ashy-brown; throat whitish; an ashy-brown tint is spread over all the lower parts; the feet are very long and of a horny-ash colour. Total length 9 inches. It is found in Sumatra. (Temminck.) —*Eng. Cyc.*

Cidaris ma thalassinum (*Kitta thalassina, Pitta Thalasin*, Temm.). Greater part of the plumage very brilliant celadon-green; a velvety black band springs at the angle of the bill, passes backwards so as to include the eye, and surrounds the occiput; tail deep tarnished green; wings reddish, but the three or four secondary feathers nearest the body are opaline bluish-ash; iris, bill, and feet, very bright vermilion-red. Total length 11 inches 2 or 3 lines. The male and female have nearly the same livery. The young of the year differ in the colour of their bill and feet, which are black; in that of the wings, which is a tarnished rusty-red, and in the very clear blue, which is nearly whitish, of all the rest of the plumage. This blue tint is more vivid in middle age, and passes by degrees from bright azure-blue to celadon-green. Individuals during moult have the plumage varied with these two tints very vivid and pure. It is a native of Java and Sumatra. (Temminck.)—*Eng. Cyc.*

(6394) PLANKS.

Planker, Dan.	Takhta, Guz. Hind.
Planken, Dut.	Tolstale doski, Rus.
Planches, Fr.	Plankor, Sw.
Planken, Ger.	

A term applied to thick, strong, boards, cut from various kinds of wood.—*Faulkner.*

(6395) PLANTAGO, a genus of Plants, the type of the natural order *Plantaginaceæ*. It has a 4-cleft calyx, a corolla with an ovate tube, and a 4-parted reflexed limb. The capsules burst transversely; they are 2-4 celled, and have from 2 to 4 seeds. The seeds of *P. Ispaghula* are of a very cooling nature, and with boiling water form a rich mucilage, which is much used in India in catarrh, gonorrhœa, and nephritic affections. Soda is obtained in Egypt from the ashes of *P. squarrosa*.—*Eng. Cyc.*

(6396) PLANTAGO ISPAGHULA.

Ispagool, Pers.	Fuslioon, Greek.
Buzr-kaloona, Arab.	

In India the Plantago Ispaghula is cultivated during the cold season for the seeds, which are used as an emollient and light article of diet for convalescents.—*O'Shaughnessy, page* 510. In making a decoction of Ispaghool take of Ispaghool seeds two drachms, distilled water one pint. Boil and strain. This preparation is a simple demulcent. That of Isphaghool is used in dysenteries, and recommended by Mr. Twining. —*Bengal. Phar. p.* 277.

(6397) PLANTAINS, Banana.

Biyu, Bali.	Kudali, Sans,

It is probable that the plantain and the banana are merely varieties, indeed that all the plantains are derivable from one species, the Musa sapientum, also called M. paradisiaca, the original of which is the wild Musa. The Musa is found in all tropical countries, and in India the common edible varieties flourish in the poorest of soils, from the most northern parts of India to Cape Comorin, and from the sea shore to elevations of 7000 feet. M. Coccinea M. Cavendishii are found in China. M. Glauca is indigenous in the Malayan Peninsula. M. Ornata in Chittagong. M. Superba is found in the valleys of the south of the Peninsula, and of the mountains at Dindigal. The varieties cultivated in Southern India, *Rustaley, Poovaley, Payvalley, Monden, Shevalley, and Putchey valley*, are to be found in most bazars. The plantain is one of the most useful of plants; in some countries supplies the place of bread and forms the chief nutriment of the people; its ripe fruit is eaten everywhere in India as a delicacy, and is also made into preserves. The farinaceous parts can be separated in the form of flour. The shoots or tops of young plants are given as fodder for sheep and cattle and are said to be a delicate edible. The leaves serve for thatch and bedding and the stem yields valuable fibres. Humboldt has calculated that the same amount of ground planted with the Banana will support a far greater number of people than when planted with wheat, but the productiveness according to the following statements differs with the mean temperature. Professor Johnston being the authority for the yield of dry food.

	Temperature.	Produce of Plantains per Imperial acre.	Or of Dry Food per acre.	
	Fah.	tons.	tons.	
In Warm Regions,	81½	72	19½	Humboldt.
At Cacua,.....	78⅘	59	16	Gondot.
At Hague, ...	71⅔	25	6¾	Boussingault.

In South America, Mexico and in Bombay, the fruit cut into slices and dried in the sun, and packed in the leaves of the plant forms an article of trade; they can also be baked, and in this state the sugar on the fruit is sufficient to preserve them for years; in the process of drying, the plantain is taken when fully ripe and laid in light cane frames exposed to the sun. When shrivelling commences the skin is peeled off, after which the drying process is completed, and the fruit is pressed with masses for the convenience of transport; in the moist climates of India it would be necessary to bake them in ovens. In 1850-51, 267 cwt., valued at Rs. 1456, were exported from Bombay to Cutch and Guzerat. The several varieties of the edible plantain which are known and cultivated throughout the West Indies, Africa, and in the East, are all reducible to two classes, viz., the Plantain and the Banana (*Musa Paradisiaca* and *sapientum*). The difference between these two plants is even so slight as to be scarcely specific; it is therefore most probable that there was originally but one stock, from which they have, by cultivation and change of locality, been derived. The plantain and its varieties invariably bear male, female and hermaphrodite flowers within the same spathe, all of them being imperfect and consequently unproductive of seed. An individual may, even from excess of culture, moisture, &c., be entirely incapable of flowering. During the prevalence of a disease or blight among the plantain walks of Demerara in the years 1844 and 1855, it was seriously proposed to introduce male plantains, or obtain fresh stock by seed. It was therefore necessary to determine with exactness if possible, whether the Plantain or Banana, (whichever be the parent stock) exists anywhere at present, or has been known to have existed as a perfect plant, that is bearing fertile seeds; or, whether

it has always existed in the imperfect state, that is, incapable of being procreated by seed, the only state in which it at present exists in our colonies. Linnæus conjectured (Spec. Plant, 1763) that the "Bihai" (*Heliconia humilis*), a native of Caracas, which produces fertile seeds, was the stock plant of the plantain; but the existence of a wild seed-bearing plantain, renders it unnecessary to pursue that speculation. The banana, from time immemorial, has been the food of the philosophers and sages of the East, and almost all travellers throughout the tropics have described these plants exactly as they are known to us, either as sweet fruit eaten raw, or a farinaceous vegetable roasted or boiled. The foliage of the plantain affords food and bedding, and is used for thatch, making paper, and basket making; and from its petioles is obtained a fine and durable thread. The tops of the young plants are eaten as a delicate vegetable; the fermented juice of the trunk produces an agreeable wine. The abundance and excellence of the nutritive food which the plants of this valuable genus supply are well known; but of the numerous uses to which they are applied I may mention the following:—The fruit is served up both raw and stewed; slices fried are also considered a delicacy. Plantains are sometimes boiled and eaten with salt meat, and pounded and made into puddings, and used in various other ways. In their ripe state these fruits contain much starchy matter. From their spurious stems, the fibres of the spiral vessels may be pulled out in such quantity as to be used for tinder. *M. textilis* yelds a fibre which is used in the manufacture of fine muslins, and the coarser woody tissue is exported in large quantities from Manila, under the name white rope or Manila hemp. Horses, cattle, swine, and other domestic animals are fed upon the fruit, leaves, and succulent trunks. The same extent of ground which in wheat would only maintain two persons, will under the banana yield sustenance to fifty. That eminent naturalist and elegant writer, the Baron Von Humboldt, states ("Political Essay on New Spain," vol. ii.) that an acre of land cultivated with plantains produces nearly twenty times as much food as the like space sown with corn in Europe. He refers to a place in Venezuela, where the most careful tillage was rendered to a piece of land, yielding produce supporting a humble population residing in huts, each placed in the centre of an enclosure, growing the sugar cane, Indian corn, the Papaw tree, and the Musa—a tropical garden!—upon the elaborate culture of which a whole family relied for subsistence. Lindley enumerates ten species of Musa, some of which grow to the height of 25 or 30 feet, but the valuable species *M. Cavendishii*, does not grow more than four or five feet high. The bananas of the family of the Musaceæ, appear to be natives of the southern portion

of the Asiatic continent (R. Brown, "Bot. of Congo," p. 51). Transplanted at an unknown epoch into the Indian Archipelago and Africa, they have spread also into the New World, and in general into all intertropical countries, sometimes before the arrival of Europeans. According to Humboldt it affords, in a given extent of ground, forty-four times more nutritive matter than the potato, and 133 times more than wheat. These figures must be considered as only approximative, since nothing is more difficult than to estimate the nutritive qualities of different aliments. The plantain may be deemed the most valuable of fruits, since it will, in some measure, supply the place of grain in time of scarcity. To the negroes in the West India Islands the plantain is invaluable, and, like bread to the Europeans, is with them denominated the staff of life. In Jamaica, Demerara, Trinidad, and other principal colonies, many thousand acres are planted with these trees. The vegetation of this tree is so rapid that if a line of thread be drawn across, and on a level with the top of one of the leaves, when it begins to expand, it will be seen, in the course of an hour, to have grown nearly an inch. The fruit when ripe is of a pale yellow, about a foot in length and two inches thick, and is produced in bunches so large as each to weigh 40 lbs. and upwards. In the Straits' settlements of the East, the following are the most approved varieties:—The royal plantain, which fruits in eight months; one which bears in a year, the milk plantain, the downy plantain, and the golden plantain or banana. A species termed *Guindy* has been lately imported from Madras, where it is in great request. It has this advantage over the other kinds, that it can be stewed down like an apple while they remain tough. The Malays allege that they can produce new varieties, by planting three shoots of different sorts together, and by cutting the shoots down to the ground three successive times, when they have reached the height of nine or ten inches. In some districts of Mexico it is, indeed, dried in the sun, and in this state forms a considerable article of internal commerce under the name of "plantado pasado." When dried, and reduced to the state of meal, it cannot, like wheat flour, be manufactured into maccaroni or vermicelli, or at least the maccaroni made from it falls to powder when put into hot water. The fresh plantain, however, when boiled whole, forms a pretty dense firm mass, of greater consistency and toughness than the potato. The mass, beaten in a mortar, constitutes the *foo-foo* of the negroes. The plantain meal cannot be got into this state unless by mixing it up with water to form a stiff dough, and then boiling it in shapes or bound in cloths. The advantages to the paper manufacturers in employing the prepared fibre instead of rags, will be numerous, for the fibre is equal in texture,

clean, and aromatic; whilst rags are dirty, full of vermin, and very often pestilential. A large stock of the plantain can always be secured, without fear of its being injured by keeping. The paper will be superior to that made of rags, and the process of making it will be more economical, inasmuch as the *sorting* of the material will not be required. Another advantage is, that a new article of commerce will be opened for the benefit of the colonial shipping interests and a stimulus will be given to the cultivation of a fruit which is the favorite food of large masses of the population. The following is a "specification" of articles requisite for making three tons of prepared fibre in a day:—Four wooden boilers lined with lead, in the form of coolers, 7 feet deep by 6 in diameter. One hydraulic press, from 400 to 500 tons. One stout screw press, to compress the fibre before it is submitted to the hydraulic press. One iron mill with horizontal cylinders. Six waggons; twenty mules. Utensils, such as spatulas, cutlasses, hoes, rakes, &c. &c. One lever, to take out the fibre from the boilers. One steam boiler, equal to 12-horse power, to steam the four wooden boilers. It being very desirable that the works should be in the immediate neighbourhood of a river, the machinery should be worked by water-power; but if this mode should be inconvenient, a steam engine in addition must be obtained, of about 8 or 10-horse power; or if one steam engine of 20-horse power were employed, it would be sufficient for all purposes. Thirty men are required to make three tons of fibre in a day.—*Simmonds.* Although perhaps there is no province in India in which plantains are grown to so great an extent as in Pegu, yet there are scarcely any good plantains to be had in the country. This is owing to the Burmese habit of only eating green fruit, and their total indifference to the finer qualities of flavor. The great use of all fruit with the Burmese is to serve as an addition to their curry, for which purpose one kind of plantain is just as good as another. But now that a market is opened for the better description of this and other kinds of fruit, the introduction of a good stock becomes desirable.—*McClelland.* The plantain or banana, though a far less palatable fruit, holds the same place in Tenasserim that the apple does in England, and the United States. It is used as a vegetable as well as an article for the dessert, the great proportion being eaten with rice and meat in the place of potatoes. There is perhaps no plant of which so many preposterous things have been carelessly written in books of travels, and then copied into works of graver character, than this. Among other things equally veritable, it is said, "Three dozen plantains are sufficient to serve one man for a week instead of bread, and will support him much better." A Karen by me says he often eats ten at a time, and a hundred would not be sufficient for a man one day if he had nothing else, unless they were very large. Like the mango, the tree is indigenous, but the wild fruit is too full of seeds to be eatable. The plantain and banana, which were formerly regarded as distinct, are now considered by botanists as one species, but it embraces many varieties; I have, says Mr. Mason, the Burman names of *twenty-five* before me. "The numerous varieties," writes Voigt, "we have in vain tried to put in some order. The attempt made for this purpose, in Schultens, appears to us to have only increased the confusion." The *Manila hemp*, from which a fabric of the finest texture is prepared, is made from the leaves of a species of plantain tree, *M. textilis.* Another distinct species of this genus grows wild in Tenasserim jungles, and is rather an ornamental plant, which is all that it has to recommend it. Unlike the common plantain it never throws up shoots from its roots. The name of the plantain in Pali is *manza*, which is its Arabic name, *mauz*, with a final vowel added, to pronounce the last consonant, no words in Pali, ending in any consonant excepting *n*. Now if its Arabic name be so widely diffused, it seems quite certain that had the plant been known to the Hebrews, the Hebrew being cognate with Arabic, it would have had a similar name. This fact is a sufficient refutation of the *conjectural* interpretations of certain passages of Scripture that we meet with from time to time. Thus: "Loudolf's conjecture that *dudaim* (mandrakes) were the fruit of *Musa paradisiaca*, (plantain-tree,)" which has been recently revived in a modern work, cannot stand, on account of its name. For the same reason, the conjecture that the grapes which the spies brought from Canaan, were plantains, cannot be sustained. The plantain seems a favorite plant to build fancies upon, Gesenius in defining *teenah*, the fig tree, refers to Gen. 3.7, "Where," he says, "the *Ficus indica* or *Musa paradisiaca*, plantain tree, Engl. with very large leaves seems to be meant." This is perfectly conjectural and is wholly unsustained by the usage of the word, as well as that it bears no resemblance to its Arabic name.—*Mason.* See MUSA.

(6398) PLANTAIN LEAVES, MUSA PARADISIACA. Lin.

Valei elley, TAM. | Maoz ka pat, DUK.

These leaves are used in regimental hospitals, for dressing parts that have been blistered, and men's backs, after punishment.—*Ains. Mat. Med, p.* 191.

(6399) PLANTAIN MEAL, is prepared by stripping off the husk, slicing and thoroughly drying the core in the sun, after which it is powdered and sifted. It has a fragrant odour—and its flavour is said to depend a good deal on the rapidity by which the slices are dried. It

should be husked and sliced by nickel or bamboo knives, as those of steel knives injures the colour of the meal. It is calculated that the fresh plantain will yield 40 per cent of meal, and that an average bunch of 25 lbs. weight will yield 5 lbs. and that an acre of plantain walk of average quality producing 450 bunches during the year, would yield upwards of a ton of meal: In the West Indies plantain meal is largely employed as the food of infants, children and convalescents. In composition the plantain fruit approaches most nearly, in nutritive quality to the potato, and the meal of the plant to that of rice: the following are the proportions of Starch, Sugar &c. and protein compounds, on which depend their nutritive quality.

	Rice.	Potato.	Plantain.
Starch Sugar &c.	87·4	79·0	86·0
Protein Compounds.	7·5	8·9	5·2

—*Simmonds.* Plantain Meal has attracted notice in England. The nutritive quality of this substance, and its chemical composition are found to approach very closely to that of rice. There can be no doubt therefore of the value of this meal, and of the benefit of preparing it, whenever the fruit is produced in larger quantities than it can be consumed.—*M.E.J.R.* See MUSA.

(6400) PLANTAIN SKINS, MUSA PARADISIACA.

Valei palum tole, TAM.

These, as also lime skins, are used by the chucklers in dying leather black.—*Ains. Mat. Med. p.* 129.

(6041) PLANTAIN FIBRE. Almost every part of the plantain, may be converted into fibre, but it most abounds in the stem and leaves, and can be made available for textile or cordage purposes. The combings or tow separated during the preparation of the fibres is of value as a substitute for horse hair, for stuffing mattrasses &c. and the peduncle of the core can be pounded into half stuff for the paper makers and forms an excellent material for the finest or the toughest kinds of paper. While in the West Indies the spiral vessels are employed as tinder. In the process of separation, the stem should be cut down six inches above the ground, and then divided longitudinally into four parts, and the juice expelled by passing each slip longitudinally through the common sugar mill with grooved hard wood rollers, or a mill the rollers of which are three feet long and one foot in diameter. In the process of crushing, the stalks and the harder and softer parts of the stem should be passed through separately, which can be easily effected if the rollers be horizontal. In this way, the produce will be four or five pounds of fibre from each tree. The fibres from the midrib of the leaf are the best, and in general if the stem yield four pound nett of fibre the stalk will give 1 lb. out of four. After the crushing, the fibres are to be well washed and boiled in soda or other alkaline ley to separate the gluten and coloring matter, keeping the fibres from the several parts, quite separate, in this process of boiling. They are then bleached and the highest coloured fibres do not require more than six hours, but the darkest, from twelve to eighteen. The fibre from the stem, is fine white and silky, of considerable length; specifically lighter than Hemp, Flax and Aloe fibre, by $\frac{1}{7}$th or $\frac{1}{5}$th and possessing considerable strength. The fibre of this plant rapidly rots and becomes stiff, brittle and discolored by steeping in the green state, and it has been ascertained by trial that the strength is in proportion to the cleanness of the fibre. If it has been well cleaned, and all the sap quickly removed, it bears immersion in water as well as most other fibres, and has about the same strength as Russian Hemp. The coarse large fruited plantains yield the strongest and thickest fibres; the smaller varieties are suited for weaving, and if carefully prepared, these have a glossy appearance, like silk. But this glossy appearance can only be got by rapid cleaning, before the sap has time to stain the fibres, and it is lost soon if the plant be steeped in water. It yields an excellent substitute for hemp or linen thread; it can be made into string line or rope, and manufactured into cloth. The fine grass cloth, ship's cordage, and ropes used in the south sea Whale fisheries, are said to be made from the fibres of varieties of Musa. As in all the plantain tribe, the leaves yield the thickest and strongest fibres. Though hitherto little employed, there can be no doubt that it is the most conspicuous amongst the fibrous plants of India. It contains a valuable fibre. It is every where cultivated in India for its fruit, an article of universal consumption by the native population, and the stem can always be had in abundance for it. It is a tree which bears fruit only once, and as soon as the fruit has been removed it is cut down. There will therefore be no difficulty in obtaining from this plant alone, a large quantity of fibre of valuable quality, applicable to every species of cloth, or other articles usually made from flax or hemp and of equal quality. The finest plantain fibre when carefully cleaned and dressed, in what may be termed the "fresh process," in contradistinction to the system of rotting the fibres free, has been said to be well suited for the imitation of silk in carriage braid and carpet work. The average value put upon such fibres was said to be £70 per ton, when Russian hemp was selling at £50 per ton. In the West Indies, the total expense of producing a ton of fibres, is calculated at £9 18. 4. It seems worth consideration whether the wild, and at present useless plantains, growing along the foot of the Himalayas and on the Neilgherries may not yield a stronger fibre than any of the cultivated

kinds. The wild fruit is not edible, from its containing many seeds, on the Arracan coast, the layers of the stem of the plantain, termed there *Pa-cha-yoo-ein*, are sold in a dried state, some of it is even twisted into a bast-rope. It would probably command a good price as a cordage or paper material, or for textile fabrics. When the object is to obtain material for the paper maker, it has been suggested to use the implement like a tilt hammer so much employed in India. See MUSA.

(6402) PLASMA. A green, semi-transparent calcedony, having a dark tint, which is supposed to be coloured by chlorite. It is found chiefly in India, and is made into beads, and other ornaments. Occasionally specimens are found among the ruins of Rome.—*Waterston. Faulkner.*

(6403) PLATALEA, a genus of Birds belonging to the family *Ardeidæ*. The peculiar form of the bill in this genus has gained for these birds the common name of Spoonbill. It has the following generic characters:—Bill very long, strong, very much flattened, point dilated and rounded into the form of a spoon or spatula; upper mandible channelled, transversely furrowed at its base; nostrils at the surface of the bill, approximated, oblong, open, bordered by a membrane; face and head partially or entirely naked. Feet long, strong; three toes anteriorly united up to the second joint by membranes or webs; posterior toe touching the ground. Wings moderate, ample; the first quill nearly as long as the second which is the longest. The Spoonbills live in society in wooded marshes, generally not far from the mouths of rivers, and are rarely seen on the sea-shore. Their food consists of small fishes, spawn, and small fluviatile testaceous molluscs, as well as small reptiles and aquatic insects. According to circumstances they build their nests either in high trees, in bushes, or among rushes. Their moult is simple and ordinary, but the young bird does not take the confirmed livery of the adult till the third year; the bill is gradually developed, and appears covered with a membrane. The crest makes its appearance at the second year. The sexes have external distinctions, but the characters are but slightly marked. (Temminck.)—*Eng. Cyc.*

(6404) PLATALEA LEUCORODIA, Linn., the Common White Spoonbill. This species is, there can be little doubt, the Λευκερωδιὸς of Aristotle ('Hist. Anim.,' book viii. c. 3), of which he says that it haunts περὶ τὰς λίμνας καὶ τοὺς ποταμοὺς ("about the lake and rivers"); and which he thus describes:—"In size it is less than the other," the Ἐρωδιὸς (one of the Herons, perhaps *Ardea cinerea*) "and has a broad and long bill;" a description which, when coupled with the white colour indicated by the name, can hardly be deemed inapplicable; nor can the term 'broad' be with any propriety referred to the bill of any of the true Herons. It is the Becquarougeglia (Belon) and Cucchiarone (Bonaparte) of the modern Italians; Pale, Poche, Cueiller, Truble (Belon), and Spatule of the French; Weisser Loffeler and Loffel Gans of the Germans; Lepelaar of the Netherlanders; Llydon Big of the Welsh; and Spoonbill and White Spoonbill of the English. This bird has a very full long occipital crest, formed of loose and subulate feathers. It feeds on very small fish, spawn, testaceous mollusca, insects and aquatic worms, small reptiles, and the roots of some weeds and grasses. The Common Spoonbill haunts the mouths of rivers. Its nest is built sometimes on lofty trees, sometimes in rushes and reeds, according to circumstances and the eggs are from two to four in number, generally three, sometimes entirely white, but most frequently white marked with obscure red spots. They bred annually in the time of Ray in a wood at Sevenhuys, not far from Leyden, but the wood has been long destroyed.—*Eng. Cyc.*

(6405) PLATANACEÆ: PLANES, a natural order of Exogenous Plants. The species are amentiferous trees or shrubs, with alternate deciduous palmate or toothed stipulate leaves, and unisexual naked flowers in globose catkins. The barren flowers with stamens single, mixed with scales, Fertile flowers with ovary 1-celled, style thick and subulate. Ovules 1-2, orthotropal; suspended. Nuts clavate, with a persistent style. Seeds usually solitary and albuminous; radicle inferior. They are natives of the Levant and North American chiefly. They are fine trees, but their timber is not durable.

(6406) PLATANUS ORIENTALIS, Oriental Plane, has palmate leaves resembling those of the common Sycamore. It grows in the western parts of Asia, and extends as far east as Cashmere. Its wood is fine-grained and hard, and when old it acquires dark veins so as to resemble walnut-wood. The tree was valued for its shade by the Greeks and Romans, and it was held sacred in the East. *P. occidentalis* is found in most parts of North America, from Mexico as far as Canada. The timber is of a reddish colour, and will not bear exposure to the weather. There is but this one genus in the order and six species. The family resembles *Artocarpaceæ* and *Altingiaceæ*.

(6407) PLATINA. A metal of a colour between steel-gray, and silver-white, which, in respect of scarcity, beauty, ductility, and indestructibility, is hardly inferior to gold. It is found in the metallic state in Brazil and Peru, in Antioquia in South America, in Estremadura, in Spain, and latterly, in considerable quantities in the Uralian Mountains. The general appearance of it in the rough state, is that of small grains or scales darker than silver, and extremely heavy. This metal is peculiarly valuable in many chemical applications, and is much employed for crucibles, retorts for the distillation of sulphuric acid, mirrors for reflecting telescopes, &c. In Russia it is made into coins.—*Faulkner.* Platinum,

or Platina, is an important metal, although it was not known earlier than about the middle of the last century. It was first made known in Europe by Mr. Wood, assay-master in Jamaica, who met with its ore in 1741. In 1750 he published a paper upon it in the 'Philosphical Transactions.' The name of this metal is the diminutive of 'plata' silver, given to it on account of its colour, and it was originally called Platina del Pinto, because it was found in the auriferous sand of the river Pinto. It has since been found in Brazil, Colomba, St. Domingo, and in the Ural Mountains.—*Eng. Cyc.*

(6408) PLATYLOBIUM TRIANGULARE. LEGUMINOSÆ. These are free flowering shrubs, with pretty orange, yellow, or red coloured flowers, and are readily grown from seed in any tolerable garden soil.—*Riddell.*

(6409) PLATYSTEMON CALIFORNICUM. RANUNCULACEÆ. These are annuals with cream coloured flowers, natives of California, and said to grow best in sandy loam.—*Riddell.*

(6410) PLECTOCOMIA. A genus of palms growing in Malacca, Java, Assam and the Cossya Hills, with leaves of great length, having a hook at the end by which to support themselves.—*Seeman.* Plectocomia is the *Rhenoul* of the Lepchas and is not a very large plant: but it climbs lofty trees and extends 40 yards through the forest, 6500 is the upper limit of the Palms in the Sikkim Himalayas, the *Rhenoul* alone attaining this height.—*Hooker Vol.* I, *p.* 147.

(6411) PLECTRANTHUS (from πλῆκτρον, a cock's spur, and ἄνθος, a flower, in reference to the corolla being spurred or gibbous above the base), a genus of Plants belonging to the natural order *Labiatæ*. It has a campanulate 5-toothed calyx in the floriferous state; the teeth equal or the upper one largest. The corolla with an exserted tube; the upper lip from 3-4-cleft, the lower one entire, usually longer and concave. There are 4 stamens, declinate, didynamous, the lower ones longest; free toothless filaments; ovate uniform anthers. The species are herbs, subshrubs, and shrubs. There are 45 species of this genus described, which are of easy culture and propagation.—*Eng. Cyc.*

(6412) PLECTRANTHUS AROMATICUS. FRAGRANT PLECTRANTHUS.

Pathur-choor. HIND.

Cultivated in gardens at Ajmeer.—*Genl. Med. Top. p.* 200.

(6413) PLECTRANTHUS CORDIFOLIUS, a very aromatic plant of India of the family LABIATÆ.—*O'Shaughnessy, page* 491.

(6414) PLECTRANTHUS CRASSIFOLIUS is esteemed in India both as a perfume and a spice, being equally valued in the toilet and the kitchen. The Patchouly, so inimical to vermin and so efficacious in preserving cloths from moths, was said to be the leaves of *P. graveolens*, which have a very powerful odour, but the comminuted state in which it is imported renders this uncertain.—*Eng. Cyc.*

(6415) PLECTRANTHUS RUGOSUS. Rottler.

Sirroo Kaluig, TAM.

This seems peculiar to the Tinnevelly country; and has a wholesome pleasant tasted, bulbous root, much eaten by the Natives particularly during the period of their great festivals. Its leaf is rough and not unlike that of Burrage.—*Ainslie, p.* 250.

(6416) PLEURONECTES SOLEA. THE SOLE.

Naak meen, TAM.	Ekan leda MALAY.
Kowlie mutchie, DUK	

Ains. Mat. Med. p. 155.

(6417) PLEUROPTRA, a tribe of *Mammalia* generally known as Flying Lemurs (*Galeopithecus* of Pallas; Flying Cats and Flying Foxes of voyagers). They are generally arranged under the order Carnassiers, and some authors place them in the division *Cheiroptera*; but they differ from the Bats inasmuch as the toes of their anterior extremities, which are all furnished with sharp claws, are not more elongated than those of the hind feet, so that the membrane which occupies the interval between the extremities to the sides of the tail can hardly operate in executing more than the functions of a parachute. The dentition, according to Mr. Waterhouse, is as follows:—

$$\text{Incisors},\frac{2\text{-}2}{4};\ \text{Canines},\frac{0\text{-}0}{1\text{-}1};\ \text{Molars},\frac{2\text{-}2}{2\text{-}2};\ \text{Molars},\frac{4\ 4}{4\text{-}4}=\frac{34}{34}$$

Cuvier states that the *Galeopitheci* live on trees in the islands of the Indian Archipelago, and there pursue insects, and perhaps birds, as their prey: judging from the detrition of the teeth with age, he thinks that they must also feed on fruits. They have a very large cæcum. In their teeth they present many analogies to the *Lemuridæ*. Dr. Gray makes the *Galeopithecidæ* the fourth family of the *Primates*, and places it between the *Lemuridæ* and *Vespertilionidæ*. ('Outline, &c., in Ann. of Philosophy,' 1825.) Three species have been recorded:—1, *Galeopithecus rufus*, Geoff., Audeb. (*Lemur volans*, Linn.); 2, *G. variegatus*, Cuv., Geoff.; 3, *G. Ternatensis*, Geoff.: but the general opinion seems to have been that one only, the (*Lemur volans* Linnæus) had been satisfactorily made out. Mr. Waterhouse has however described two species, of which the following are the characters:—

(6418) *Galeopithecus Temminckii*, measures about 2 feet in total length, and its skull was 2 inches 11½ lines in length. The anterior incisors of the upper jaw is broad and divid-

ed by two notches into three distinct lobes; the next incisor on each side has its anterior and posterior margins notched; and the first molar (or the tooth which occupies the situation of the canine) has its posterior edge distinctly notched. This tooth is separated by a narrow space, anteriorly and posteriorly, from the second incisor in front and the second molar behind; the temporal ridges converge towards the occiput, near which however, he observed, they are separated usually by a space of about four lines. This is probably the *G. volans* of authors; but the identity cannot be said to be certain.

(6419) *Galeopithecus Philippinensis* is described by Mr. Waterhouse as being usually about 20 inches in length, and its skull as measuring 2 inches 7 lines in length. He observes that this species may be distinguished from *G. Temminckii* by the proportionately larger ears and the greater length of the hands. The skull is narrower in proportion to its length, the muzzle as broader and more obtuse, and the orbit as smaller. The temporal ridges generally meet near the occiput, or are separated by a very narrow space. The anterior incisor of the upper jaw is narrow, and has but one notch; the next incisor on each side is considerably larger, longer, and stronger than in *G. Temminckii*, and differs moreover in having its edges even—the same remark applies to the first false molar. In this species the incisors and molars form a continuous series, each tooth being in contact with that which precedes and that which is behind it. The most important difference perhaps which exists between the two species in question consists in the much larger size of the molar teeth, in the smaller skull, the five posterior molars occupying a space of 10 lines in length, whereas in *G. Temminckii*, a much larger animal, the same teeth only occupy 9 lines. (' Zool. Proc,' 1839.)

(6420) PLOCARIA, a genus of Plants belonging to the alliance *Algales*, the order *Ceramiacea*, and the sub-order *Sphærococcea*. One of the species, *P. Helminthocorton*, is called Corsican Moss, and has a considerable reputation as a vermifuge. It is a native of the Mediterranean.—*Eng. Cyc.*

(6421) PLOCARIA CANDIDA. Fucus Amylaceus.

Kyouk-pwen, Burm.

A sea weed, abundant on the Tenasserim coast, and exceedingly valuable for its nutritious and medicinal properties for invalids. It was first brought to public notice by Dr. O'Shaughnessy as the Edible moss of the Eastern Archipelago, and referred by him to the genus fucus. The fructifications however being in small tubercles, the Rev. Mr. Mason considers it as a species of Agardh's genus, Sphærococcus which now constitutes a member of the genus Plocaria. It is an allied species with the Ceylon moss (Gigartina lichenoides) first described as fucus amylaceus by Dr. O'Shaughnessy, the Plocaria lichenoides of Mr. Mason; also with a species found on the coast of Devonshire in England; Pl. compressa: with the Corsican moss of the Mediterranean P. Helminthochorton; also with the Agar-agar Pl: tenax a species used in China, as a substitute for glue and gum *Arabic*, but differs from the Irish moss or Chondrus crispus; and is not of the same natural family as the Iceland moss which, indeed, is a lichen, the Certraria islandica. The Tenasserim moss is said to be superior to all others, as it is wholly free from the bitter principle which renders other fuci so objectionable; but Mr. Mason seems to consider it identical with the Ceylon moss, for he gives the same account of it as Dr. O'Shaughnessy gives of that from Ceylon. It contains he says a considerable proportion of starch, and was hence named by Dr. O'Shaughnessy, the starch fucus, F. Amilaceus but its specific name has been since changed to *candida*, white, probably from a mistaken idea that the substance is naturally white, whereas it becomes so only by bleaching in the sun; its natural tint, is a shade between olive and purple, such as the natives designate red. According to Dr. O'Shaughnessy's analysis it contains as follows:

Vegetable jelly, ...	54.5
True starch, ...	15.0
Wax, a trace	0.5?
Ligneous fibre, ...	18.0
Gum, ...	4.0
Sulphate and muriate of soda,...	6.5
Sulphate and phosphate of lime, ...	1.0
Iron, a trace, ...	0.4?
	100.0

On the best mode of preparing it for use he adds: "In the first place, from the tendency of *pectin* or vegetable jelly to form insoluble compounds with saline and earthy bases, it is necessary to steep this fucus for a few hours in *cold rain water* as the first step in its preparation. This removes a large portion, if not the entire, of the sulphate of soda, leaving all the gelatine, and starch. It should next be dried by the sun's rays, and *ground to a fine powder*; I say *ground*, for cutting or pounding, however diligently or minutely performed, still leaves the amylaceous globules so mechanically protected, and so closely involved in an external sheath of tough ligneous fibre, that scarcely a particle of the starch can be extracted by boiling, even though the decoction is prolonged for several hours. When *ground*, boiling for 25 minutes or half an hour dissolves all the starch and gelatine. The solution while hot should be passed through muslin or calico, and thus the ligneous fibre is

removed; lastly, the strained fluid should be boiled down till a drop placed on a cold surface gelatinizes sufficiently. "With milk and sugar, and flavoured with lemon juice or sherry, this substance when prepared as now directed, would afford the invalid a pleasant article of diet, especially at sea, where other jellies or their materials cannot be so easily preserved. As this fucus is found abundantly on the eastern coast of Bengal, he entertained considerable hopes of its being hereafter found available also in several processes of art and various manufactures." —*Mason.*

(6422) PLOCEINÆ, a sub-family of *Fringillidæ*. The genus *Ploceus* (Weavers, Tisserins of the French) is thus defined by Mr. Swainson:—Size small. Bill conic, but with the culmen slightly bent, and the tip entire. Under mandible less thick than the upper. Claws large, very long. Wings pointed; but the first quill remarkably short and spurious. It inhabits the Old World only.—*Eng. Cyc.* Next to the sub-genus *Vidua*, in Mr. Swainson's arrangement, come the following:—

(6423) *Euplectes* (Sw.)—Bill shorter than the head. Nostrils round, partly concealed by the frontal feathers. Wings short; the second quill shorter than the third; tertials as long as the primaries. Tail short, even, or very slightly rounded. Feet large, gracile. Toes very long and slender; the lateral of equal length. Claws slender, very slightly curved.

(6424) *Ploceus* (Cuv.).—Bill considerably lengthened, as long as the head. Nostrils almost naked. Wings moderate; the second, third, fourth, and fifth quills nearly equal; tertials shorter than the primaries. Tail short, even. Feet large, thick. Toes robust; the lateral equal. Claws strong, thick, fully curved.

(6425) *Symplectes* (Sw.).—General structure of *Ploceus*; but the bill is more compressed, the commissure curved, but neither sinuated nor toothed. Wings short, rounded; the first quill half as long as the second, which, with the third, is graduated; the next three are nearly equal, and are the longest. Tail moderate, even. Feet strong. The middle toe abbreviated; inner toe shorter than the outer; hinder toe long, equal to the middle toe.

(6426) *Amadina* follows in Mr. Swainson's arrangement, and he speaks of the genus *Ploceus* thus defined as by far the most beautiful of the division of *Coccothraustina*. "It is," says he, "composed of the Weavers, a name given them on account of that surprising skill with which they fabricate their nests."

(6427) PLOMBAGO, Carburet of Iron. Black Lead, Plumbago. Is said to be occasionally sold for antimony in the bazars. It is found in Ceylon and in Travancore, also in the Northern Circar mountains in the Vizagapatam districts, though I am not aware of any having found its way into the market but I understand it has been procured thence by the proprietors of the Bimlipatam sugar works for use in machinery. I have had some of good quality for common purposes, found in the hill on which Capt. Orr's house stands.—*Rohde, M.S.S.* Plumbago abounds in the hills skirting the Western boundary of the Vizagapatam district. The deposits have never been worked, and that which is brought to the Coast is coarse and impure.—*M.C.C.* Of samples of plumbago from several localities, the finest and most varied series both as regards size and quality were those exhibited by General Cullen from Trevandrum. One large block occurs along with laterite and contains some pieces the size of a walnut, nearly equal to the fine kinds of Cumberland black lead. Other large blocks nearly a foot in cubic measurement appear of a softer and coarser quality. They have been sawed through, but are not so compact as the brightest portions of the first named block. This plumbago or graphite is well suited for the manufacture of ordinary pencils or for making crucibles. Mr. Caldecot exhibited some very fair samples from the same locality; the Zemindar of Vizianagrum also exhibited some fair specimens. Lieut. Evans, 51st Regiment M. N. I., exhibited plumbago of good quality from Ceylon, and of indifferent quality from beds of shale that accompany iron ore at Malacca. Some indifferent specimens of plumbago were also exhibited along with iron ore and slaty shales from Cuddapah.—*M. E. J. R.* Lately there have been made further observations on the Graphite or Plumbago of Kumaon and Travancore by Dr. Forbes Royle M. D. with an Extract from a letter from the Resident of Travancore and Cochin dated 9th February 1857. This Mineral was formerly found in its most pure state in Borrowdale in Cumberland, which indeed was the only Mine which produced Lead of that fine quality requisite for the manufacture of Drawing Pencils. The Cumberland Mines have been wrought since Elizabeth's time; pure Cumberland lead costing as much as from 30 to 40 shillings a pound. The lead is not found in veins but in detached pieces, so that the supply is occasionally irregular and the search for it laborious and often fruitless. Inferior descriptions of lead come from Spain and Ceylon, and are used in the manufacture of crucibles and of the inferior sort of Pencils and in polishing Cast Iron. At present Mr. Royle says, finely powdered Graphite can, by an extreme degree of pressure, be rendered nearly as compact as the best natural Graphite, or we should be without any more good drawing Pencils. The great Manufacturers of Pencils in England reported the Kumaon and Travancore specimens as quite useless for the manufacture of black lead pencils, observing that they could not use the specimens in the state

in which they had been sent without damaging their machinery, at the same time they could not conceive why purer specimens should not be found in the same locality. In regard to the objections made to the specimens forwarded, General Cullen, the Resident of Travancore, remarks that one motive of their selection was to exhibit the matrix or Laterite rock in which they were found. General Cullen has addressed a further report on the Plumbago or Graphite of Travancore. Two varieties of Graphite are found in Travancore, one in thin laminæ, another granular, and he sent specimens of both to the Exhibition of 1851. The granular or fibrous variety, "I have only yet discovered in two localities and both of them in laterite, a few feet only below the surface. One locality is about 5 or 6 miles N. E. of Trevandrum and the other about 12 or 14 miles N. E. I brought in from this latter locality on my visit to it, about 3 cwt. Some small deposits are also found immediately on the W. of the town of Trevandrum, but I have not yet heard of any other deposits of this granular variety though I think it probable they exist. Graphite in thin scales or laminæ is common nearly throughout the laterite tracts of Travancore and Cochin, but more or less abundant in particular places. It is found in some places in lamina of considerable size, particularly in a laterite hill about 25 miles N. E. of Trevandrum at a place called Caviatteucoodul, near the foot of the Ghât mountains. Having some specimens of this variety by me, I forward them. It is also found in laminæ of good size in the disintergrated gneiss of the Ghâts on the Tinnevelly side, also common in the Kunker or Travertine deposits near Culdacoorche and Ambasamoodrom. The Vizagapatam Graphite is perhaps also found in laterite, of which there is a large deposit at Bimlipatam. The objections made to the specimens of Graphite sent to the London Exhibition of 1851, were because of the impurities attached to it, but one motive in the selection of the specimens forwarded was to exhibit the matrix or laterite rock in which they were found. M. L S. Journal.—*General Cullen.*

(6428) PLOUGHING. The Chinese annual ceremony of ploughing is of very ancient origin. At Peking, it consists in ploughing a sacred field with a highly ornamental plough kept for the purpose, the Emperor holding it while turning over three furrows, the princes five, and the high ministers nine. These furrows were, however, so short that the monarchs of the present dynasty altered the ancient rule, ploughing four furrows and returning again over the ground. The ceremony finished, the emperor and his ministers repair to the terrace, and remain till the whole field has been ploughed. The ground belongs to the temples of Heaven and Earth, on the south of the city, and the crop of wheat is used in idolatrous services. The rank of the actors renders the ceremony more imposing at Peking, and the people of the capital make more of it than they do in the provinces. A monstrous clay image of a cow is carried to the spot, containing or accompanied by hundreds of little similar images; after the field is ploughed it is broken up, and the pieces and small images are carried off by the crowd to scatter the powder on their own fields, in the hope of thereby insuring a good crop. The heads of the provincial governments, the prefects and district magistrates, go through a similar ceremony on the same day. In Ningpo, an eye-witness describes the principal features of the ceremony as consisting in a solemn worship by all the local officers of a clay image of a buffalo and an idol of a cowherd. The prefect then ploughed a small piece of ground, and he and his associates dispersed till the morrow, when they came together in another temple at dawn. Here a series of prostrations and recitals of prayers were performed by the "fathers of the people" in their presence, some of whom seemed to have no respect for the worship they were engaged in, while others evinced deep reverence. As soon as this was over, the clay ox was brought out, and a procession consisting of all the officers passed around it repeatedly, striking the body at a given signal, and concluding the ceremony by a heavy blow on the head. The crowd then rushed in and tore the effigy to pieces, each one carrying off a portion to strew on his fields.—*Williams' Middle Kingdom, Vol.* II. *page* 109.

(6429) PLUMBAGO. *Plumbaginaceæ.*—The Lead Wort. (White) P. Zeylanica (Red) P. Rosea (Blue) P. Capensis.—The White Plumbago is common; so are the other varieties. The red and blue blossom throughout the year; but the latter, which is the handsomest of the whole, and introduced from the Cape, is by far the most esteemed. Is propagated by layers.—*Riddell.* These three different species of plumbago, the red, the white, and the blue flowered, are common in Tenasserim gardens; and the first two are cultivated by the Burmese for the vesicatory power of their roots.—*Mason.*

(6430) PLUMBAGO ZEYLANICA (Flower white)

(6431) PLUMBAGO CAPENSIS (Flower blue.)

(6432) PLUMBAGO EUROPÆA, South of Europe.

Chitra vani, Sans.

An erect, branching, smooth, herbaceous shrub. The whole plant, especially the root, is very acrid, and applied as paste to the skin, acts as a powerful vesicatory. Given internally in small doses, it is said to be a very efficacious emetic, but we would deem its administration as dangerous as that of cantharides. The bruised

root has been employed in Europe as an application to cancer, as a counter-irritant in toothache, and as a remedy for the itch.—*O'Shaughnessy, page* 508.

(6433) PLUMBAGO ROSEA. Lin.

Lal chitra, Duk.	Chitra, Beng.
Cditraca, Sans.	Shiturridge, Arab.
Chittra molum and kodivaylie, and Shencodie-vaylee, Tam.	Tumba codiveli, Hort. Mal.
Chitturmol, Duk.	Yerra Chittramoolum, T.
Chita, Hind.	Aroona Chitraca, Sans.

A native of various parts of the East Indies, an erect, herbaceous plant with a round striated stem, and ascending or erect branches. This like the Chittramoolum is a plant of the class Pentandria and order Monogynia and is nearly similar to it in its natural qualities. The bruised root tempered with a portion of same bland oil, is used as an external application in Rheumatic and Paralytic affections. It is also prescribed internally in powder, in small doses, for the same complaints.—*Ains. Mat. Med. p.* 112. The properties of this species and of the *P. scandens* and *zeylanica* are nearly identical. A paste made with rice congie and the bruised bark is applied by the natives to buboes in the incipient states: it acts as a vesicatory. Dr. O'Shaughnessy made numerous clinical experiments with the bark of the plumbago root of various species, especially the *P. rosea*, rubbed into a paste with water and a little flour, or congie; it occasions pain in about five minutes, which increases in severity till in a quarter of an hour it is equal to that of a cantharides blister or mustard sinapism. If the paste be removed in half an hour the pain is soon allayed, and in a period of 11 to 18 hours a large uniform blister, full of serum, is occasioned. The blistered surface heals readily without unpleasant ulceration. Applying Plumbago Rosea in the native, the skin in a few minutes is intensely blackened; in white-skinned persons a deep redness is occasioned. In all chronic cases and in many acute diseases this blister will prove an effectual and very cheap substitute for cantharides, over which it possesses the peculiar advantage of never producing strangury or any other form of irritation of the urinary organs. Dr. O'Shaughnessy speaks from the experience of from 3 to 400 cases. His experiments lead him to believe that the blistering quality resides in the Plumbagin, but on this he was as yet unable to speak in positive terms. The root, in various forms, is much employed as a poison in India; and as an irritant to occasion abortion it is introduced into the vagina and applied directly to the neck of the uterus. In a criminal case of the former kind, in 1837, Dr. O'Shaughnessy, succeeded in detecting the poison by acting on the contents of the stomach with alcohol, concentrating the tincture, re-dissolving in a small quantity of boiling water, and adding the sub-acetate of lead, by which the very characteristic red colour was immediately occasioned. By a modification of this process two grains of the powdered bark may be detected in a pint of a mixture of milk, blood, and various articles of food.—*O'Shaughnessy, page* 509—10.

(6434) PLUMIERIA. Several species of this genus, natives of Jamaica, Surinam, Brazil, the Malayan Archipelago, and Cochin China, are used as drastic cathartics.—*O'Shaughnessy.*

(6435) PLUMIERIA ACUMINATA. Apocynaceæ.

Gobur-Chumpa. Duk.

A small elegant tree, common; flowers white and yellow, tinged with red, very fragrant. A pure white caoutchouc is obtained from this tree.—*Riddell.* It is abundant and luxuriant in the Pinjore valley. (*Royle*)—*O'Shaughnessy, p.* 449. China champac. This, a small South America tree, is called by the Burmese, chúna champac, Its straggling, and often leafless branches shoot out from their extremities delicate orange-colored blossoms, tinged with red, and of sweetest fragrance.—*Mason.*

(6436) PLUMIERIA ALBA.

Gulachin, Duk.

The White Chumpa.

(6437) PLUMS. The well-known fruit of a tree (*Prunus domestica*), indigenous to the greater part of the Northern Hemisphere. No less than 274 varieties of this fruit are enumerated. Dried plums form an article of commerce under the names of prunes and prunellas.—*Faulkner.*

(6438) POA (the Greek πόα 'grass'), a genus of Grasses belonging to the tribe *Festuciueæ*. This tribe is characterised by very short styles, protruded stigmas, and the glumes shorter than the lowest flower. The genus *Poa* has its glumes rather unequal; the outer palea with 3 or 5 nerves, membranous below, scarious at the tip, compressed, keeled, unarmed; the styles terminal. The species of this genus are very numerous, constituting the commonest weed that follow the migrations of man, and generally containing a sufficient quantity of nutritive matter to render them fodder for various animals. Thirteen species of this genus are described by Babington as natives of the British Islands. Of these the most common are the *P. annua* and *P. pratensis*. The former is perhaps the commonest of British plants, springing up on every neglected spot around the habitations of man. The latter is known by the name of the Smooth-Stalked Meadow-Grass, and is found in most pasture lands. *P. nemoralis*, the Wood Meadow-Grass, is also a common grass in shady places. Many of the recent genera of Grasses were formerly referred to the genus *Poa*.—*Eng. Cyc.*

The sacred grass of the Hindoos, the *dab* or *koosha* of the Brahmins (*Poa cynosuroides*), is made into rope in North-West India. Species of Saccharum are used for thatching and for screens, and some for making writing-pens and for The fibres of the *Andrachus* or Vetiveyr are more remarkable for their agreeable odour than for their tenacity, while the Bamboo, the most gigantic of grasses, might be enumerated with timbers rather than with fibres, though its split stems are often employed for making mats in India, and the young shoots for paper-making by the Chinese. Many other of the grasses might be converted into half-stuff for paper-makers, and have the great advantage of affording large quantities of a cheap material.—*Royle.*

(6439) PODA WOOD.

Poda, Tel. | Pallas, Hind.

(6440) PODALYRIA GENISTOIDES. Leguminosæ. These are pretty shrubs with silky leaves, and should be grown in a light garden soil, their colours are mostly white, purple, blue or red, and should be raised from seed.—*Riddell.*

(6441) PODOLEPIS GRACILIS. Compositæ. The stems of these plants are covered with scales, the flowers are white, yellow and pink, these plants are adapted for borders, and may be raised from seed.—*Riddell.*

(6442) PODOPHYLLUM PETLATUM, (may-apple) is a native of the United States, where the root is considered to be a valuable, and powerful cathartic.—*O'Shaughnessy, page* 170.

(6443) PODOPHYLLUM EMODI, Wall. Occurs in Nipal and Kemaon, and on the Choor mountain in the Himalayas, at an elevation of 10,000 feet. A specimen of the root was forwarded to the Committee investigating the Bengal drugs, by Dr. Falconer, of Seharunpore, but the quantity obtained was too small for the requisite experiments being instituted upon its virtues.—*O'Shaughnessy, page* 170.

(6444) PODOPHYLLUM HEXANDRUM, was found by Dr. Royle on the Kedarkanta mountain, at an elevation of 12,000 feet.—*O'Shaughnessy, page* 170.

(6445) PODOSTEMON. Of this genus of plants, Dr. Wight in Icones gives, P. dichotomus, 1916-2; elongatus, 1917-1; griseus, 1918-3; olivaceus, 1918-2; rigidus, 1916-5; subulatus, 1918-1; Wallichii, 1916-1; Wightii, 1916-3.

(6446) PODOSTEMON. One species grew near the Jyntea Hills on the stones at the bottom of the Oongkot: it is a remarkable water-plant resembling a liver-wort in its mode of growth. Several species occur at different elevations in the Khasia, and appear only in autumn, when they often carpet the bottom of the streams with green. In spring and summer no traces of them are seen; and it is difficult to conceive what becomes of the seeds in the interval, and how these, which are well known, and have no apparent provision for the purpose, attach themselves to the smooth rocks at the bottom of the torrents. All the kinds flower and ripen their seeds under water, the stamens and pistil being protected by the closed flower from the wet. This genus does not inhabit the Sikkim rivers, probably owing to the great changes of temperature to which these are subject.—*Hooker Him: Jour: Vol.* II. *page* 314.

(6447) PODOTHECA CAPITATA. A yellow flowering plant of no great beauty—readily cultivated from seed.—*Riddell.*

(6448) POEE, Basella Alba et Rubra. Malabar Nightshade. This is a twining, succulent plant, with smooth fleshy leaves; it grows very rapidly and is generally cultivated as a spinach. There are two sorts.—*Jaffrey.*

(6449) POGOSTOMON. A genus of plants, one of which, P. Pachouli, furnishes the fragrant herb of that name, Dr. Wight gives in Icones, Pogostemon Heyneanus, 1440; hirsutus, 1442; rotundanus, 1441; speciosus, 1443. See Patchouli.

(6450) POINCIANA, a genus of Plants belonging to the natural order *Leguminosæ*. *P. aculeata*, or the Barbadoes Flower-Fence, is a tropical bush, about ten feet high, with bipinnate leaves, obovate leaflets, prickly branches, large terminal corymbose masses of inflorescence, covered with showy yellow or red flowers, having singularly long stamens. It has acquired its name from having been used, on account of its prickly branches, as a material for hedges in the West Indies, for which however it is ill adapted, because its branches are not much subdivided, and are always naked next the root. It is among the most beautiful of plants, and is chiefly on that account cultivated in the West Indies, to which it was introduced from the East Indies, where it is common in gardens, flowering and seeding all the year round. The leaves when bruised have a smell of savin, and are said to have the power of bringing on abortion. They are well known to be purgative, and to have been used as a substitute for senna. According to Roxburgh, the trunk of this little tree, or large shrub, when old, is constantly hollow, and occupied by a large red dark brown ant. From this place, when disturbed, the ants issue in swarms, and inflict a severe and painful bite on their disturbers.—*Eng. Cyc.*

(6451) PONICIANA ELATA. Willow.

Sooncaihla, Tel. | Neerangi, Can.
Pada Narrayan, Tam.

This Willow has been extensively and successfully used by Major Lawford, Madras Engineers, as a protection for the footings of rivers and channel banks. Where it is not wanted to spread
